In Chapter I the author deals with the effect of beating on the character of the stuff with regard to physical changes, such as shortening of the fibres and of "wet beating" which may result in both physical and chemical changes of the fibres.

Chapter II, "The Mechanics of the Beating Tackle"; Chapter III, "The Theory of Beating"; Chapter IV, "The Beating Pressure"; Chapter V, "Influence of Pressure and Consistency on the Beating Action," contain a mass of detail which will be found of the utmost interest to all concerned with the manufacture of paper.

In Part II, Chapter I to IV, the author discusses the results of exhaustive experiments into the power consumption of beaters.

The study of the "Conditions Governing the Formation of Fibrages" dealt with in Part III, to which hitherto but little attention has been paid, will be found of special interest. Dr. Smith has made a careful study of this subject, which is one of the most important factors in determining the efficiency of a beater.

We are indebted to Mr. C. F. Cross for the "simple descriptive word" Fibrage, which means "the fibre attaching itself to the bars and brought under the direct milling action between the bars of the roll and bed plate."

Those who are unable to follow the mathematical treatment of the subject will find a very useful summary at the end of the book, in which the author's conclusions are set out in non-mathematical terms.

The book should be carefully studied by every papermaker and papermaking engineer.

The industry is greatly indebted to the Technical Section of the Papermakers' Association of Great Britain and Ireland for publishing this work in English, and last, but not least, to Major Marx for his excellent translation.

J. Huebner

The Design and Working of Ammonia Stills. By P. Parrish, A.I.C., M.I.Chem.E. Pp. xvii+283. London: Ernest Benn, Ltd., 1924. Price, 40s. net.

Mr. Parrish's book should receive a hearty welcome from all who are connected with the working of plant for the recovery of ammonia from any form of ammoniacal liquor, for though there are other books containing general descriptions of ammonia-plant, there are none within the reviewer's knowledge dealing with the matter in detail from the point of view of working the plant in such manner as to obtain from it the greatest efficiency and economy in manufacturing costs. This book well fills the gap, as would be expected in view of Mr. Parrish's extended experience in the working of these plants and the long and careful study he has made of the different processes involved, and of the principles on which they depend. Whilst it is probable that there will not be universal agreement with every one of Mr. Parrish's conclusions, even those who differ from him on some points will gain much from a study of the book whether they are concerned with the daily working of the plant or the design of new and better apparatus for the purpose.

What may be termed the leading "motif" of the book is economy in steam, and consequently in fuel consumption, a matter very largely neglected in the past. This neglect was chiefly due to the fact that the users of such plant were, for the most part, gas undertakings or coke oven installations, which happened to have available supplies of poor fuel suitable for the purpose which were barely saleable, and, in consequence, economy of such fuel made but a small showing in reducing manufacturing costs. The great rise in the commercial value of even such low-grade fuels, has, however, entirely altered the position, and a reduction in fuel consumption is now realised as imperative, even by those who formerly regarded this as unimportant. But, although steam and fuel economy may be regarded as the main theme, adequate consideration is also given to the underlying principles of the still and the accessory parts of the plant, such as preheaters, dephlegmators liming apparatus and coolers; the manufacture of concentrated gas liquor, concentrated ammonia liquor, and liquor ammonia are all dealt with, as well as the difficult problems associated with the satisfactory handling of the waste gases and waste liquor produced in the process, and directions are indicated in which these are capable of improvement. The most noticeable omission in the book is that nothing is included with regard to the manufacture of ammonium sulphate from the gases given off from the stills, although (except for the ammonia-soda process, where the

ammonia from the stills is, for the most part, used over and over again and only losses having to be made good) by far the greatest amount of ammonia evolved from the stills is made direct into sulphate.

The book is well printed on good paper, and the illustrations are numerous and, for the most part, good and clear. There are, however, some defects which should be remedied in future editions. For example, in Fig. 167, representing diagrammatically the still used in the ammonia-soda process, the arrangement is not very clear, and part of the figure seems to have wandered into Fig. 168 on the next page. Further, where the illustrations are numerous, these sometimes get separated by several pages from the descriptions, which is somewhat exasperating to the reader, and though probably to some extent unavoidable, might be made less extensive. The number of typographical errors is also rather large, though these are, for the most part, confined to transposition of figures, and especially to the chemical formulæ and equations, which suffer rather severely in places.

H. G. COLMAN

1. CHEMISCHE REAKTIONEN IN GALLERTEN. By R. ED LIESEGANG. Pp. 90. Dresden and Leipzig: Theodor Steinkopff, 1924. Price \$0.85 net.

2. LICHT UND FARBE IN KOLLOIDEN. By WOLFGANG OSTWALD. Pp. XIV. + 556. Dresden and Leipzig: Theodor Steinkopff, 1924. Price \$7.60 net.

1. The study of reactions in jellies is one of the most fascinating lines of colloidal research, owing partly to the beauty of many of the results, and partly to the hope, remote and tantalising though it is in many instances, of their throwing light on the origin of natural structures. The subject bears on so many different disciplines that the literature is even more widely scattered than that on other branches of colloid chemistry, and the author has done a service to students by presenting a brief but quite adequate account of our present knowledge. A short introduction is followed by a description of the experimental technique of diffusion and precipitation experiments, a discussion of Pringsheim's rule for the direction in which the reaction proceeds, and chapters dealing with apparent *actio in distans*, the degree of dispersity and crystallographic peculiarities of the precipitates formed in jellies. The rest of the volume is devoted to the phenomenon of periodic precipitation now generally associated with the author's name, the closely related "rhythmical crystallisation," and their bearing on natural structures. Few readers, unfamiliar with the literature, would gather from these chapters how important have been the author's own contributions; wherever possible, he describes the work of other investigators rather than his own. Even the illustrations, which are well chosen and reproduced, are largely taken from the papers of other authors.

The work should be useful to a large circle of readers and will probably tempt most of them to make at least one set of "Liesegang rings."

2. This large volume is described as the first part of a treatise on the optical properties of colloidal or, more generally, disperse systems. A comparison with standard works, such as Freundlich's "Kapillarchemie," which devotes a total of about 25 pages to these properties, is all that is necessary to impress the reader with the magnitude of the task accomplished by the author. An immense range of literature has been drawn upon, and the material has been marshalled so as to exhibit the two aspects which the author emphasises in his other works; the continuity of phenomena, from coarse dispersions to molecular solutions, and the variation of any one property with the degree of dispersity. The matter is treated under five principal headings: I. Turbidity and the Tyndall phenomenon; II. The ultra-microscope and the qualitative and quantitative ultra-microscopic investigation of disperse systems; III. Polarisation and optical activity; IV. Absorption and colours, and V. Refraction and dispersion in disperse systems.

In the first section the factors which cause turbidity in disperse systems, viz., refraction, reflection and diffraction at the interface, and their relative share with varying degree of dispersity, are discussed at great length for both dielectric and metallic particles. The chapter on ultra-microscopy is by far the most exhaustive treatment which this subject has received in a textbook so far, and it is illustrated by a number of very beautiful and instructive plates. The third section gives the theory, as far as it has developed, of polarisation by metallic and by non-conducting particles, and a very full account of the variation of the specific rotation of gelatin, tannin, etc., with age and concentration. In the fourth section the validity of Lambert's and Beer's absorption formulæ for disperse systems is discussed, as well as the production of colour by the three factors which cause turbidity. The final section deals with the problem of expressing the refractive index of disperse systems in terms of the indices of the phases, their ratio and degree of dispersity.

The book is written throughout with that obvious and lively joy in the subject which is characteristic of all the author's works and sometimes tempts him into an almost epic breadth of treatment. The plan of the work—or, perhaps the nature of the subject—involves a considerable amount of repetition, some of which seems avoidable; thus it is not quite easy to see why opalescence should be treated quite separately from turbidity, and why Lord Rayleigh's formula should thus be discussed very amply in two places. A number of minor points, on which differences of opinion are possible, might be made, but they would exceed the scope of this review and do not materially affect the value of this pioneer work. The volume will have to have a place in every library of colloid chemistry, and the purchaser may find some consolation for the high price (which, no doubt, is partly justified by the expensive illustrations) in the thought that very little of it is spent on information already available in the other volumes on his shelves.

EMIL HATSCHEK

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech. ..	£23 10s. per ton.
Acid, Boric, Commercial—	
Cryst. ..	£45 per ton.
Powder..	£47 per ton.
Acid Hydrochloric ..	5s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw. ..	£21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric ..	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali..	£6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder ..	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime ..	£7 per ton, packages extra.
Borax, Commercial—	
Crystal ..	£25 per ton.
Powder..	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride ..	£5 17s. 6d. per ton d/d.
Copper Sulphate ..	£25 per ton.
Methylated Spirit 64 o.p.—	
Industrial ..	3s 1d.—3s. 5d. per gallon, according to quantity.
Mineralised ..	4s. 2d.—4s. 6d.
Nickel Sulphate .. / Nickel Ammon. Sulphate	£38 per ton d/d. Normal business.
Potash Caustic ..	£30—£33 per ton.
Potass. Bichromate ..	5¼d. per lb.
Potass. Chlorate..	3d.—4d. per lb.
Salammoniac ..	£32 per ton d/d.
Salt Cake..	£3 10s. per ton d/d.
Soda Caustic, solid ..	Spot lots: delivered, £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals ..	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98% ..	£24 per ton.
Sod. Bicarbonate ..	£10 10s. per ton, carr. paid.
Sod. Bichromate..	4½d. per lb.
Sod. Bisulphite Powder 60/62%..	£18—£19 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate ..	3d. per lb.
Sod. Nitrate refd. 96% ..	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Sulphide conc. 60/65	About £14 10s. per ton d/d.
Sod. Sulphide cryst. ..	£9 per ton d/d.
Sod Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden ..	5¼d.—1s. 4d. per lb., according to quality.
Antimony sulphide—	
Crimson ..	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic, Sulphide, Yellow	1s. 11d. per lb.
Barytes ..	£3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide ..	3s. 9d.—4s. per lb., according to quantity.
Carbon Bisulphide ..	£30—£33 per ton, according to quantity. Again dearer.
Carbon Black ..	7d.—7½d. per lb. ex wharf. Dearer.
Carbon Tetrachloride ..	£60—£65 per ton, according to quantity, drums extra. Again dearer.
Chromium Oxide, green..	1s. 3d. per lb.
Indiarubber Substitutes White and Dark ..	5d.—9½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black ..	£48 per ton, barrels free. Advanced.
Lead Hyposulphite ..	7½d. per lb.
Lithopone, 30% ..	£22 10s. per ton.
Mineral Rubber "Rubpron" ..	£16 5s. per ton f.o.r. London.
Sulphur ..	£10—£12 per ton, according to quality.
Sulphur Precip. B.P. ..	£56—£57 per ton, according to quantity.
Sulphur Chloride ..	4d. per lb., carboys extra. Dearer.
Thiocarbanilide ..	2s. 6d. per lb.
Vermilion, pale or deep ..	5s. 1d. per lb. dearer.
Zinc Sulphide ..	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

"Summer conditions" prevail in this as in most industries.

Acetate of Lime—	
Brown ..	£12 per ton.
Grey ..	£16 per ton.
Liquor ..	9d. per gall. 32° Tw.
Charcoal ..	£7 15s.—£9 5s. per ton, according to grade and locality. Market brisker.
Iron Liquor ..	1s. 7d. per gall. 32° Tw. 1s. 2d. ,, ,, 24° Tw.
Red Liquor ..	10d.—1s. per gall. 14/15° Tw.
Wood Creosote ..	2s. 9d. per gall. Unrefined.
Wood Naphtha—	
Miscible ..	4s. 10d. per gall. 60% O.P.
Solvent ..	5s. 3d. per gall. 40% O.P.
Wood Tar ..	£4 5s. per ton.
Brown Sugar of Lead ..	£43 per ton. Cheaper.

TAR PRODUCTS

Acid Carbolic—	
Crystals ..	6½d. per lb. Quiet.
Crude 60's ..	1s. 9d.—1s. 11d. per gall, according to district. Still quiet.
Acid Cresylic, 97/99 ..	2s.—2s. 1d. per gall. Demand fair.
Pale 95% ..	1s. 9d.—1s. 10. per gall.
Dark ..	1s. 9d.—2s. per gall. Quiet.
Anthracene Paste 40% ..	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained ..	7½d.—9d. per gall. Quiet.
Unstrained ..	6½d.—7½d. per gall.
Benzole—	
Crude 65's ..	7½d.—9d. per gall. ex works in tank wagons.
Benzole—	
Standard Motor ..	1s. 1½d.—1s. 3d. per gall. ex works in tank wagons.

Benzole—

Pure	.. 1s. 5½d.—1s. 7d. per gall. ex works in tank wagons.
Toluole 90% ..	.. 1s. 5d.—1s. 5½d. per gall. Small demand.
Pure ..	.. 1s. 8d.—2s. per gall. Small demand.
Xylol coml. ..	.. 2s. 3d. per gall.
Pure ..	.. 3s. 3d. per gall.

Creosote—

Cresylic 20/24%	.. 8½d. per gall. Not much business.
Middle Oil .. .. / Heavy Oil .. .. / Standard Specification	5d.—6½d. per gall., according to quality and district. Small export inquiry. Market quiet but fairly steady.

Naphtha

Solvent 90/160	.. 11d.—1s. 5d. per gall., according to district. Fair demand.
Solvent 90/100	.. 11d.—1s. 4d. per gall. Fair demand.

Naphthalene Crude—

Market dull. Not much export inquiry. Cheaper in Yorkshire than Lancashire.

Drained Creosote Salts £1—£6. Quiet.

Whizzed or hot pressed £7—£9 per ton.

Naphthalene—

Crystals and Flaked	.. £13—£16 per ton in Yorkshire and London respectively.
Pitch, medium soft	.. 55s. 60s. per ton f.a.s. for next season. Frequent inquiries.
Pyridine—90/160	.. 19s. per gall. Again dearer. Market firm.
Heavy ..	.. 12s.—12s. 6d. Little business.

INTERMEDIATES AND DYES

There has been a considerable falling off in business in Aniline Dyes. Orders are now being received for day to day requirements only. The outlook is not very promising.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% ..	1s. 7d. per lb.
Acid H.	.. 3s. 11d. per lb. 100% basis d/d.
Acid Naphthionic	.. 2s. 2d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech.	.. 1s. 1d. per lb. Improved demand.
Acid Sulphanilic	.. 9¼d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil ..	.. 7¾d.—8½d. per lb. naked at works.
Aniline Salts ..	.. 7¾d. 9d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base ..	.. 4s. per lb. 100% basis d/d.
Benzyl Chloride 95%	.. 1s. 1d. per lb.
p-Chlorphenol ..	.. 4s. 3d. per lb. d/d.
p-Chloraniline ..	.. 3s. per lb. 100% basis.
o-Cresol 19/31° C.	.. 4½d. per lb. Demand steady.
m-Cresol 98/100%	.. 2s. 1d. 2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	.. 2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline ..	.. 3s. per lb.
Dichloraniline S. Acid	.. 2s. 6d. per lb. 100% basis.
p-Dichlorbenzol .	.. £85 per ton.
Diethylaniline ..	.. 4s. 6d. per lb. d/d., packages extra, returnable.
Dimethylaniline ..	.. 2s. 3d. per lb. d/d. Drums extra.
Dinitrobenzene ..	.. 10d. per lb. naked at works.
Dinitrochlorbenzol	.. £84 10s. per ton d/d.
Dinitrotoluene—48/50° C.	8d.—9d. per lb. naked at works.
66/68° C.	1s. 2d. per lb. naked at works.
Diphenylamine ..	.. 2s. 10d. per lb. d/d.
Monochlorbenzol ..	.. £63 per ton.
*β*Naphthol ..	.. 1s. per lb. d/d.
*α*Naphthylamine	.. 1s. 4d. per lb. d/d.
*β*Naphthylamine	.. 4s. per lb. d/d.
m-Nitraniline ..	.. 4s. 3d. per lb. d/d.
p-Nitraniline ..	.. 2s. 3d. per lb. d/d.
Nitrobenzene ..	.. 5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol	.. 2s. 11d. per lb. 100% basis d/d.
Nitronaphthalene	.. 10½d. per lb. d/d.
p-Nitrophenol ..	.. 1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	.. 3s. 11d. per lb. d/d.
p-Phenylene Diamine	.. 10s. 2d. per lb. 100% basis d/d.
R. Salt	.. 2s. 5d. per lb. 100% basis d/d.
Sodium Naphthionate	.. 2s. 3d. per lb. 100% basis d/d.
o-Toluidine ..	.. 8½d. per lb.
p-Toluidine ..	.. 4s. 2d. per lb. naked at works.
m-Toluylene Diamine	.. 4s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	.. £47 per ton.
Acid, Acetyl Salicylic	.. 3s. 1d.—3s. 3d. per lb., according to quantity.
Acid, Benzoic B.P.	.. 3s. per lb.
Acid Boric B.P. ..	.. Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric ..	.. 19s.—21s. per lb.
Acid, Citric ..	.. 1s. 4½d.—1s. 5d. per lb., less 5% for ton lots. Market very weak.
Acid, Gallic ..	.. 3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst.	.. 6s. 9d. per lb. Resublimed quality 8s. per lb. Market firm; increasing demand.
Acid, Salicylic ..	.. 1s. 6d.—1s. 9d. per lb., according to quantity. Demand rather easier.
Acid, Tannic B.P.	.. 2s. 10d. per lb. Market quiet.
Acid, Tartaric ..	.. 1s. 1½d. per lb. less 5%.
Amidol	.. 9s. per lb. d/d.
Acetanilide ..	.. 2s. 1d.—2s. 3d. per lb. fc quantity. Demand slow.
Amidopyrin ..	.. 13s. 3d. per lb. Neglected. Stock low.
Ammon. Benzoate	.. 3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	.. 12s. 6d. per oz. for English make.
Barbitone	.. 15s.—15s. 6d. per lb. Quiet market.
Benzonaphthol ..	.. 5s. 3d. per lb. Small inquiry.
Bismuth Salts ..	.. Prices reduced by about 1s. 3d.—2s. 3d. per lb. on account of the fall in the price of the metal.
Bismuth Carbonate	.. 10s. 6d.—12s. 6d. per lb.
,, Citrate ..	.. 10s. 3d.—12s. 3d. ,,
,, Salicylate	.. 9s.—11s. ,,
,, Subnitrate	.. 8s. 8d.—10s. 8d. ,,
Borax B.P. ..	.. Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides	.. Market firm, and Continental prices fully maintained with upward tendency.
Ammonium ..	.. 1s. 6d.—1s. 9d. per lb.
Potassium .	.. 1s. 4d.—1s. 7d. per lb.
Sodium .	.. 1s. 5d.—1s. 8d. per lb.
Calcium Lactate	.. 1s. 5d.—1s. 9d., according to quantity. Fair demand and steady market.
Chloral Hydrate ..	.. 4s.—4s. 3d. per lb. Very firm and scarce.
Chloroform ..	.. 2s. per lb. for cwt. lots. Very steady
Creosote Carbonate	.. 6s. 6d. per lb. Little demand.
Formaldehyde ..	.. £59 per ton.
Glycerophosphates—	Fair business passing.
Calcium, soluble and citrate free ..	.. 7s. per lb.

Glycerophosphates—	
Iron	.. 8s. 9d. per lb.
Magnesium ..	.. 9s. per lb.
Potassium, 50%	.. 3s. 6d. per lb.
Sodium, 50% ..	.. 2s. 6d. ,,
Guaiacol Carbonate	.. 10s. 6d.—11s. 3d. per lb.
Hexamine ..	.. 3s. 6d. per lb. for English make —market steady.
Homatropine Hydrobromide	30s. per oz.
Hydrastine hydrochlor ..	English make offered, 120s. per oz.
Hypophosphites—	
Calcium ..	.. 3s. 6d. per lb., for 28-lb. lots.
Potassium ..	.. 4s. 1d. per lb.
Sodium ..	.. 4s. ,,
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 5d. per lb.
Magnesium Carbonate—	
Light Commercial	.. £36 per ton net.
Magnesium Oxide—	
Light Commercial	.. £75 per ton, less 2½%.
Heavy Commercial	.. £25 per ton, less 2½%. Price reduced.
Heavy Pure ..	.. 2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	.. 57s. 6d. per lb.
Synthetic ..	.. 26s.—31s. per lb., according to quantity. English make.
Mercurials ..	.. Market very quiet.
Red oxide ..	.. 5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	.. 3s. 6d.—3s. 7d. ,,
White precip. ..	.. 4s. 7d.—4s. 8d. ,,
Calomel ..	.. 3s. 11d.—4s. ,,
Methyl Salicylate	.. 1s. 10d.—2s. 1d. per lb. Keen competition.
Methyl Sulphonal	.. 26s. per lb.
Metol	.. 11s. per lb. British make.
Paraformaldehyde	.. 2s. 10½d.—3s. per lb. Not very active.
Paraldehyde ..	.. 1s. 5d.—1s. 6d. per lb. in free bottles and cases.
Phenacetin ..	.. 6s. per lb. Price and demand steady.
Phenazone .	.. 7s. 2d. per lb.
Phenolphthalein ..	.. 5s. 6d.—5s. 8d. per lb. in cwt. lots.
Potass. Bitartrate—	
99/100% (Cream of Tartar) ..	.. 88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate ..	.. 1s. 10d.—2s. 2d. per lb.
Potass. Iodide ..	.. 16s. 8d.—17s. 5d. per lb., according to quantity. Good steady demand.
Potass. Metabisulphite	.. 7½d. per lb., 1-cwt. kegs included. F.o.r. London.
Potass. Permanganate	.. 7¼d. per lb.
Quinine Sulphate	.. 2s. 3d.—2s. 4d. per oz., in 100 oz tins. Steady market.
Resorcin	.. 5s. 6d. per lb.
Saccharin ..	.. 63s. per lb., in 50-lb. lots.
Salol	.. 3s. 6d. per lb.
Silver Proteinate ..	.. 9s. 6d. per lb.
Sod. Benzoate, B.P.	.. 2s. 6d. per lb. Ample supplies. B.P. quality available.
Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity.
Sod. Hyposulphite—	
Photographic ..	.. £13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	.. 16s. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	.. 75s.—82s. 6d. per cwt., according to quantity. Quiet market.
Sod. Salicylate ..	.. Market rather easier. Powder 2s. 1d.—2s. 3d. per lb. Crystal at 2s. 3d.—2s. 5d. per lb. Flake 2s. 9d. per lb.
Sod. Sulphide—	
Pure recryst. ..	.. 10d.—1s. 2d. per lb.
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Sulphonal	.. 15s. per lb. Easier.
Thymol	.. 20s. per lb. nominal. Very scarce indeed.

PERFUMERY CHEMICALS

Australian ..	.. 21s. per lb.

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before Nov. 10th; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on Sept. 25th.

I.—Applications

Crowe and Mills. Precipitating and filtering. 20,832. Sept. 3.

Fothergill. Evaporators. 20,888. Sept. 4.

Heyl. Heating and distillation of liquids and solids, etc. 20,750. Sept. 3.

Synthetic Ammonia and Nitrates, Ltd. Carrying out catalytic reactions. 20,572. Sept. 1. (U.S. 1.9.23.)

I.—Complete Specifications Accepted

14,371 (1923). Fahim. Crushing-mills. (221,001.)

26,714 (1923). Shores, Towers, and United Alkali Co., Ltd. Means for closing, or sealing, glass or like containers, more especially adapted for use in the transport of chemicals. (221,107.)

26,918 (1923). Hunter. Settling or precipitation tanks. (221,109.)

29,996 (1923). Lake. (Furnace Engineering Co.). Pulverizers. (221,121.)

II.—Applications

Caspari. Distillation of bituminous substances. 20,704. Sept. 2. (Ger., 24.10.23.)

Freeman. Treating oil-bearing shales. 20,903. Sept. 4.

Heyl. 20,750. *See* I.

Holden. Manufacture of water-gas. 20,824, 20,825. Sept. 3.

Jones. Manufacture of combustible gas. 21,071. Sept. 6.

Melamid. Process of liquefying carbon. 21,019. Sept. 5. (Ger., 17.6.24.)

Sauer. 20,793. *See* XIX.

Sauer. 20,905. *See* XX.

Trumble. Producing gasoline from solid material. 20,697. Sept. 2.

II. Complete Specifications Accepted

14,493 (1923). Lamplough. Destructive distillation apparatus. (221,009.)

18,107 (1923). Trumble. Treating carbonaceous materials. (221,052.)

IV.—Application

Compagnie Nationale de Matières Colorantes et Manufactures de Produits Chimiques du Nord, Réunies, Etablissements Kuhlmann. 20,693. *See* XX.

IV.—Complete Specifications Accepted

14,489 (1923). Sokal (Kalle & Co.). *See* XX.

27,219 (1923). Meister, Lucius, und Bruning. Manufacture of acid azo-dyestuffs. (206,831.)

V.—Application

Textilpatentges. Improving vegetable fibres. 21,09[illegible] Sept. 6. (Ger., 8.9.23.)

V.—Complete Specification Accepted

13,769 (1923). Soc. Indus. pour l'Application de Breve[illegible] et Procédés. Treatment of hydrated celluloses to diminis[illegible] their absorptive capacity. (201,526.)

VI.—Applications

British Dyestuffs Corporation, Ltd., Blackshaw, Horsfa[illegible] and Lawrie. Dyeing etc. wool and fur. 21,086, 21,0[illegible] Sept. 6.

VII.—Applications

Crowe and Mills. Recovering cyanogen from soluti[illegible] 20,833. Sept. 3.

Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Appara[illegible] for synthetic production of ammonia. 20,689. Sept.[illegible] (Norway, 28.9.23.)

Phillipp and Sutherst. Manufacture of colloidal sulp[illegible] 20,998. Sept. 5.

Synthetic Ammonia and Nitrates, Ltd. Productio[illegible] nitric acid from ammonia. 21,066. Sept. 6. (U.S. 6.9.[illegible]

Synthetic Ammonia and Nitrates, Ltd. Produ[illegible] ammonium nitrate. 21,067. Sept. 6. (U.S., 6.9.23.)

VII.—Complete Specifications Accepted

14,295 (1923). Koritschoner and Hansgirg. Manufa[illegible] of pure alumina. (199,017.)

24,023 (1923). Metallbank und Metallurgische [illegible] Furnaces for burning sulphur. (210,734.)

VIII.—Applications

Dynamidon Werk Engelhorn & Co., Ges. Productio[illegible] fireproof magnesite. 21,105. Sept. 6. (Ger., 14.9.23[illegible]

Hancock. Manufacture of pottery. 20,557. Sept. [illegible]

VIII.—Complete Specification Accepted

26,714 (1923). Shores, Towers, and United Alkali Co., Ltd. *See* I.

IX.—Complete Specification Accepted

14,872 (1923). Schmidt and Hahnle. Producing hydraulic cement and artificial stones. (221,017.)

X.—Applications

Coley. Manufacture of zinc. 20,920. Sept. 4.

Debuigne. Production of carbon-free metals of low silicon content. 20,621. Sept. 1. (Ger., 31.8.23.)

Poldihütte. Steel alloy. 21,022. Sept. 5. (Czecho-Slovakia, 5.9.23.)

X.—Complete Specification Accepted

22,565 (1923). Mond (Goldschmidt Akt.-Ges.). Production of aluminium alloys. (221,082.)

XI.—Applications

Burgess Battery Co. Dry batteries. 20,606. Sept. 1. (U.S., 1.9.23.)

Soc. Anon. Le Carbone. Electric batteries. 21,015. Sept. 5. (Fr., 12.7.24.)

XI.—Complete Specification Accepted

25,279 (1923). Casale. Apparatus for the electrolysis of water. (221,102.)

XII.—Complete Specifications Accepted

14,363 (1923). Technical Research Works, Ltd., and Lush. Preparation and reactivation of metallic catalysts used in the hydrogenation of oils etc. (221,000.)

16,164 (1923). Meulen. Vulcanising oils or fats. (201,531.)

XIII.—Applications

Heyl. Mineral pigments. 20,749. Sept. 3.

Latex Developments, Ltd., and Russell. Waterproof paints. 20,786. Sept. 3.

XIII.—Complete Specifications Accepted

13,753 (1923). Wade (Karpen and Bros.). Manufacture phenolic condensation products. (220,985.)

18,929 (1923). Pollak. Manufacture of condensation products from formaldehyde and urea, thio-urea, or their derivatives. (201,906.)

IV.—Applications

Bamber. Treatment of rubber. 20,802. Sept. 3.

Clute. Curing rubber. 20,711. Sept. 2. (U.S., 18.9.23.)

V.—Complete Specification Accepted

[illegible]6,161 (1923). Meulen. *See* XII.

[illegible]—Applications

Marris, Ross, and Walker and Sons. Process of removing [illegible]ir from skins. 20,556. Sept. 1.

Rack. Manufacture of liquid glue. 21,042. Sept. 6.

[illegible]—Complete Specification Accepted

[illegible]2 (1923). Lloyd, Pickard, and British Leather [illegible]facturers' Research Association. Soaking-liquors for [illegible] hides and the like. (221,058.)

[illegible]III.—Application

Bendixen, Harrison, and Stapley. Apparatus for propa[illegible] pure cultures of bacteria, yeast, etc. 20,759. Sept. 3.

[illegible]—Applications

[illegible]bs and Lane. Preserving etc. meat. 21,089. Sept. 6.

[illegible]les and McDougall. Manufacture of insecticides etc. [illegible] Sept. 2.

[illegible]er. Activated carbon for purification of water etc. [illegible] Sept. 3.

[illegible]—Applications

[illegible]ompagnie de Béthune. Production of ethyl-sulphuric [illegible]id. 21,032. Sept. 5. (Fr., 7.9.23.)

Compagnie Nationale de Matières Colorantes et Manufac[illegible]res de Produits Chimiques du Nord, Réunies, Etablisse[illegible]ents Kuhlmann. Process for manufacture of perylene. 20,693. Sept. 2. (Fr., 20.12.23.)

Sauer. Activated carbon for medicinal purposes. 20,905. Sept. 4.

XX. Complete Specifications Accepted

14,189 (1923). Sokal (Kalle and Co.). Producing perylenetetracarboxylic acids or their monoimides. (221,008.)

[illegible]5 (1924). Mendel Akt.-Ges., and Wolffenstein. Producing halogen albumin compounds. (213,536.)

XXI.—Complete Specification Accepted

18,665 (1923). Lilienfeld and Jahoda. Fluorescent screens for X-rays. (201,519.)

XXII.—Application

Tagliabue. Manufacture of explosives. 20,936. Sept. 4.

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number: *Argentina*: Interior paints (299). *Canada*: Soap (280). *Egypt*: Paints, linseed oil (297). *France*: Oils, fats for soap-making, chemical manures, nitrate of soda, sulphate of ammonia (284). *Greece*: Steel tubes (287). *Japan*: Dyestuffs (B.X./1215). *Poland*: Chemicals rubber and surgical goods (295). *South Africa*: Paraffin oil (B.X./1222); Disinfectant fluid (B.X./1226); Red oxide paint in paste (B.X./1225). *Uruguay*: Camphor (300); Iron (A.X./1295).

Trade Information

Pyrex Glassware is now being made in England by James A. Jobling & Co., Ltd., at the Wear Flint Glass Works, Sunderland. Pyrex glass is a borosilicate glass which resists sudden cooling and is claimed to be superior to other glasses in its resistance to water, acid, ammonia and phosphoric acid, and equal to other high-grade glasses in resistance to alkali carbonates and caustic alkalis. The coefficient of linear expansion is very low, 0·0000032, compared with 0·0000092 for lead glass. All the usual forms of laboratory glassware are made in Pyrex glass, which is also used for making ovenware.

Sutcliffe Bros. & Bryce, Ltd., Globe Works, Hyde, have acquired the old-established boiler-covering business of W. J. Hockey & Co., of Cardiff. Mr. W. J. Hockey has joined the Board of Sutcliffe Bros. & Bryce, Ltd., and will manage this branch of the business as heretofore. The acquisition of these works and offices will afford Sutcliffe Bros. & Bryce, Ltd., greater facilities for carrying out their South Wales and District contracts than they have enjoyed hitherto. The address of the new branch will be Sutcliffe Bros. & Bryce, Ltd., W. J. Hockey & Co., Branch, Hodges Row, Docks, Cardiff.

Science and the Baker

Baking is a process that ultimately concerns everyone, but scientific control is, unfortunately, not yet a feature of standard practice. An interesting attempt is now being made to establish the science of baking by the *Arkady Review*. Although this new publication is really devoted to the merits of "Arkady," a yeast food for which valuable qualities are claimed by its makers, the British Arkady Co., Ltd., Manchester, advertising matter is not too conspicuous, and articles are given explaining, in simple language, common words such as salts and sugars, the use of the thermometer, malt and malting, yeasts and starch, science and bread-making. Mention must be made of the excellent photomicrographs reproduced in each issue. The inclusion of educational matter deserves commendation and will, it is hoped, make the baking industry realise the power of science and the invaluable help it can give. The editors of the *Arkady Review* are to be congratulated on their attempt to bridge the gap between the technologist and the working baker. The inclusion, in the third number, of a supplement containing a lecture on the Colloid Chemistry of Bread-making, by Mr. R. Whymper, is a feature that augurs well for the new *Review*.

Gas Undertakings in Great Britain

Part I of the Return relating to Authorised Gas Undertakings in Great Britain for the year 1923 (H.M. Stationery Office; price 5s. net) has been issued by the Board of Trade. This part contains particulars of the manufacture and supply of gas by 790 undertakings. Finance and the prices charged for gas will be dealt with in Part II.

The quantity of gas made in Great Britain in the year 1923 by these undertakings was 259,850

million cb. ft., of which nearly 84 per cent. was coal gas and nearly 15 per cent. water gas. Excluding the gas consumed at gasworks, 241,627 million cb. ft. was sold, compared with 232,603 million cb. ft. in 1922 and 229,077 in 1921. The residual products in 1923 included 11,098,000 tons of coke and breeze and 181,963,000 gallons of tar. These consumption figures, combined with the following figures of number of consumers and length of mains, illustrate the continued extension of the use of gas :—

	1923	1922	1921
Number of consumers—			
Prepayment	4,231,243	4,137,009	4,071,220
Ordinary	3,579,107	3,535,137	3,488,090
Length of mains, in miles	40,981¼	40,231½	39,547¾

The Return gives particulars of the make of gas materials used, quantities of residuals made, numbers of consumers, etc., for each of the 790 undertakings. For concerns authorised to charge for heat units supplied, the quantities of gas made and sold are shown in therms as well as in cubic feet.

PUBLICATIONS RECEIVED

ANILINE AND ITS DERIVATIVES. By P. H. Groggins. Pp. vii+256. London: Chapman and Hall, Ltd., 1924. Price 18s.

MODERN CEREAL CHEMISTRY. By D. W. Kent-Jones, B.Sc. With a foreword by W. Jago, F.I.C. Pp. ix+324. Liverpool: The Northern Publishing Co., Ltd., 1924.

COAL CARBONIZATION. By H. C. Porter, M.S., Ph.D., American Chemical Society Monograph Series. Pp. 442. New York: The Chemical Catalog Co., Inc., 1924. Price $6·00.

THE STRUCTURE OF CRYSTALS. By R. W. G. Wyckoff. American Chemical Society Monograph Series. Pp. 462. New York: The Chemical Catalog Co., Inc., 1924.

REPORT OF THE ECONOMIC CONDITIONS IN FRANCE. By J. R. Cahill. Department of Overseas Trade. Pp. 221. H. M. Stationery Office, 1924. Price 6s.

THE NATIONAL PHYSICAL LABORATORY REPORT FOR THE YEAR 1923. Department of Scientific and Industrial Research. Pp. 228. Price 13s. 6d.

THE RUBBER MANUFACTURERS' HANDBOOK. TABLES AND FORMULÆ. By W. G. Pinkney and P. Watkins. Pp. 89. London: The Rubber Age, 1924. Price 12s. 6d.

THE NEW THEORIES OF MATTER AND THE ATOM. By A. Berthoud. Translated by Eden and Cedar Paul. Pp. 259. London: G. Allen and Unwin, Ltd., 1924. Price 10s. 6d.

THE BOOK OF RECEIPTS. By E. W. Lucas and H. B. Stevens. Twelfth edition. Pp. 473. London: J. and A. Churchill, 1924. Price 10s. 6d.

A CATALOGUE OF OLD AND MODERN MEDICAL AND SCIENTIFIC BOOKS. No. 25. Pp. 12. London: Bligh and Co., 1924

—Complete Sy... (1923).

SYLLABUS OF CLASSES AT SIR JOHN CASS TECHNICAL INSTITUTE, ... STREET, ALDGATE, E.C. Session 1924-25.

... azo-dyes Pp. ...

PROSPECTUS OF UNIVERSITY COURSES IN THE MUNICIPAL SCHOOL OF TECHNOLOGY, UNIVERSITY OF MANCHESTER, FACULTY OF TECHNOLOGY. Session 1924-25. Pp. 229.

L'ECONOMISTE ROUMAIN. BULLETIN MENSUEL DE L'INSTITUT ECONOMIQUE ROUMAIN ET DE L'ASSOCIATIO DES BANQUES ROUMAINES. No I. Pp. 24. Bucarest: 1924.

PUBLICATIONS OF THE DEPARTMENT OF THE INTERIOR, BUREAU OF MINES, WASHINGTON: GOVERNMENT PRINTING OFFICE, 1924:—

SILVER IN CHLORIDE VOLATILIZATION. By C. M. Bonton, W. C. Riddell and L. H. Duschak. Technical Paper 317. Pp. iv.+56. Price 10 cents.

TESTS OF MARINE BOILERS. By H. Kreisinger, J. Blizard, A. R. Mumford, B. J. Cross, W. R. Argyle and R. A. Sherman. Bulletin 214. Pp. xiv.+303. Price 55 cents.

PUBLICATION OF THE DEPARTMENT OF THE INTERIOR, U.S. GEOLOGICAL SURVEY, WASHINGTON: GOVERNMENT PRINTING OFFICE, 1924:—

PLATINUM AND ALLIED METALS IN 1923. By J. M. Hill, No. 1: 2. Pp. 9—22. Mineral Resources of the United States, 1923. Part I.

UNITED STATES GOVERNMENT MASTER SPECIFICATION FOR OLIVE DRAB PAINT (SEMIPASTE AND READY-MIXED). Circular No. 165. Department of Commerce, Bureau of Standards. Federal Specifications Board Specification No. 137. Pp. 11. Washington: Government Printing Office, 1924. Price 5 cents.

WEIGHTS AND MEASURES, DEPARTMENT OF COMMERCE, BUREAU OF STANDARDS, SIXTEENTH ANNUAL CONFERENCE OF REPRESENTATIVES FROM VARIOUS STATES HELD AT THE BUREAU OF STANDARDS IN MAY, 1923. MISCELLANEOUS PUBLICATIONS No. 55. Pp. 153. Washington: Government Printing Office, 1924. Price 30 cents.

MASLAMA AL-MAJRĪTĪ AND THE RUTBATU'L-HAKĪM. By E. J. Holmyard. Reprint from Isis, No. 18, Vol. VI. (3), 1924. Pp. 293—305. Bruxelles: Société Anonyme M. Weissenbruch, 1924.

A REFERENCE LIST OF BIBLIOGRAPHIES, CHEMISTRY, CHEMICAL TECHNOLOGY AND CHEMICAL ENGINEERING PUBLISHED SINCE 1900. Compiled by J. A. Sohon and W. L. Schaaf. Pp. x+100. New York: The H. W. Wilson Co., 1924. Price $6.

TAGESFRAGEN. Edited by Prof. Küster. Stuttgart. Biochemische Wissenschaftliche Verlagsgesellschaft m.b.H., 1924:—

(1) VOM CHEMISCHEN WESEN UND DER BIOLOGISCHEN BEDEUTUNG DES EIWEISS. By Prof. W. Küster. Part III. Pp. 18.

(2) DIE BEZIEHUNGEN ZWISCHEN PFLANZE UND TIER IM LICHTE DER CHEMIE. By Prof. Tschirch. Part II. Pp. 22.

DIE FERMENTE UND IHRE WIRKUNGEN. By Prof. C. Oppenheimer, with a section on Physical Chemistry and Kinetics by Dr. R. Kuhn. Lieferung II. Pp. 161—320. Leipzig: Georg Thieme, 1924. Price $1·90.

DIAGNOSTISCHE UND THERAPEUTISCHE IRRTÜMER UND DEREN VERHÜTUNG. INNERE MEDIZIN. By Prof. J. Schwalbe. Part 15. Vergiftungen. By Prof. H. Zangger. Pp. 226. Leipzig: Georg Thieme, 1924. Price $1·45.

JOURNAL of THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council of Pure and Applied Chemistry
which consists of Representatives from
The Chemical Society, the Society of Chemical Industry, the Association of British Chemical Manufacturers, the Institute of Chemistry, the Society of Public Analysts, the Faraday Society, the Institute of Brewing, the Society of Dyers and Colourists, the Society of Glass Technology, the Iron and Steel Institute, the Ceramic Society, the Institution of Gas Engineers, the Society of Leather Trade Chemists, the Royal Photographic Society, the Mineralogical Society, the Biochemical Society, the Institute of Metals, and the Royal Agricultural Society.

VOL. 43 NEW SERIES — LONDON, SEPTEMBER 26, 1924 — NO. 39

EDITORIAL

NEARLY thirty years ago Röntgen discovered X-rays; twelve years ago Laue, Friedrich and Knipping used crystals as diffraction gratings to produce interference effects of X-rays and Sir William Bragg and Professor W. L. Bragg devised the method of interpreting the structure of crystals and the position of the atoms in them by measurement of the angles of incidence of X-rays which showed maxima and minima of interference in the reflected rays. The photographic recording of these is largely due to the skill of Moseley, Siegbahn and de Broglie. During these last twelve years our knowledge of crystals and how they are built up from molecules, atoms, ions, protons and electrons has been increased very considerably, and Sir William Bragg has been responsible for a large part of this extension of knowledge. Men are continually struggling to explain highly-complicated phenomena, some of which are imperfectly known, by simple signs capable of being expressed on a printed page. Popular journals expound to a non-mathematical body of readers Einstein's theory of a four-dimension system which seems to involve at least some algebra and conic sections in its elementary essentials. Chemists are continually trying to express by the fewest possible printed symbols the interaction of electrical forces of extreme complexity, so complex that our most skilful mathematicians cannot calculate the combined effect of them. The formulæ and equations of the chemists have been singularly ingenious and useful, so useful that, to many, they appear to be accurate diagrams of the changing facts. The capital letters of the alphabet and a few short straight lines have enabled us to express a sort of approximation to the truth in a very convenient way. The addition of a plus and a minus sign and a few dotted lines enables a little higher degree of complexity to be indicated. But it is like trying to represent a football match, a battle or the flux of European politics by means of a few diagrams. Sir William Bragg's address on the Analysis of Crystal Structure by X-rays shows how impossible it is to draw rigid distinctions between unit cells, atoms and ions, between agglomeration, cohesion, chemical attraction, electrostatic attraction and so on. We get on to the borders of metaphysics and logic, and the discussion of some of these topics is akin to an investigation of the relations between the different parts of a Highland tartan; we may easily fix the smallest unit which enables us to describe the Mackenzie tartan or the Hunting Stuart but there is no obvious boundary to this unit. If the tartan were in three dimensions we should have an exact parallel to the crystal. So, too, in our representations of molecules we try and make a few brackets and lines such as $Be_4O(CO_2CH_3)_6$ represent the combined effect of some 47 different atoms most of which include several electrons each with attractions, repulsions, orbits and eccentricities of its own. Bragg and Morgan last year showed us that this beryllium compound is built up round one central oxygen atom, four beryllium atoms are tetrahedrally connected to it by a set of electrical attractions, with six acetate groups arranged symmetically round the edges of the imaginary tetrahedron. We have here a further degree of approximation to the truth, but when we consider how little we know of the electron, whether we are to consider it as fixed in space, as revolving round a nucleus, or a couple of nuclei, whether electricity in these minute quantities and at such minute distances obeys the law of inverse squares and so on, we know that such a description is only an approximation. Nevertheless, each further degree of approximation takes us nearer and nearer to the truth. A proper understanding of planes of symmetry and spatial distribution of atoms and other disturbing entities is essential to modern work, and Sir William Bragg's able treatment of these makes an important address.

* * *

We published on August 8 an account of a rapid method of drying glue and gelatin adopted in the laboratory of Messrs. Scheidemandel. Our esteemed contemporary *The Chemical Age* has mildly suggested in the past that we should not have embarked on the stormy voyage of a business career; one of the reasons we did this was the belief that scientific information could be more promptly and accurately dispensed by the Society in weekly numbers than by any other method. *The Chemical Age* in its issue of September 20 gives an account, which it acknowledges is taken from *Industrial and Engineering Chemistry*, of a method of preparing lime and gelatin in pearls by squeezing lime or gelatin through a set of fine openings. *Industrial and Engineering Chemistry* has been engaged, we think, in playing a practical joke on its readers. There is a German word "Leim" which means glue or gelatin, and we suspect that this word was found in the original

memoir from which the legend of lime in pearl form originated. The glue pearls, a sample of which lies before us, should prove useful. Every father, whose family includes a few young boys, knows the disadvantages of glue as usually sold; he may break it with a hammer but the bits fly all over the carpet; the large lumps take so long to melt properly that the church bell rings before the mending can be commenced; Milton, or someone else, says that the worst of the amateur carver is that the gravy so seldom matches the wallpaper: the worst of the amateur joiner is that the glue so seldom matches the linoleum. Pearls of glue in the house should prove a well-spring of joy; we wish we knew where they could be purchased.

* * *

A certain amount of discussion goes on in the daily press and over the walnuts and wine which still adorn the tables of our wealthier acquaintances, as to the possibility of opening the Wembley Exhibition again next year. In spite of a wet summer, Wembley has always been well attended, and no one has visited the Exhibition without wishing to go again many times. We do not know whether grown-up people or children have derived the most pleasure and benefit. As an outward and visible sign of the British Empire it has been unique; its political consequences are bound to be of the utmost importance, for our Empire is held together very largely by common sentiment and common interest; it is essential in these circumstances that the more we all know of its far-flung parts the more we shall appreciate the good features, innumerable as they are, of the Empire. Let us look on some of these and rejoice, *video meliora proboque*. From the point of view of trade and commerce, we imagine that a considerable number of firms have sold their wares so fast that their delivery organisation has been strained to its uttermost. We have given long accounts in this journal of the chemical exhibits and still have additional notes to publish. The chemical exhibit has been conspicuously successful; it has brought home to chemists and to the general public the enormous importance of chemistry in very many industries; it has demonstrated to the world a fact, which required demonstration, that British chemistry is first-class. It has evoked Chemistry in the Twentieth Century, which has sold in thousands and a set of pamphlets which have been sold in tens of thousands. As to the finances of the Exhibition, these are not known to us, but it is reported that about fifteen or sixteen million visits have been recorded at the turnstiles; this is less than was originally expected by the sanguine promoters, so it is probable a loss has been incurred. The chemical exhibit, valuable as it has been both from a scientific and industrial point of view, will be very valuable next year if the Exhibition can be again opened then. It has by no means outlived its usefulness; its lessons are not yet fully appreciated. We hope that some means may be found of opening the Exhibition again next year, and we are sanguine enough to think that next year might easily provide a considerable profit as a set-off against this year's expected deficit.

THE ANALYSIS OF CRYSTAL STRUCTURE BY X-RAYS *

By SIR W. H. BRAGG, K.B.E., D.Sc., F.R.S.

In this address I propose to consider the new methods of analysing the structure of materials by means of X-rays, considering especially the stages by which they move towards their objective. It is convenient to recognise three such stages, of which the first comprises the simplest and most direct measurements and the last the most indirect and complex.

The fundamental measurement of the method is the angle at which rays of a given wave-length are reflected by a set of planes within the crystal. The planes of a "set" are all exactly like one another: an imaginary observer within the crystal could not tell by any change in his surroundings that he had been moved from one plane to another. Sometimes there is no reflection of the first order from a set so defined, because the planes may be interleaved by other planes so spaced and of such strength as to annul the true reflection; but this can always be allowed for. When the wave-length of the X-rays is known, the angular measurement can be used to find the spacing of the set of planes, and in this way a linear dimension of the crystal is measured. The spacing is the distance between any plane and its nearest like neighbour on either side. If the spacings of three different sets of planes are found, the volume of the unit cell is found. The crystal unit cell is bounded by six faces, each set of planes furnishing a pair. The pair consists of two neighbouring planes of the set. The cell may have a great variety of forms, but has always the same volume. The specific gravity of the substance being known, it is possible to find the number of atoms of various kinds which the cell contains: the proportion of the various kinds is necessarily the same as in the molecule of the substance. The cell is in practice found always to contain a small integral number of molecules, one, two, three, or four, rarely more. This assemblage of molecules is fully representative of the crystal; by the mere repetition of the cell, without the addition of any new features, the crystal with all its properties is produced.

There are, therefore, three types of assemblage. The simplest is that of the single atom, as in helium in the gaseous state, in which the behaviour of every atom is on the whole the same as the behaviour of any other. The next is that of the molecule, the smallest portion of a liquid or gas which has all the properties of the whole: and lastly, the crystal unit, the smallest portion of a crystal (really the simplest form of a solid substance) which has all the properties of the crystal. There are atoms of silicon and of oxygen: there is a molecule of silicon dioxide, and a crystal unit of quartz containing three molecules of silicon dioxide. The separate atoms of silicon and oxygen are not silicon dioxide, of course: in the same way the molecule of silicon

* **Presidential Address before Section A (Mathematical and Physical Science) of the British Association, Toronto.**

dioxide is not quartz; the crystal unit consisting of three molecules arranged in a particular way *is* quartz.

The final aim of the X-ray analysis of crystal is to determine the arrangement of the atoms and the molecules in the crystal unit, and to account for the properties of the crystal in terms of that arrangement.

The first step is the determination of the dimensions of the crystal unit cell: any one of the possible ways in which the cell can be drawn will do. When this has been completed it is a simple calculation in geometry to find the distance between any atom and any other atom in the crystal of like kind and condition, or, in other words, the distance an observer would have to travel from any point within the crystal to any other point from which the outlook would be exactly the same and would be similarly oriented. This is the only measurement which the X-rays make directly: any other measurement of distance is made indirectly, by aid of some additional physical or chemical reasoning. It is not possible by direct X-ray measurement to determine the distance between any two points—atom centres, for example—within the same cell.

Let us take an example. The crystal unit of naphthalene has the dimensions defined in the usual way by the statement:—

$$a=8{\cdot}34\text{Å} \quad b=6{\cdot}05\text{Å} \quad c=8{\cdot}69\text{Å}$$
$$\beta=122^\circ\ 49' \quad \alpha=\gamma=90^\circ.$$

It contains two molecules: an integral number, as always. These facts are given directly by the X-ray measurements. But there is no direct determination of the distance between any carbon atom and any other carbon atom contained within the same cell: the measurements given are those of the distances between any atom and the nearest neighbours, in three principal directions, which are exactly like itself, these distances being the lengths of the edge of the cell. There is not even a measurement of the distance between the two molecules in the same cell, because they are not similarly oriented. In fact, there is no clear meaning in the term "distance" in this case, just as we cannot state the distance between an object and its image in a mirror, unless the object is a point of no dimensions. If the molecule of naphthalene has a centre of symmetry, as is indeed indicated during the development of the results of the X-ray analysis, it is possible to state the distance between the centres of symmetry of the two molecules in the same cell, but this does not define the distance between any atom in one of the two molecules and any atom in the other. All such distances, if they are to be defined and measured, can only be found by the aid of fresh considerations.

Or again, let us take the case of rock-salt. The crystal unit cell of rock-salt contains one molecule: one form of the cell has for its eight corners the six middle points of the faces of a certain cube (edge=5·62 A.U.) and two of the opposite ends of any diagonal of the cube. The so-called face-centred cube is four times as large as the cell, and contains four molecules. The dimensions of the cell are determined directly by the X-rays, which measure the distance between each of the three pairs of parallel faces that contain it. The cell may be placed so that each corner of it is associated in the same way with a molecule of sodium, let us say: and, of course, the knowledge of the dimensions of the cell is equivalent to a knowledge of the distance between any two sodium atoms in the crystal, which atoms are all alike in every respect. But we have no direct measurement by the X-ray methods of the distance between a sodium and a chlorine atom. We infer that the chlorine atom lies at the centre of the sodium cell, or *vice versâ*, from considerations of symmetry. Crystallographic observations of the exterior form of the cell assign to the crystal the fullest symmetry that a crystal can possess. If the cell that has been described is to contain the elements of such full symmetry, the chlorine atom must lie at the centre of it. It cannot lie anywhere else, for every cell would contain a chlorine atom similarly placed. There would then be unique directions in the crystal; that is to say, polarities. Moreover, both the sodium and the chlorine atoms must themselves contain every symmetry of the highest class: the full tale of planes of symmetry, axes of rotation, and so on. They both have centres, and we can state the distance between a chlorine atom and a sodium atom because we can state it as between centre and centre, and put it equal to half the distance between two sodium atoms on either side of the chlorine. The structure of sodium chloride is then determined completely.

It may possibly be a difficulty that the cell so described does not at first appear to have all the symmetries of the rock-salt cube, but it is to be remembered that we are to expect the full display of symmetries only when the cell has been repeated indefinitely in all directions. We may take a simple case, as follows:—

FIG. 1

Suppose sodium and chlorine atoms were to be arranged in a line as in the figure, just as they are in any of the three principal directions in the crystal. A plane of symmetry perpendicular to the line of atoms indefinitely prolonged may be drawn through the centre of any atom. The unit cell is one molecule: one chlorine and one sodium. The unit by itself has not this symmetry, but the repetition of the same molecule in either direction on either side provides the symmetry. Moreover, each sodium and each chlorine must itself have a plane of symmetry, and the planes are equally spaced. We can state the distance between a sodium and a chlorine atom as half the distance between two sodiums.

Let us take one more instance, the diamond. The crystal unit cell contains two atoms of carbon: as in the case of rock-salt, it may be so chosen that, of its eight corners, six are the middle point of the faces of a certain cube and two are the ends of any diagonal of the cube. The sides of this cell are

determined by the X-rays, and are all equal to 2·52 A.U. This is the distance between any carbon atom and the nearest carbon atom which is exactly like itself. The distance between the two carbon atoms in the same cell is not measured directly, but can be inferred after it has been defined. This we are able to do because the carbon atom is tetrahedral; a tetrahedron has a centre, and we can state the distance between the centres of two tetrahedra, no matter how the tetrahedra are oriented. We know that the carbon atom, as built into the crystal, is tetrahedral, because the X-ray observations show that four trigonal axes meet in it. The two atoms in the cell are oriented differently; one may be said to be the image of the other, if translation shifts are ignored, in each of the faces of the cube. Considerations of symmetry or X-ray observations show that the centre of an atom of the one orientation lies at the centre of a tetrahedron formed by four atoms of the other orientation. The edge of this tetrahedron is the edge of the unit cell, and its length is 2·52 A.U. It may then be calculated that the distance between the one atom and the others, its nearest neighbours, is 1·54 A.U. We may call this distance the diameter of the carbon atom, but we must remember our original definition of the meaning of the term. Thus the 2·52 A.U. is the result of a direct unaided X-ray measurement, but the 1·54 A.U. is not, and has no meaning except after special definition.

Only such distances between atoms as can be calculated from the dimensions of the unit cell can be measured directly and without qualification. The determination of these distances may be looked on as the result of the *first stage* of the analysis by X-rays.

We now come to a *second stage*. It is possible to make other statements of the relative positions of atoms and molecules which, though less complete and informative than those of distances, and their orientations, are necessary to the solution of the crystal structure problem. These also are deduced by means of the X-ray methods.

It often occurs that the atoms or molecules in one cell can be divided into two portions which are the reflections of one another across some plane, or can be brought to be the reflection of each other by a shift parallel to the plane. In that case the orientation of the plane and the amount of the shift can be stated definitely, the former by inspection of the crystal or by X-ray observations, the latter by X-ray observations alone. So also it may happen that the atoms or molecules in the same cell may be divided into portions which can be made to coincide with each other by a rotation round some axis with or without a shift parallel to that axis. The direction of the axis can be found by inspection of the crystal or by X-ray observations; the amount of the shift can be found by X-ray observations alone.

In these cases the distances that are found by the X-ray method are all that can be stated without special definition. It is not possible to state the distance between an object and its image in a mirror, if the object has any extension in space; but it is possible to state the magnitude of a shift.

Measurements of this sort constitute a characteristic feature of the X-ray analysis, for which reason I would like to discuss them briefly.

We know that it is possible to separate crystals into thirty-two classes, according to the kind of external symmetry which they display. As we have hitherto been unable to look into the interior of the crystal, we have been obliged to be content with this imperfect classification by outer appearance.* It has been shown, however, that there is a classification by inner arrangement which is perfect and includes the other. It is beyond the limits of ordinary vision: out of the range of the lens and the goniometer. The interior arrangements of the crystal, of which the outer form is one consequence, are so varied as to furnish 230 different modes. With very few exceptions the X-rays now allow us to carry the classification to this higher degree. If the modes are grouped according to the external features of the crystals that follow them, we come to the well-known thirty-two classes, there being several modes in every class. I may be permitted to illustrate this important point by examples, although it is familiar to those who have studied crystallography. Let us consider first a two-dimensional example, which is much easier to describe than the three-dimensional actuality, and contains all the essential ideas.

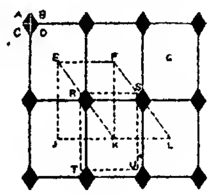

Fig. 2

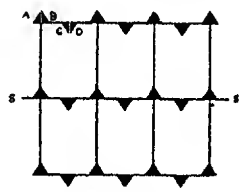

Fig. 3

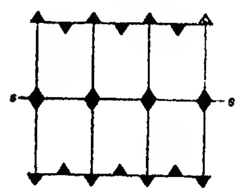

Fig. 3A

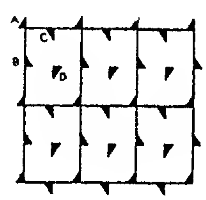

Fig. 4

Consider an arrangement of figures in a plane which displays symmetry across two planes at right angles to one another. Such arrangement may be exhibited diagrammatically, as in Fig. 2. The unit cell may be drawn in various ways, EFKJ, EFLK, RSUT, and so on. The cell contains, however it is drawn, either a whole diamond or enough parts to make up a whole diamond. Each diamond can be divided into four parts: B and D are the reflections of A and C across a plane; C and D are the reflection of A and B across a plane at right angles to the first plane. Unless the diamond, the content of one cell, could be divided in this way there could not be the

double symmetry. But, granted this division into four portions, it is not necessary that the four should be arranged as in the figure in order that the double symmetry may be obtained. There are two alternatives (Figs. 3 and 4).

In Fig. 3 the lower half of each diamond—that is to say, the portions C and D—are shifted, whether to right or to left is immaterial, by an amount equal to one-half of one side of the cell EFKJ. The symmetry about a vertical line in the plane of the paper is obviously retained. It is not so obvious that there is still any symmetry about the horizontal line until we realise that we mean only "observable symmetry": that which is to be seen in the outer form of the indefinitely extended figure, corresponding to the crystal. Clearly, the whole figure will present the same appearance from below as from above. In fact, we can see that as a whole the lower part of the figure is symmetrical with the upper part by imagining the upper and the lower to be further shifted relatively as in Fig. 3A: the two parts sliding on one another along the line SS. The two parts are then the image of each other across SS in the full sense of the word.

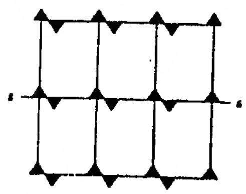

Fig. 5

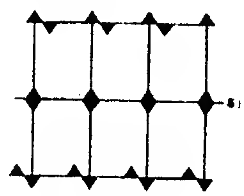

Fig. 5A

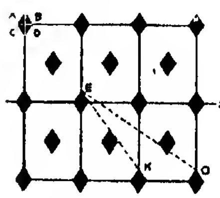

Fig. 6

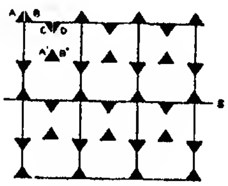

Fig. 6A

From Fig. 2A we may also realise that the amount of the original shift must be equal to one half of EF: no other shift will give the symmetry which Fig. 3A shows. In Figs. 5 and 5A a different shift has been given, and the failure is clear.

In Fig. 4 not only are C and D shifted parallel to the horizontal line, but also B and D are shifted parallel to the vertical; this time the amount of shift is one-half of the side EJ.

The three modes of Figs. 2, 3 and 4 all lead to the same external symmetry. There is one more which is based, as we should say, on a different lattice and is symmetrical, like the others, about two lines at right angles to each other. It is shown in Fig. 6. There are no variations of Fig. 6, as of Fig. 2, to be obtained by the introduction of shifts. If in Fig. 6 we shift C and D relatively to A and B, as we did in Fig. 3A, we find that they can now be described as the direct reflection of A′B′ into CD and of A′C into B′D, and the mode of Fig. 6A is the same as that of Fig. 6.

There are therefore four *modes* in one *class*: four varieties of internal arrangement which all lead to the same external appearance of symmetry.

Our example is two-dimensional, and the crystal has three dimensions. But there are no new ideas to be added: it is only the numbers of symmetries, modes, and classes that are increased. If, for example, we continue the study of the modes of arrangement that lead to an external symmetry of reflection across two planes at right angles to each other, we find that there are four lattices instead of two, and twenty-two modes instead of four. The class containing crystals that possesses this particular form of symmetry is generally called the "hemimorphic class in the orthorhombic system." Its symbol is C_{2v}: the symbols of the four lattices are $\Gamma_0\ \Gamma_0'\ \Gamma_0''\ \Gamma_0'''$. In every case the content of the unit cell is divisible into four parts, corresponding to the ABCD of Figs. 2 to 6. The ten modes in the Γ_0 lattice are shown in Fig. 7, which will serve to show the numerical increase due to the introduction of the third dimension. Under each separate figure is given, beside the crystallographic symbol, another symbol which describes the shifts: D^x means a direct reflection across a plane parallel to yz; E^x_y a reflection across a plane parallel to yz, together with a shift parallel to the axis of y equal to half the y edge of the cell, and M^x a reflection across a plane parallel to yz, together with a shift parallel to the diagonal of the yz face and equal to half that diagonal.

Let us now see how the X-ray analysis distinguishes the mode. Let us imagine that Fig. 2 represented a number of pits in a plane reflecting surface. The surface could be used as a grating having many spacings instead of one. If, for example, we so placed it that the horizontal lines of the figure were parallel to the slit of the spectroscope the spacing would be equal to EJ: if the vertical, the spacing would be equal to EF. Again, if the grating were so placed that EK, for example, were vertical, the spacing would be the perpendicular distance between EK and FL. If the surface is pitted as in Fig. 3, the spacing when the horizontal line is parallel to the slit is the same as before: but when the vertical is parallel to the slit the effective spacing is only half what it was in Fig. 2. This follows from the fact that if we divided the surface into a number of vertical narrow strips, the diffracting effect of each such strip, for this position, depends on the total amount of reflecting surface contained in the strip, but not on its distribution along the slip. It does not matter that C and D are upside-down as compared to A and B. The strata consisting of C and D portions have interleaved the strata of A and B portions. This halving of a spacing of Fig. 3 as compared with Fig. 2 occurs only when the grating is placed so that the slit is parallel to the vertical line of Fig. 3, and not when any other line is vertical, except by some odd chance connected with the shape of the pits. In this way it is possible to distinguish between Fig. 2 and Fig. 3. The mode shown in Fig. 4 is distinguished by the halvings of both the horizontal and vertical spacings, and of no others. In the case of Fig. 6, as compared with Fig. 1, the spacing is halved when the slit is parallel to the

horizontal or the vertical line of the figure, and also whenever the grating is so placed that the parallel to the slit passing through one of the corners of a cell does not pass through the centre of that or any other cell, as, for example, if EO but not EK is parallel to the slit. It is therefore easy to distinguish each of the four modes.

If such a difference exists it may be expected to show in the external characteristics of the cell, giving it polarity. A good example is to be found in zinc blende. Layers of zinc and of sulphur atoms alternate with one another as in Fig. 9, all of them being perpendicular to a trigonal axis of the crystal. The distance between a zinc atom in the

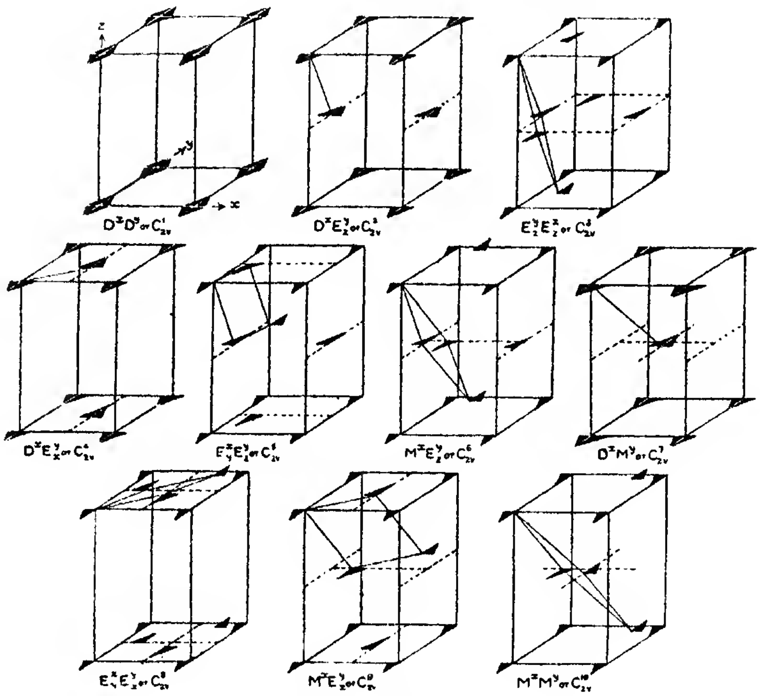

FIG. 7

Similar methods are applicable to the three-dimensional crystal. If, for example, we consider the case of C^2_{2v} or $D^x E^y_z$ we can show that, whereas in general the spacings of planes are such as are proper to a cell of the dimensions and form drawn in the figure, all planes of the form $lx/a + mz/c =$ an integer, show halved spacings, unless l is odd and m is even: which is sufficient identification of the mode of arrangement. The symbols a and c denote edges of the cell.

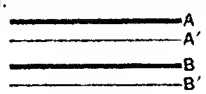

FIG. 8

If we follow this line of reasoning through all the thirty-two classes, we end, of course, with the discovery of the 230 modes which are known to exist: and with the identification marks of each, with certain qualifications. These last are of two kinds. One of them is general in nature and is a consequence of the fact that the X-rays can measure only the distance between two like points in neighbouring cells, say A and B. But they do not indicate any difference that may exist between AB and BA.

layer A to a zinc atom in the layer B is found without question by the X-ray method. Now we know from observation of the crystal that there is a difference between AB and BA: the crystal is polar. A crystal plate cut so that its faces are perpendicular to the axis shows different properties on its two sides: if heated, one face becomes positively and one negatively electrified. Whichever face we use in the X-ray spectrometer we obtain the same value for the spacing, and we find ourselves unable to detect any difference between the two aspects by means of the spectrometer observations.

We may see this point in another way. Suppose that Fig. 9 represents a section of a crystal consisting of two kinds of atoms, indicated respectively by full and empty circles. The arrangement clearly has no symmetry about a vertical line in the plane of the paper. But if X-rays were incident from above, as shown there would be equal reflections from the planes 11′ and 22′. If the incident rays were heterogeneous and a photographic plate were placed to receive the Laue reflections in the usual way, there would be a symmetry distribution of spots on either side of A, although there is no symmetry in the crystal to correspond.

It is only when we have taken other considerations into account and have determined the structure that we can establish the polarity of the crystal. We may take, for example, the fact that zinc blende is cubic, and therefore has four trigonal axes, a fact which we may discover from X-rays as well as from the external form. Also, the unit cell contains only one molecule of zinc sulphide, and may be drawn of the same form as in diamond: that is to say, its eight corners can consist of the six centres of cube faces and the two ends of a diagonal. If we put zinc atoms at the corners of the unit cell, the sulphur atom must lie either at the centre of the unit cell or at the centre of the regular tetrahedron formed by four of the corners of the cell: only by the adoption of one of these alternatives do we get the four trigonal axes. The former gives the rock-salt structure and is distinguished by the fact that the (100) and (110) spectra decrease regularly in intensity from lower to higher orders, whereas in the (111) spectrum the even orders are relatively greater than the odd.

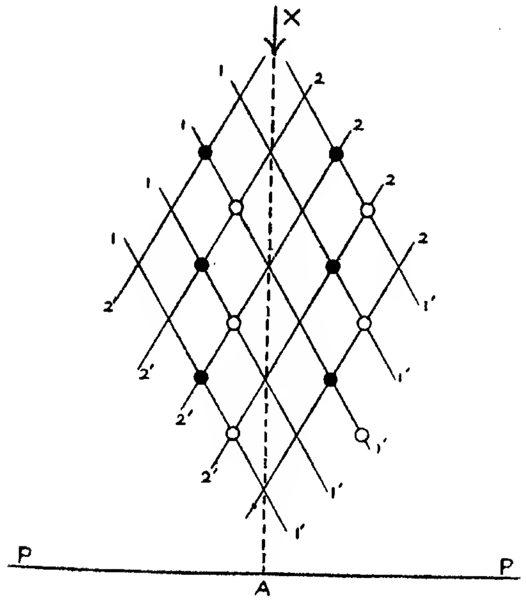

Fig. 9

In the latter alternative the even orders of (100) are relatively greater than the odd, (110) spectra are normal, and the second order of the (111) is abnormally small. It is easy to distinguish between the two cases. The latter is adopted by zinc blende. Each atom has the symmetry of Class 31, to which the crystal belongs, there being only one atom of each in the unit cell.

In this case we are successful from X-ray measurements alone in determining the mode of arrangement of the crystal, although the crystal is polar and the X-rays cannot detect polarity directly. We have been able to determine the structure completely, and the polarity then appears.

When the determination of structure cannot be carried far enough, the X-rays may fail to decide between the presence and absence of polarity. For example, resorcinol is an orthorhombic hemihedral crystal: this is known by its external form. The X-rays show that, this being so, its internal arrangement must be that of $M'M^{y}$ or C^{10}_{2v} in Fig. 7. If we had no help from the study of external form, or from any other source, we should not be able to decide between C^{10}_{2v} and the more symmetrical mode known as Q^{12}_{h}: the symmetry of the latter is obtained by adding a centre of symmetry to the elements of symmetry, possessed by C^{10}_{2v}: that is to say, by removing the polarity of the crystal. As a matter of fact the external form of resorcinol clearly shows polarity: or, if we could be sure that the molecule had no symmetry, we could infer that the crystal was unsymmetrical about the *xy* plane, there being only four molecules in the cell and all these being wanted to give the symmetry observed by X-rays. Thus there are cases where the X-rays cannot decide between two modes, one of which can be derived from the other by the addition of a centre of symmetry. As, however, the existence of a centre of symmetry can generally be decided by other means —for example, by such means as I have described above in the case of zinc blende or of resorcinol— this incapacity of the X-ray method is of no great consequence.

The addition of a centre of symmetry moves a structure from one class to another—Class 1 to Class 2, Class 31 to Class 32. Consequently, the X-ray methods are by themselves sometimes in doubt between two modes in different classes when they are rarely in doubt as to the mode within a class. It will readily be understood that the doubt as to class may be of far less importance than the doubt as to mode; though hitherto the former kind of difference has been given all the attention because it has been the only kind that could be observed. A very slight relative movement of the atoms would be sufficient to reduce the symmetry of the crystal from one class to another: but the change from one mode to another within the same class would mean a complete rearrangement of the molecules.

There are two cases in which the X-rays cannot distinguish between two modes in the same class. These are Q^{8} and Q^{9} in the enantiomorphous class of the orthorhombic system, and T^{3} and T^{5} in the tetratohedral class of the cubic system. The ambiguity disappears, however, if there are only two molecules in the unit cell, when the former alternative is alone permissible in each case: it would disappear also in any case in which the structure could be determined completely by any other means.

It has been known for many years, thanks to the work of Fedorow, Schonflies and Barlow, that the 230 modes of arrangement represent all the possible forms of internal crystal structure. In each mode of arrangement there is a relative disposition of planes, axes and centre of symmetry, which is characteristic of the mode, and the mode may be described in terms of these symmetries. This was the language used in the original work on

the subject, and the term space group was used, instead of the term mode of arrangement, in reference to the particular group of symmetry planes, axes and centre in space. When the subject is approached from the point of view of the X-ray worker, the language of the mode of arrangement has its special conveniences. A list of the 230 modes, and of the X-ray tests for each mode, has recently been published in the *Transactions of the Royal Society* by Astbury and Yardley. Lists of the same 230 space groups have already been published in different terms by writers on crystallography: recently a list by Wyckoff has been published by the Carnegie Institution of Washington, in which each space group is expressed in terms of the coordinates of the arrangement of points required to give each space group its special characteristics.

It may be of interest to look at these matters from a somewhat different point of view, which takes in the question of the permanence of the chemist's molecule when built into the solid structure.

In every crystal the unit can be divided into a certain number of parts, each of which has no symmetry of its own, but may be made to coincide with any other part by some combination of reflections, rotations and shifts. The number is always either one, two, three, four, six, eight, twelve, twenty-four, or forty-eight. The division into 230 modes of arrangement refers to the arrangements of these parts. In the case of a crystal of the rock-salt type both the positive and negative portions of the cell can be so divided. Very often the part in question is the chemical molecule. For example, the cell of the monoclinic prismatic class can be divided into four such parts. The X-ray measurements show that the unit cell of benzoic acid which belongs to this class contains four molecules. Also they detect the existence of the four parts, and determine the mode of their arrangement. It is natural to make the assumption that each part is a molecule. This, it may be noted, involves the existence of right- and left-handed molecules, as built into the crystal.

Sometimes the division into parts involves the division of the molecule. The molecule then consists of two or three or more parts, and therefore possesses a corresponding symmetry. For example, the naphthalene molecule in the naphthalene crystal contains two parts, and has a centre of symmetry. The molecule of FeS_2 in the crystal of iron pyrites consists of six parts, and has a centre of symmetry and a trigonal axis. Each of the two atoms in the rock-salt cell, sodium and chlorine, has—that is to say its relations to its neighbours have—forty-eight parts, and therefore the full symmetry of the crystal.

Much more rarely a part consists of more than one chemical molecule. So far a few instances have been met with. The "part" in the crystal cell of sulphur certainly contains two, perhaps more, atoms. Miss Yardley finds that the "part" in the fumaric acid crystal contains three, perhaps six, of the molecules as ordinarily defined $(COOH.CH:)_2$. In the cell of α-naphthylamine at least three molecules go to a part. The part has no symmetry, so that the molecules that compose it differ from each other. These are really examples of polymerisation in the crystal.

Is the grouping of the atoms in the molecule as displayed in chemical reactions maintained without change? When the first results of the new methods were published, with their determinations of diamond and rock-salt structure, there was some unnecessary alarm as to the apparent disappearance of the molecule. If there had been anything to suggest a complete disruption of all the alliances in the molecule, which had been so long and so successfully studied by the chemists, the alarm would have been justified. Atomic bonds would have been annoyingly variable and dependent on conditions, and we should have been put back to the starting-point in the investigation of the solid. This condition of things appears, fortunately, to have no existence. The conclusions of chemistry are carried into the solid, with only such modifications as might reasonably be expected. Our new science is in full and close alliance with chemical science already established: it is in fact a constant and delightful experience to find some direct confirmation or illustration of an inference already drawn from other sources. So far as experience has to tell us, the chemical molecule generally takes its place as such in the crystal structure with little change.

To sum up, we are now able to replace the rough division into thirty-two by the finer division into 230. This is advancing a whole stage towards the final solution of the structure problem. We carry the analysis right up to the limits which can be foreseen by the mathematical investigation of the geometry of space. We require only a sufficient number of X-ray measurements; if these can be obtained, the crystal then—with certain additional information as to polarity—can be assigned to its particular mode or space group, with one or two exceptions as already noted. It may be that the structure of the crystal is so simple that having got so far the full solution is already in sight. In the vast majority of cases this is not so; we have only come to the end of the second stage of the work.

The first stage was complete when we had found the dimensions of the crystal unit cell: the second is completed when we know which of the 230 possible arrangements of molecules, or, in other words, space groups, the crystal structure follows.

If the structure of the crystal is not yet obvious—and in the great majority of cases this is far from being the case—we enter on a third stage, in which the mode of procedure is less stereotyped and more difficult, perhaps all the more interesting. We have now to find if we can, the arrangement of the atoms within the cell, to which task the knowledge already gained is an indispensable though, it may be, a quite insufficient contribution.

As I have said already, the X-rays do not tell us directly the relative positions of the atoms within the unit cell. They have, however, much to tell us as to the relative intensities of the different orders of reflection by each plane, and these must depend on the atomic arrangements. It is to be admitted, however, that we are as yet unskilled in the interpretation of this evidence. We do not completely understand how varying conditions affect intensities of reflection, though we have learnt a great deal through the work of W. L. Bragg, Darwin, Compton,

and others. And, of course, when the cell contains many molecules, their positions being as yet unknown and their separate contributions to the intensities in any case doubtful, the observations of intensity are very difficult to make use of, though they can be accurately measured. We can only avail ourselves of such bold indications as that a very strong reflection implies the location of many atom centres on or near the plane in question, particularly if there are higher orders: or we may find ourselves able to show that an especially strong second or third or other order implies the adoption of some particular alternative arrangement. A very interesting example of a general influence of form upon intensity is to be found in the reflections from the fatty acid layers which have been investigated by Muller and Shearer. The first, third and other odd orders are much more intense than the second, fourth, and other even orders. A simple explanation is found in the fact that these long chains face opposite ways alternately, and that the number of scattering centres is distributed fairly evenly along their length. At the ends, however, the uniformity of distribution is interrupted; at one end, probably the carboxyl end, there is an excess per unit length: at the other, the methyl end, a deficiency. Thus we may say that the effect on an odd order of the spectrum due to a single layer, the thickness of a layer being twice the length of a molecule, contains a factor :—

$$A \sin(\omega t - a) - B \sin(\omega t - a - \overline{2n+1}\pi) = (A+B) \sin(\omega t - a).$$

The factor for an even order is :—$(A-B) \sin(\omega t - a)$. If at both ends there had been an excess of scattering centres, we should have found the even orders stronger than the odd: the effect we find, for example, in the (111) planes of rock-salt. In the case of the simpler inorganic crystals like rock-salt, diamond, and so on, intensity observations are conclusive as to the structure: in the case of iron pyrites or calcite they are very nearly so. But in the case of quartz, where the cell contains nine atoms, still more in the case of an organic compound, they do not carry us very far. We hope that greater experience will give us in the future the power of using them to better advantage.

In what other direction then shall we look for additional means of approaching more nearly to the final solution of the problem of structure?

The answer to this question will take account of all the store of physical and chemical knowledge which we already possess. Having solved, wholly, or in great part, the structure of some of the simpler crystals, and being able to proceed in all cases, even of the most complicated crystals, to the determination of the number of molecules in the cell, and of their mode of arrangement, we must try to correlate what we have found with the properties of the crystal. By that means we shall become gradually more certain of the general connexion between the structure and its physical and chemical properties; we shall become able to settle further structural details in various cases, and so, by alternate and mutually supporting advances, we may hope to reach our goal.

Let us consider what is being done in this direction. First of all there is the question of the distribution of the atoms in space. Given so many atoms, to be packed into a cell of known dimensions, what information have we as to the space that each must occupy? The answer to the question cannot be simple, because we may not expect that the atoms are always to be treated as spheres, still less as spheres of constant radius. It is as generally difficult to state the distance between one atom and another as to state the distance between a table and a chair. Nevertheless, the atom-radius is a useful conception, especially when its dependence on the nature of combination is taken into account. The question has been considered by W. L. Bragg, Wyckoff, Davey, and others, and it appears that an atom does make a definite contribution to the distance between its centre—when it can be assumed to have a centre—and the centre of a neighbour, so long as the nature of the bond remains the same. This is a valuable contribution to the study of structure. It is proved by the examination of simple structures like those of the alkaline halides, and we may assume its reliability in our attempt on more complicated problems. And, of course, it is interesting from the point of view of atomic structure itself, and atomic linkages.

The radius seems to depend on the tightness of the bond as in bismuth or in graphite, where there are two kinds of bonding, and the plane of cleavage cuts across all the longer distances from centre to centre. In calcium fluoride the centres of calcium atoms are closer together than they are in the metal itself in spite of the interposition of the fluorine atoms; and in calcium oxide they are still closer. The change in the type of the bonding has altered the value of the radius.

There is also the very interesting but still more unsettled question of the mutual orientation of the bonds between an atom and its neighbours. It is, of course, the carbon atom which is the occasion of this problem in its most pressing form. In the diamond the exactly tetrahedral arrangement of bonds is associated with great rigidity, which implies great stiffness of orientation. The analysis of the structure of graphite has lately been carried by Bernal to a stage very near completion, but the only point in any doubt is unfortunately the very one as to which certainty would be welcome. Has the great weakening of one bond interfered with the realtive orientation of the other three? Debye thought that the structure was trigonal, and that the atoms were arranged in layers which were like the layers of diamond, except that they were flattened out without a sideways extension of the network. This would involve a closer approach of carbon atom centres from 1·54 A.U. to 1·45 A.U.; against which no obvious objection can be offered, but it would be interesting to know how it happened. Hull believed the structure to be hexagonal, and that the layers remained as in the diamond. Bernal, having found some good graphite crystals to which the single crystal methods could be applied, finds that Hull is correct as to the hexagonal structure, but inclines to the belief that the layer is flattened.

In the latter case, we must suppose that the carbon atom has three very strong bonds almost coplanar with the carbon, and one weak bond at right angles to this plane.

The question arises in another form in the investigations of the long carbon chains by Piper and others, and especially by Muller and Shearer. If the chains are formed by the linking of carbon atoms together in such a way that the junctions of one atom to its two carbon neighbours are inclined to one another at the tetrahedral angle of 109°28′, as in diamond, then there are three possible forms of chain. In one of them, each two carbon atoms imply an increase of 2·00 A.U. in the length of the chain, and, in a second, an increase of 2·44 A.U. In these two cases the carbon atoms of a chain can lie in a plane. With one exception, all the cases examined show one or other of these two rates of increase. The third form of chain is a spiral, for which the growth of each single atom added is 1·12. In one case this rate of increase is found to hold: it is that in which the chain contains a benzene ring. This agreement between the calculation and experiment shows with some force that the relative orientation of the bonds is maintained. Even when two or four hydrogens are stripped from the chain at various points, so as to leave a double or triple bond between consecutive carbon atoms, to adopt the ordinary chemical language and theory, no reasonable change is found in the length of the chain. This does not mean that there is no change in the distance between neighbours: such a change would be small and might escape detection. But it does mean that there is no great change in the general straightness of the chain, such as might be expected from any large change in the mutual orientation of the bonds between the carbon atom and its neighbours.

In calcite the three oxygens which surround a carbon atom must lie in one plane. It is supposed, however, that in this case the bonds are electrostatic: the carbon atom has lost its four valency electrons, and with them its powers of tetrahedral orientation.

Now if we can discover the extent to which an orientation is maintained under different conditions, we are provided with one more guiding principle in our attempt to discover the structure of the crystal which contains carbon atoms. And, of course, the organic compounds centre round the carbon atom and its tetrahedral structure.

The question of orientation in respect to other atoms is more obscure, but it is clearly one of importance. There must be some reason why ice has such an open structure, and here the oxygen atom is largely concerned. In the ruby the oxygen atom has no plane of symmetry in relation to its neighbours. In organic substances the great emptiness of the structure implies that atoms are attached to one another at points which have definite positions on the surfaces of the atoms and are limited in number. And, generally speaking, the consideration of organic crystal structure is against any idea that atoms and molecules are to be treated as spheres surrounded by uniform fields of electric force, except in certain cases where by loss or gain of electrons an atom has been reduced to the outer form of one of the rare gases. They must have highly irregular fields, having forms which more or less resist any change. The weak bonds which hold molecule to molecule in the organic substance are not due to electron sharing as in diamond, or to ionisation as in rock-salt, but to an intermingling of stray fields belonging to definite positions on the surfaces of the molecules.

Our attempt to discover the effect of orientation is part of a general attempt to discover the field of force of the atom, which is naturally a very difficult matter. But if we can learn only a few rules, even empirical rules, we are so much the further on our way.

Yet another obvious and most important source from which help may be obtained is to be found in chemistry itself. Although the chemist has had no means until now of measuring distances and angles, he has been able to build up a wonderful edifice of position chemistry. An atom A of a molecule is certainly linked, it may be to B, and not to C; or again, of a number of atoms of the same nature and contained in the same molecule, so many must be alike, and so many may be different.

The chemist has, for example, come to the conclusion that the naphthalene molecule is a double benzene ring, and the anthracene a triple benzene ring. The X-ray observations show that one of the sides of the unit cell of the latter crystal is longer by 2·5 A.U. than the corresponding side of the other, all other dimensions of the two cells being very nearly the same. The width of the hexagonal ring in the diamond is 2·5 A.U., so that on the one hand the chemical evidence suggests that the length of the molecule is parallel to that edge of the two cells which shows differing values, and on the other the X-ray conclusions give material support to the chemical view. Let us take another example from basic beryllium acetate $Be_4O(C_2H_3O_2)_6$. The substance is remarkable for the case with which it sublimes into a vapour consisting of whole molecules, from which we may infer that the molecule does not suffer much change in the process. The relative positions and mutual alliances of the atoms are nearly the same when the molecule is free as when it is built into the solid. From the X-ray evidence we learn that the molecule has four intersecting trigonal axes. We must place the unique oxygen at the centre of a regular tetrahedron, and the four beryllium atoms at its corners. Each of the six acetate groups must be associated with one of the tetrahedron edges, and in such a way that the four trigonal axes are maintained. This necessitates, as crystallographic theory shows, the existence of a dyad axis through the middle points of each pair of opposite edges of the tetrahedron. The $C_2H_3O_2$ groups must be added so as not to interfere with the existence of these axes. If they are placed correctly for the trigonal axes, each of them has a dyad axis of the kind mentioned. All this agrees with the chemical evidence as partly stated in the formula, which implies :—

1. That there is one oxygen differently situated to the rest.
2. That the four beryllium atoms are all alike.
3. That the acetate groups are all alike.

Further, chemists would say that the carbon atoms

are not alike; in that case, they must both lie on the dyad axis, since if they did not they would necessarily be symmetrically placed with respect to that axis and would be equivalent. On the other hand, the oxygen atoms in the acetate group cannot lie on the axis if, as is probable, they are equivalent to one another. They must be placed symmetrically with respect to the dyad axis. As to the hydrogens, we must assume either that they do not count, which is not at all unlikely, or that they are not all alike. It is impossible to place eighteen hydrogen atoms so that the group has four intersecting trigonal axes and that every hydrogen is like every other. The molecule has no plane of symmetry, the fault lying with the oxygens. It could not be due to the hydrogens because there are marked differences in the intensities of reflection of pairs of planes, which differences would not exist if there were planes of symmetry, and would be small if due to dissymmetry in the positions of hydrogens only. It is by reasoning along such lines as these that X-ray evidence and chemical evidence can help each other. Many other instances might be given; indeed, no complex crystal can be studied with success without calling in the assistance of chemical arguments.

A fourth example of the connection between arrangement and properties is to be found in the recent work by W. L. Bragg on the indices of refraction of crystals. It has been found possible to calculate the indices of refraction of calcite, given the dielectric capacities of calcium, carbon and oxygen atoms separately. The difference between the two principal refraction indices is almost entirely due to a difference between the dielectric capacities of a set of three oxygen atoms, at equal distances from one another, when placed :—

1. So that the plane in which they lie contains the direction of the field.

2. So that this plane is perpendicular to the field.

If we are able to calculate the refractive indices on these data, then it must be possible to find conditions governing the arrangement of the atoms, when we know the composition of the crystal and its refractive indices. For instance, the near equality of the refractive indices of potassium sulphate implies that the dielectric capacity of the SO_4 group is much the same in all directions, and this is in agreement with the hypothesis that the oxygen atoms are grouped in some sort of tetrahedral fashion about the sulphur atom.

There are still other connexions between structure and properties which we begin to understand, and can use in proportion to our understanding. The cleavage plane and the occurrence of certain faces in preference to others are connected with the nature of the bonds and the size of the spacings. We are not surprised to find that in bismuth, or graphite or naphthalene the cleavage plane cuts across the ties which we should expect to be the weakest of those that bind the molecules together; or again, that natural faces follow the planes that are richest in atoms or molecules and may be assumed to contain relatively large numbers of linkages. In naphthalene the cleavage plane passes between the ends of the molecules, where the β hydrogens are, and where there is a deficiency in the number of scattering centres, as the X-rays indicate by the strengths of several orders of the (001) reflection. The other faces found on the crystal cut across the ties at the positions of the α hydrogens.

There are many other connexions between the structure and other properties of a substance, such as dielectric capacity, rigidity, and compressibility, conductibility both thermal and electric, magnetic constants. In fact, the only properties of solid bodies which are not directly and obviously related to crystal structure are those, few in number, that depend on atomic characteristics alone, such as weight; and the absorption coefficients for α, β, γ and X rays, all the rays which involve high quantum energies. With few exceptions every aspect of the behaviour of a solid substance depends on the mode of arrangement of its atoms and molecules. We have, therefore, an immense field of research before us, into which the X-ray methods have provided an unexpected and welcome entrance.

They tell us directly, as I have said, the number of molecules in the crystal unit cell, and the mode of their arrangement with such determination of lengths and angles as are required to define the mode of arrangement in full. They leave us then to ally our new knowledge to all that we possess already as to the physical and chemical properties of substances. By this comparison we hope in the end to determine the position of every atom, and explain its influence through its nature and position upon the properties of the substance. It is the chemistry of the solid that comes into view, richer in its variety even than the chemistry we have studied for the past century, and possessing an importance which is obvious to us all. Every side of scientific activity takes part in this advance, for all sciences are concerned with the behaviour of matter.

CHEMISTRY IN HERODOTUS

In the *Chemiker Zeitung*, 1924, No. 1, p. 1; No. 7 pp. 29-31, and No. 8/9, p. 38, Prof. E. O. von Lippmann has an interesting article, entitled *Technologisches und Kulturgeschichtliches aus Herodot.* Herodotus (489-429 B.C.) included a large number of observations of scientific interest in his great work, but hitherto they have attracted very little attention, probably because they are not gathered together in one place, but are scattered throughout the book and often introduced only incidentally. Prof. von Lippmann has been industrious enough to collect these isolated details, and the material he has thus accumulated will prove of great assistance to those who are engaged upon the study of early chemistry. The article—of which it is scarcely possible to make an abstract—is divided into four sections, which deal respectively with (i) the Elements, (ii) Mineral Substances, (iii) the Metals, and (iv) Organic Substances. The annotations are as scholarly and as enlightening as would be expected from the learned author of *Die Entstehung und Ausbreitung der Alchemie.*

SOCIETY OF CHEMICAL INDUSTRY

CHEMICAL INDUSTRY DINNER

The Autumn Dinner, which will be under the auspices of the Society of Chemical Industry and the Chemical Industry Club, will be held in the Edward VII Rooms of the Hotel Victoria, Northumberland Avenue, London, W.C. 2, on Friday, November 14, at 7 for 7.30 p.m., and will be presided over by Mr. W. J. U. Woolcock, C.B.E., President of the Society.

A circular letter with further particulars and a form of application for tickets has been sent out to the members.

BACK NUMBERS OF JOURNAL

The General Secretary will be glad to hear from Members or Subscribers who have copies of the *Journal* for January 5, 1923, or January 4, 1924, that they are willing to dispose of to the Society.

FORTHCOMING EVENTS

Oct. 1. SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS, in the Chemical Society's Rooms, Burlington House, Piccadilly, London, W. 1, at 8 p.m.

The following papers will be read:—"The Determination of Coconut Oil and Butter Fat in Margarine," by G. D. Elsdon and P. Smith. "A Preliminary Note on the Composition of the Fat of Goat's Butter," by F. Knowles and J. C. Urquhart. "The Quantitative Estimation of the Degree of Hydrolysis of Gallotannin by Tannase," by Miss W. N. Nicholson and D. Rhind. "The Pemberton-Neumann Method for the Estimation of Phosphorus," by Miss M. B. Richards and W. Godden. "Application of 'Formal Titration' to the Kjeldahl Method of Estimating Nitrogen," by W. S. Shaw. Informal Dinner will be held for Members and their friends at St. James' Restaurant, 178 Piccadilly, at 6.30 p.m.

Oct. 2. SOCIETY OF CHEMICAL INDUSTRY, *Bristol Section*. Joint Meeting with the Institute of Chemistry, the Chemical Department of the University (Woodland Road), Bristol, at 7.30 p.m. "The Present Position of the Catechin Chemistry," by Dr. Nierenstein.

Oct. 3. SOCIETY OF CHEMICAL INDUSTRY, *Manchester Section*, at the Textile Institute, 16, St. Mary's Parsonage, Manchester, at 7 p.m. "Chemistry and Industry," by W. J. U. Woolcock, C.B.E., President of the Society of Chemical Industry.

Oct. 22. THE FARADAY SOCIETY, in the Geological Society's Rooms, Burlington House, Piccadilly, London, W. 1, at 5 p.m. Discussion on "The Physical Chemistry of Igneous Rock Formation," with an introduction by Dr. J. S. Flett. Papers are expected from Prof. C. H. Desch, Dr. J. W. Evans, Prof. J. W. Gregory, A. F. Hallimond, Prof. P. Niggli, Dr. A. Richardson, Dr. A. Scott, Mr. G. W. Tyrrell, and Prof. W. E. S. Turner.

CORRESPONDENCE

ARSENIC AND THE OYSTER

Sir,—Why, I venture to ask, do you single out the innocent but succulent oyster and accuse it of a base predilection for arsenic? Surely a humble mollusc cannot be expected to be as fastidious in its diet as its more highly cultured neighbours—the fishes. Three parts per million is not excessive for an animal condemned to feed on the bottom of the sea; why, even the plaice, which has two eyes, and the whiting which feeds not on the ocean bed, may contain this much, and the aristocratic cod, so says Prof. Bang, on occasion contains more than four parts. Pray, Sir, acquit the oyster and let us enjoy it in peace.

In conclusion I beg you to inform me whether the "Walrus" and the "Carpenter," either or both, died of arsenical poisoning after their lament over the gentle oysters they decoyed and betrayed?—I am, Sir, etc., "ARSENICUM"

September 19, 1924

THE CHEMIST IN THE PROVINCES

Sir,—Now that we have reached the end of our English summer, the time will soon be upon us when we shall receive demands for Annual Subscriptions. The typical young chemist in the provinces, who, anxious to keep up-to-date has joined several societies, may be faced with a bill of anything up to £10. He is entitled to ask himself whether he is receiving value for money?

The young chemist emerges from the University with a degree. Urged by his professor he probably joins the Chemical Society. He then finds that although he possesses his degree he is not considered a genuine chemist unless he joins the Institute, so if he is sufficiently enthusiastic he takes the A.I.C. He now goes forth into chemical industry a "pukkha" chemist. Still anxious to keep abreast of knowledge he enters the Society of Chemical Industry, and, if a super enthusiast, he joins a fourth society connected with some specialised branch of his profession.

Let us consider the case of the chemist who lives away from London. What does he get in return for his hard-earned cash? Let us take the various societies separately.

(*a*) *Chemical Society*

All that the provincial chemist receives for his £3 per annum is the monthly journal, consisting entirely of papers on "pure" research, *e.g.*, Isomerism in the Timbuctoo acids. If the young chemist is honest with himself he finds that 99 per cent. of the contents do not interest him, and that 50 per cent. cannot be properly understood by him. If he remains a member for many years, he finds himself landed with a collection of hefty tomes which he cannot dispose of.

He learns that the Chemical Society has a fine library of which he can make very little use. It might just as well be in Jericho.

(*b*) *Institute of Chemistry*

This society for 30s. per annum registers the young aspirant as a genuine chemist. It bestows

upon him every two months a journal which he may or may not find interesting. It makes him a member of a local section, at which on certain evenings in the winter he can meet perhaps a dozen other chemists and discuss such absorbing topics as "Should the Institute have an Academic dress?" etc.

(c) *Society of Chemical Industry*

For £2 15s. per annum the young chemist receives a weekly *Journal*. This *Journal* is certainly a very good one, though occasional articles by prominent professors make him wonder if he knows any chemistry.

This Society also makes him member of a local section. Once in two or three years, perhaps, the young chemist hears of a paper which interests him and attends a meeting. The question: "What becomes of all the old chemists?" is supplied with a full and complete answer.

So much, then, for the various Societies. Is there any genuine reason why the young chemist should be called upon to pay several annual subscriptions? Surely one single Society alone could do the work at present done by three.

The function of a chemical society is simply to look after the status of the chemist, keep a register, and enable its members to keep abreast of chemical knowledge both pure and applied. It should publish a weekly journal and have occasional local meetings, and establish a library in every local section.

The journal, in addition to matters of topical and professional interest, should be modelled on the lines of "Chemistry in the Twentieth Century," *i.e.*, the articles should consist of general accounts of progress in various fields of chemistry, and should be written by specialists. These articles enable the ordinary chemist, who is really a specialist himself, to obtain a good knowledge of progress in other branches of chemistry, without overwhelming him with a mass of indigestible detail. The consulting of original papers is then optional.

The Society should, as now, receive accounts of original researches from its members, but only the titles of such papers should be published in the *Journal*.

If the chemist finds that one of these papers is of particular interest to himself, he should be able to obtain a full copy from the Secretary of the Society, or copies of all papers communicated to the Society should be kept at the libraries of the local sections.

Whether there should be meetings of local sections is a matter of opinion. If held, they should certainly be much wider in scope and of a definitely social character. The topics should be as broad as possible, with the object of enabling the chemist to take the widest possible view of his profession. The average chemist is deeply interested in his work, and is not above attending meetings if they are worth it. At present we chemists suffer from too many meetings, and too narrow a view of our profession.

To sum up, my points are these:—(1) The young chemist cannot afford to be a member of several societies.

(2) There is no valid reason why all the interests of the chemist should not be looked after by one single society at a reasonable fee.

(3) The chemist in the provinces should be catered for equally with the chemist in London.

(4) The literature of chemistry should be given a wider scope and should have a more general appeal. —I am, Sir, etc., "YORKIST"

Leeds

BENZOL RECOVERY

SIR,—In the issue of September 12, Vol. 43, No. 37, B. 739, you published an extract from a paper read by Monsieur Edouard Urbain at the Centenary Congress of the Société Technique on "Activated Carbon and Silica Gel."

From this paper one would naturally draw the inference that the benzol-recovery plant at the Grenoble gasworks was erected to the designs of Monsieur Edouard Urbain.

I should, therefore, like to prevent any misunderstanding, and state the facts regarding this plant verified by two independent experts from this country, who visited Grenoble to see the plant in operation.

The erection was carried out by the Société Anonyme pour l'Utilisation des Combustibles, of Paris, to the design of Friedr. Bayer and Co., Leverkusen, and under their guarantees. The installation of steam coils in the filters to reduce the steam consumption (specially mentioned in Monsieur Urbain's paper) was carried out during the course of the erection of this plant on the instructions and to the design of the Friedr. Bayer Co. after their experimental filters at Leverkusen had been fitted and tried out with these special coils and data obtained therefrom as to the resulting economy. These experiments were carried out at Leverkusen during 1923.

Further, since the plant has been put in operation, a prefilter has been added in order to minimise the risk of fouling the highly active "T" carbon with foreign bodies which cannot be driven out by means of highly super-heated steam, or only with great difficulty. This pre-filter is again to the Friedr. Bayer Company's design and filled with their prefilter carbon. This would have been embodied in the original design for the Grenoble plant, but it was assumed that the gas would be clean enough to be dealt with directly in the benzol carbon filters.

In my paper read before the Chemical Engineering Group of the Society of Chemical Industry on March 7, 1924, the Grenoble plant was described, and a diagrammatic slide of the arrangement thereof shown. However, figures as to plant operation could not be given at that time, as it had only been in operation for some five to six weeks.

I feel it only right and fair to Messrs. Friedr. Bayer and Co. that I should draw your readers' attention to these facts as, although the Société Anonyme pour l'Utilisation des Combustibles have the sole exploitation of this Bayer process in France, my firm, Messrs. Simon-Carves, Ltd., 20, Mount Street, Manchester, has its exploitation for the United Kingdom, and we work in the closest co-opera-

tion with Messrs. Friedr. Bayer and Co., all information being pooled for our common use.

Owing to the French occupation of the Ruhr, there was difficulty in obtaining delivery of the active carbon from Messrs. Friedr. Bayer and Co.'s Leverkusen works, and apparently one of the three filters at the Grenoble plant was filled with carbon manufactured according to Monsieur Edouard Urbain's process. The Grenoble plant is one of the many solvent extraction plants using the Bayer process and carbon, amongst which there are in operation and in course of construction plants extracting over 2000 tons of benzol per annum.—I am, Sir, etc

Knutsford VIVIAN F. GLOAG

September 19, 1924

PERSONAL AND OTHER ITEMS

Prof. Alex. Findlay has accepted an invitation to visit Stanford University, California, as Acting-Professor of Chemistry for the three quarters of the academic year, January to August, 1925.

Sir Ernest Rutherford, Prof. Donnan and Sir Charles Parsons have arrived in Philadelphia for the celebration of the centenary of the Franklin Institute.

Mr. E. Craig Porter, B.Sc., Ph.D., who has been appointed works chemist at the factory of Lotus Ltd., Stafford, graduated in technical chemistry at Manchester University, and gained the degree of Ph.D. for research work on hide substances in the leather department of Leeds University under Prof. Procter.

Mr. J. G. A. Skerl, research assistant to Prof. P. G. H. Boswell, of the University of Liverpool, has been appointed by the British Cast Iron Research Association to direct an investigation on moulding sands in the Refractories Department of Sheffield University and in the foundries of members of the Association.

Prof. B. I. Slorzov, a Russian biochemist whose death is announced, had done much work on tissue enzymes.

The British Research Association for the Woollen and Worsted Industries has awarded research fellowships for 1924-25 to Mr. R. Burgess to enable him to continue investigations on the bacteriology and mycology of wool at University College, Nottingham, and to Mr. J. E. Nichols to investigate the wool fibres of various breeds of sheep at the Animal Breeding Research Department of the University of Edinburgh. An advanced scholarship, tenable at the Scottish Woollen Technical College, Galashiels, has been awarded to Mr. H. Maldwyn Williams.

The University of Pennsylvania announces that honorary degrees of D.Sc. are to be conferred on, amongst others, Sir W. H. Bragg, Sir C. Parsons and Prof. Pieter Zeeman, of the University of Amsterdam.

It is officially announced that the British Empire Exhibition will be closed on November 1. The question of reopening the Exhibition next year is still in abeyance.

The late Mr. W. H. Revis has left £10,000 and a share in £35,000 to the University College of Nottingham. The bequest will probably be utilised to provide scholarships and short-term fellowships at the University.

Sir George Thomas Beilby, F.R.S., LL.D., D.Sc., who died on August 1, aged 73, left estate of the gross value of £163,689, with net personalty £154,248.

A tablet to the memory of Henry Fox Talbot, the founder of modern photography, was unveiled in the library of the Royal Photographic Society on September 13.

Mr. H. K. G. Bamber, for many years a director of the Associated Portland and British Portland Cement Companies, has been killed in a motor accident.

We regret to announce the death of Mr. E. H. Brown, an old member of the Society of Chemical Industry, who had lived some years in Russia and was latterly executive officer of the Pembroke, Ontario, branch of the McGuire, Patterson and Palmer Co., match manufacturers.

Smokeless Fuel

The Corporation of Glasgow is installing a five-unit battery of Maclaurin producers to manufacture smokeless fuel and supply industrial gas to the Dalmarnock electricity station. The plant will be at work in a few weeks and will supply gas for firing boilers at the station at 1·01d. per therm.

Arsenic, Calcium Arsenate and the Boll Weevil

The supply of arsenic compounds for the control of the boll weevil pest of the cotton crop has of late received much attention in the United States, owing to the great fluctuations of prices and the difficulty, at times, of obtaining supplies. A contribution to the study of the problem has been made by Mr. H. W. Ambruster, who has reprinted, under the above title, various papers and addresses from technical and trade papers. The pamphlet (pp. 42, price 50 c., Barr-Erhardt Press, New York), which discusses the supply of arsenic, the manufacture of calcium arsenate, phases of the state of supplies of arsenic and its use for controlling the boll weevil, provides a useful summary of certain aspects of the question.

BRITISH INDIA

First Sugarcane Forecast, 1924—1925

According to reports received from provinces, which contain, on an average, 93 per cent. of the total area under sugarcane in India, the total area planted with the sugarcane is estimated at 2,566,000 acres, as against 2,715,000 acres at the corresponding date of last year, or a decrease of 5 per cent. Weather conditions at the time of planting were not generally favourable, and the present condition of the crop is, on the whole, fair, but much depends on the future course of the monsoon.

First Forecast of the Sesamum Crop, 1924–25

A memorandum based on reports received from provinces which comprise 80 per cent. of the total sesamum acreage of India states that the area under crop, so far reported, is 2,115,000 acres, as compared with 2,100,000 at this time last year, or an increase of 1 per cent. Sowings still continue in many places. The weather at sowing time was not quite favourable, but the present condition of the crop, on the whole, is reported to be fair.

REVIEW

Charts of the Chemical Reactions of the Common Elements. By John A. Timm, Ph.D., Pp. ix + 81. New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1924, Price 10s.

This book reviews the chemistry of the common elements, arranged alphabetically in the form of charts of their occurrence and reactions, and of equations related thereto.

The charts are ingenious, and present a bird's-eye view of the chemistry of each element, including reactions employed in analysis and manufacture. Small numerals attached to formulæ in these charts refer to equations for the elements which follow. The equations offer no ground for criticism from the point of view of accuracy; and the method by which they are built up is no doubt the one commonly employed, apart from the ionic notation—*e.g.* :—

$$2HNO_3 \rightarrow H_2O + 2NO + 3O$$
$$3O + 3Cu \rightarrow 3CuO$$
$$\underline{3CuO + 6HNO_3 \rightarrow 3Cu(NO_3)_2 + 3H_2O}$$
$$3Cu + 8HNO_3 \rightarrow 3Cu(NO_3)_2 + 2NO + 4H_2O.$$

Yet it is necessary to warn the student that this procedure is a means of arriving at a result rather than a plan of nature's footsteps; otherwise he may ask why three atoms of oxygen are shown to be liberated, and then to produce three molecules of copper oxide, since these things are not known to occur. One doubts, therefore, the wisdom of presenting the student with lists of equations in the bald fashion of this book—there are no fewer than sixty "sulphur equations"—without a word of explanation as to their limitations as expressions of facts. If it is said that this is not a textbook but merely a review, then the question arises whether the good student should not prepare his own review, and whether the indifferent student will ever become a good student by having his review prepared for him.

One might prophesy that piles of these books will be found left upon the doorsteps of examination halls in America, and perhaps in this country, but whether the comprehension of nature and the advancement of chemical science will be promoted by their use is another question.

R. M. Caven

COMPANY NEWS

NOBEL INDUSTRIES, LTD.

At the fifth ordinary general meeting, Sir Harry McGowan, K.B.E. (chairman and managing director), said that despite a continuance of uncertain commercial conditions throughout the world, the hope expressed last year that the results for 1923 would not fall short of those for 1922 had been amply realised. During the past few years, the Company had been rapidly consolidating its position in the production of its chief line of manufacture, blasting explosives and accessories. The home trade formed an important part of the business, and he believed that customers were satisfied both with the service and selling prices, which latter compared most favourably with those ruling prior to the war. This had only been made possible by the policy of concentration of manufacture and scientific research adopted by the company. The company possessed large interests in many foreign companies, including Canadian Explosives, Ltd., and Chilian Explosives Co. The Cape Explosives Works in South Africa, and Nobel's interests in South Africa had been merged into a new company, the African Explosives and Industries, Ltd., the shareholders being De Beers and Nobel Industries, Ltd. Interests had also been acquired in explosives and fuse factories in Czechoslovakia, Hungary and Rumania, and business in the Far Eastern countries, such as India and China, was well established. By application of scientific factory administration, the company was now producing a superior quality of goods as compared to pre-war days. The board was quite satisfied with the year's trading and saw no reason to suppose that the complete year's figures for 1924 would be less satisfactory than those for 1923, in which circumstances the directors would consider whether the time was not opportune to adopt the policy of paying an interim dividend on the ordinary shares, and it was hoped to make a declaration on the subject towards the end of this year.

GAS LIGHT AND COKE CO.

An agreement for amalgamation with the Brentford Gas Company has been made, with effect, subject to parliamentary sanction, from January 1, 1926. The amalgamation will be the largest in the history of the British gas industry, giving the Gas Light & Coke Co., already leading in the world's gas supply, an area nearly 40 miles long by, in places, 15 miles wide. The Gas Light & Coke Co. has an issued capital of £23,165,280 and the Brentford Company a capital of £2,058,545. The latter company has already absorbed the Richmond, Harrow and Stanmore gas companies.

BRITISH CELANESE

During the year ended February 29, 1924, there was a loss on trading of £34,478 and a total loss, allowing for debenture interest, and losses on cancellation of erection contracts, of £74,048, without providing for depreciation. The special propaganda programme has been charged to revenue and had the expenditure been capitalised, there would have been a trading profit. The total deficit now stands at £565,827. Sales during the last few months have been satisfactory.

ASSOCIATED PORTLAND CEMENT MANUFACTURERS

The reconstruction of the board of this company has now been completed. The Hon. F. C. Stanley, and Messrs. A. White, H. Holt, W. F. Roch and A. Brooks have resigned from the board and Lord Meston, Sir J. A. Horne, Mr. W. J. Firth and Mr. P. J. Pybus have been elected directors. Economies have been made in administration and an intensive campaign of propaganda is to be carried out.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech. ..	£23 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	.. £45 per ton.
Powder	.. £47 per ton.
Acid Hydrochloric	.. 3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	.. £21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric ..	.. Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali ..	.. £6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder	.. Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	.. £7 per ton, packages extra.
Borax, Commercial—	
Crystal	.. £25 per ton.
Powder	.. £26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	.. £5 17s. 6d. per ton d/d.
Copper Sulphate ..	.. £25 per ton.
Methylated Spirit 64 o.p.—	
Industrial ..	.. 2s. 7d.—2s. 11d. per gallon, according to quantity.
Mineralised ..	.. 3s. 8d.—4s. per gallon, according to quantity.
Nickel Sulphate .. / Nickel Ammon. Sulphate	.. } £38 per ton d/d. Normal business.
Potash Caustic ..	.. £30—£33 per ton.
Potass. Bichromate	.. 5¾d. per lb.
Potass. Chlorate ..	.. 3d.—4d. per lb.
Salammoniac ..	.. £32 per ton d/d.
Salt Cake	.. £3 10s. per ton d/d.
Soda Caustic, solid	.. Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals ..	.. £5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	.. £24 per ton.
Sod. Bicarbonate	.. £10 10s. per ton, carr. paid.
Sod. Bichromate ..	.. 4½d. per lb.
Sod. Bisulphite Powder 60/62%	.. £18—£19 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate ..	.. 3d. per lb.
Sod. Nitrate refd. 96% ..	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Sulphide conc. 60/65	About £14 10s. per ton d/d.
Sod. Sulphide cryst.	.. £9 per ton d/d.
Sod Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide— Golden	.. 5¾d.—1s. 4d. per lb., according to quality.
Antimony sulphide— Crimson ..	.. 1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic, Sulphide, Yellow	1s. 11d. per lb.
Barytes	.. £3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide	.. 3s. 9d.—4s. per lb., according to quantity.
Carbon Bisulphide	.. £30—£33 per ton, according to quantity. Again dearer.
Carbon Black ..	.. 7d.—7½d. per lb. ex wharf. Dearer.
Carbon Tetrachloride	.. £60—£65 per ton, according to quantity, drums extra. Again dearer.
Chromium Oxide, green ..	1s. 3d. per lb.
Indiarubber Substitutes White and Dark ..	{ 5d.—9½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black ..	.. £48 per ton, barrels free. Advanced.
Lead Hyposulphite	.. 7½d. per lb.
Lithopone, 30% ..	.. £22 10s. per ton.
Mineral Rubber "Rubpron"	.. £16 5s. per ton f.o.r. London.
Sulphur	.. £10—£12 per ton, according to quality.
Sulphur Precip. B.P.	.. £56—£57 per ton, according to quantity.
Sulphur Chloride	.. 4d. per lb., carboys extra. Dearer.
Thiocarbanilide ..	.. 2s. 6d. per lb.
Vermilion, pale or deep ..	5s. 1d. per lb. dearer.
Zinc Sulphide ..	.. 7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	.. £12 per ton.
Grey	.. £16 per ton.
Liquor	.. 9d. per gall. 32° Tw.
Charcoal	.. £7 15s.—£9 5s. per ton, according to grade and locality. Market brisker.
Iron Liquor ..	.. 1s. 7d. per gall. 32° Tw. 1s. 2d. " " 24° Tw.
Red Liquor ..	.. 10d.—1s. per gall. 14/15° Tw.
Wood Creosote ..	.. 2s. 9d. per gall. Unrefined.
Wood Naphtha—	
Miscible ..	.. 4s. 10d. per gall. 60% O.P.
Solvent ..	.. 5s. 3d. per gall. 40% O.P.
Wood Tar ..	.. £4 5s. per ton.
Brown Sugar of Lead	.. £43 per ton. Cheaper.

TAR PRODUCTS

Acid Carbolic—	
Crystals ..	.. 6½d. per lb. Quiet.
Crude 60's ..	.. 1s. 7d.—1s. 11d. per gall, according to district.
Acid Cresylic, 97/99	.. 2s.—2s. 1d. per gall. Demand fair.
Pale 95% ..	.. 1s. 9d.—2s. 1d. per gall. Not much enquiry.
Dark	.. 1s. 9d.—2s. 1d. per gall. Quiet.
Anthracene Paste 40% ..	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained ..	.. 7½d.—9d. per gall. Quiet.
Unstrained ..	.. 6½d.—7½d. per gall.

Benzole—	
Crude 65's	7½d.—9d. per gall. ex works in tank wagons.
Standard Motor	1s. 1½d.—1s. 3d. per gall. ex works in tank wagons.
Pure	1s. 5½d.—1s. 7d. per gall. ex works in tank wagons.
Toluole—90%	1s. 5d.—1s. 5½d. per gall. Small demand.
Pure	1s. 8d.—2s. per gall. Small demand.
Xylol coml.	2s. 3d. per gall.
Pure	3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	8½d. per gall. Better demand.
Middle Oil Heavy Oil Standard Specification	5d.—6½d. per gall., according to quality and district. Small export inquiry. Market quiet but fairly steady.
Naphtha—	
Solvent 90/160	11d.—1s. 2d. per gall., according to district. Steady market.
Solvent 90/100	11d.—1s. per gall. Not much demand.

Naphthalene Crude—

Market dull. Not much export inquiry. Cheaper in Yorkshire than Lancashire.

Drained Creosote Salts £4—£6. Quiet.

Whizzed or hot pressed £7—£9 per ton.

Naphthalene—	
Crystals and Flaked	£12—£13 per ton.
Pitch, medium soft	55s.—60s. per ton f.a.s. for next season. Frequent inquiries.
Pyridine—90/160	19s. per gall. Steady demand.
Heavy	12s. per gall. Market dull.

INTERMEDIATES AND DYES

There has been some slight improvement in the business passing for Aniline Dyes.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 7d. per lb.
Acid H.	3s. 11d. per lb. 100% basis d/d.
Acid Naphthionic	2s. 2d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 1d. per lb. Improved demand.
Acid Sulphanilic	9½d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	8d. per lb. naked at works.
Aniline Salts	8½d. per lb., naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 1d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 19/31° C.	4½d. per lb. Rather quiet.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline	3s. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£85 per ton.
Diethylaniline	4s. 6d. per lb. d/d., packages extra, returnable.
Dimethylaniline	2s. 3d. per lb. d/d. Drums extra.
Dinitrobenzene	9d.—10d. per lb. naked at works.
Dinitrochlorbenzol	£84 10s. per ton d/d.
Dinitrotoluene—48/50° C.	8d.—9d. per lb. naked at works.
66/68° C.	1s. 2d. per lb. naked at works.
Diphenylamine	2s. 10d. per lb. d/d.
Monochlorbenzol	£63 per ton.
βNaphthol	1s. per lb. d/d.
αNaphthylamine	1s. 4d. per lb. d/d.
βNaphthylamine	4s. per lb. d/d.
m-Nitraniline	4s. 3d. per lb. d/d.
p-Nitraniline	2s. 3d. per lb. d/d.
Nitrobenzene	5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. 11d. per lb. 100% basis d/d.
Nitronaphthalene	10½d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	3s. 11d. per lb. d/d.
p-Phenylene Diamine	10s. 2d. per lb. 100% basis d/d.
R. Salt	2s. 5d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 3d. per lb. 100% basis d/d.
o-Toluidine	8½d. per lb.
p-Toluidine	3s. 3d.—4s. 2d. per lb. naked at works.
m-Toluylene Diamine	4s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	£45 per ton.
Acid, Acetyl Salicylic	3s. 1d.—3s. 3d. per lb., according to quantity.
Acid, Benzoic B.P.	3s. per lb.
Acid Boric B.P.	Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	19s.—21s. per lb.
Acid, Citric	1s. 4½d.—1s. 5d. per lb., less 5% for ton lots. Market very weak.
Acid, Gallic	3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst.	6s. 9d. per lb. Resublimed quality 8s. per lb. Market firm; increasing demand.
Acid, Salicylic	1s. 5d.—1s. 8d. per lb., according to quantity.
Acid, Tannic B.P.	2s. 10d. per lb. Market quiet.
Acid, Tartaric	1s. 1½d. per lb. less 5%.
Amidol	9s. per lb. d/d.
Acetanilide	2s. 1d.—2s. 3d. per lb. for quantity. Demand slow.
Amidopyrin	13s. 3d. per lb. Neglected. Stocks low.
Ammon. Benzoate	3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	12s. 6d. per oz. for English make.
Barbitone	15s.—15s. 6d. per lb. Quiet market.
Benzonaphthol	5s. 3d. per lb. Small inquiry.
Bismuth Salts	Prices reduced by about 1s. 3d.—2s. 3d. per lb. on account of the fall in the price of the metal.
Bismuth Carbonate	10s. 6d.—12s. 6d. per lb.
„ Citrate	10s. 3d.—12s. 3d. „
„ Salicylate	9s.—11s. „
„ Subnitrate	8s. 8d.—10s. 8d. „
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides	Market firm, and Continental prices fully maintained with upward tendency.
Ammonium	1s. 6d.—1s. 9d. per lb.
Potassium	1s. 4d.—1s. 7d. per lb.
Sodium	1s. 5d.—1s. 8d. per lb.
Calcium Lactate	1s. 5d.—1s. 9d., according to quantity. Fair demand and steady market.
Chloral Hydrate	4s.—4s. 3d. per lb. Very firm and scarce.
Chloroform	2s. per lb. for cwt. lots. Very steady.
Creosote Carbonate	6s. 6d. per lb. Little demand.
Formaldehyde	£59 per ton.
Glycerophosphates—	Fair business passing.
Calcium, soluble and citrate free	7s. per lb.

Glycerophosphates—	
Iron	8s. 9d. per lb.
Magnesium	9s. per lb.
Potassium, 50%	3s. 6d. per lb.
Sodium, 50%	2s. 6d. ,,
Guaiacol Carbonate	10s. 6d.—11s. 3d. per lb.
Hexamine	3s. 1d. per lb. and upwards. Market weaker.
Homatropine Hydrobromide	30s. per oz.
Hydrastine hydrochlor	English make offered, 120s. per oz.
Hypophosphites—	
Calcium	3s. 6d. per lb., for 28-lb. lots.
Potassium	4s. 1d. per lb.
Sodium	4s. ,,
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 5d. per lb.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£75 per ton, less 2½%.
Heavy Commercial	£25 per ton, less 2½%. Price reduced.
Heavy Pure	2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	56s. per lb.
Synthetic	26s.—31s. per lb., according to quantity. English make.
Mercurials	Market very quiet.
Red oxide	5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	3s. 6d.—3s. 7d. ,,
White precip.	4s. 7d.—4s. 8d. ,,
Calomel	3s. 11d.—4s. ,,
Methyl Salicylate	1s. 9d.—1s. 10d. per lb. Market has weakened.
Methyl Sulphonal	26s. per lb.
Metol	11s. per lb. British make.
Paraformaldehyde	2s. 10½d.—3s. per lb. Not very active.
Paraldehyde	1s. 6d. per lb. in free bottles and cases.
Phenacetin	5s. 9d. per lb.
Phenazone	7s. 2d. per lb.
Phenolphthalein	5s. 7d. per lb. in cwt. lots.
Potass. Bitartrate—	
99/100% (Cream of Tartar)	88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate	1s. 10d.—2s. 2d. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Steady market.
Potass. Metabisulphite	7½d. per lb., 1-cwt. kegs included. F.o.r. London.
Potass. Permanganate	7¾d. per lb.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	5s. 6d. per lb.
Saccharin	63s. per lb., in 50-lb. lots.
Salol	3s. 6d. per lb.
Silver Proteinate	9s. 6d. per lb.
Sod. Benzoate, B.P.	2s. 6d. per lb. Ample supplies. B.P. quality available.
Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity.
Sod. Hyposulphite—	
Photographic	£13—£1[illegible] per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	16s. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	75s.—82s. 6d. per cwt., according to quantity. Quiet market.
Sod. Salicylate	Market rather easier. Powder 2s. 1d.—2s. 3d. per lb. Crystal at 2s. 3d.—2s. 5d. per lb. Flake 2s. 9d. per lb.
Sod. Sulphide—	
Pure recryst.	10d.—1s. 2d. per lb.
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Sulphonal	15s. per lb. Easier.
Thymol	17s. 6d. per lb. Very scarce indeed.

PERFUMERY CHEMICALS

Acetophenone	12s. 6d. per lb.	
Aubepine	15s. 3d. ,,	
Amyl Acetate	2s. 6d. ,,	
Amyl Butyrate	6s. 9d. ,,	
Amyl Salicylate	3s. ,,	
Anethol (M.P. 21/22° C.)	4s. 6d. ,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 9d. ,,	
Benzyl Alcohol free from Chlorine	2s. 9d. ,,	
Benzaldehyde free from Chlorine	3s. 6d. ,,	
Benzyl Benzoate	3s. 6d. ,,	
Cinnamic Aldehyde—		
Natural	18s. 9d. ,,	
Coumarin	19s. 6d. ,,	
Citronellol	17s. ,,	
Citral	8s. 6d. ,,	
Ethyl Cinnamate	12s. 6d. ,,	
Ethyl Phthalate	3s. 3d. ,,	
Eugenol	10s. 6d. ,,	
Geraniol (Palmarosa)	35s. ,,	
Geraniol	11s.—18s. 6d. per lb.	
Heliotropine	6s. 9d. ,,	Cheaper.
Iso Eugenol	15s. 9d. ,,	
Linalol ex Bois de Rose	26s. ,,	
Linalyl Acetate	26s. ,,	
Methyl Anthranilate	9s. 6d. ,,	
Methyl Benzoate	5s. ,,	
Musk Ambrette	45s. ,,	
Musk Xylol	13s. 6d. ,,	Cheaper.
Nerolin	4s. 9d. ,,	
Phenyl Ethyl Acetate	15s. ,,	
Phenyl Ethyl Alcohol	16s. ,,	
Rhodinol	60s. ,,	
Safrol	1s. 10d. ,,	
Terpineol	2s. 4d. ,,	
Vanillin	26s. per lb.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	15s. 6d. per lb.
Anise Oil	2s. 8d. per lb.
Bergamot Oil	17s. 6d. per lb.
Bourbon Geranium Oil	36s. 0d. per lb.
Camphor Oil	65s. per cwt.
Cananga Oil Java	10s. 6d. per lb.
Cinnamon Oil, Leaf	6½d. per oz.
Cassia Oil, 80/85%	10s. per lb.
Citronella Oil—	
Java 85/90%	5s. 9d. per lb.
Ceylon	3s. 7d. per lb.
Clove Oil	7s. 6d. per lb.
Eucalyptus Oil 70/75%	2s. 3d. per lb. Cheaper.
Lavender Oil—	
French 38/40% Esters	27s. 6d. per lb

Lemon Oil	..	.. 3s. per lb.
Lemongrass Oil	..	.. 4s. 6d. per lb.
Orange Oil, Sweet		... 11s. per lb.
Otto of Rose Oil—		
Bulgarian	..	.. 37s. 6d. per oz. Production below average.
Anatolian	..	.. 18s. per oz.
Palma Rosa Oil	..	.. 16s. 6d. per lb. Cheaper.
Peppermint Oil—		
Wayne County		.. 30s. per lb. Market very active.
Japanese	..	.. 18s. 6d. per lb. Market very active and prices rising.
Petitgrain Oil	..	.. 9s. 3d. per lb.
Sandal Wood Oil—		
Mysore ..	..	.. 26s. 7d. per lb.
Australian	..	.. 21s. per lb.

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before Nov. 17th; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on October 2nd.

I.—Applications

Barker. Filtering-apparatus. 21,331. Sep. 9.

Blakeley. 21,552. *See* II.

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number :—*Australia* : Glassware (301) ; Steel (Official Secretary, Commercial Bureau, Australia House, Strand, London, W.C. 2, Ref. 412/7/1/1/287) ; *Brazil* : Paints (B.X./1170) ; *British India* : Steel (Director General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E. 1) ; *Netherlands* : Ironware, iron (314), cutlery (315) ; *New Zealand* : Scientific instruments (B.X. 1236) ; *South Africa* : Agricultural implements, fertilisers (306).

Glue and Gelatin Output in the United States, 1923

The Department of Commerce, Washington, announces that, according to data collected in the biennial census of manufacturers, 1923, the fifty establishments engaged primarily in the manufacture of glue and gelatin reported products valued at $24,366,097, an increase of 14·2 per cent. as compared with 1921, the last preceding census year. In addition glue and gelatin are manufactured to a considerable extent as secondary products by establishments engaged primarily in other industries, principally slaughtering and meat packing and the manufacture of fertiliser. The value of these commodities thus produced outside the industry proper in 1921 was $4,277,256, an amount equal to 20 per cent. of the total value of products reported for the industry as classified. The corresponding value for 1923 has not yet been ascertained, but will be shown in the final reports of the present census. The statistics for 1923 and 1921 are summarised in the following statement, the figures for 1921 being given in brackets : Number of establishments, 50 (47) ; wage earners, average number, 3651 (2915) ; wages, $4,075,904 ($3,573,149) ; cost of materials (including fuel and containers), $14,590,638 ($13,401,858) ; products, total value, $24,366,097 ($21,342,004) ; fish glue, $2,355,041 ($1,693,946) ; animal glue, $13,702,570 and glue (other than fish or animal), $4,633,829 ($13,433,718) ; all other products, $3,674,567 ($6,214,340) ; value added by manufacture, $9,775,459 ($7,940,146).—(*Oil, Paint and Drug Rep., Sept.* 8, 1924.)

MESSRS. J. & A. CHURCHILL announce that they have in the press, and hope to publish early in 1925, a "Dictionary of Perfumery," by Ernest J. Parry, B.Sc. The work will be in two volumes, and will deal with the raw materials of the perfumery trade and with allied subjects from the points of view of the chemist, the manufacturer and the user. Special articles, which will appear over the writers' signatures, have been contributed by Messrs. A. C. Marrin, C. T. Bennett, B.Sc., T. H. Durrans, M.Sc., M. Dewhirst, B.Sc., A. Garden, B.Sc., M. Salamon, B.Sc., and W. H. Simmons, B.Sc.

JOURNAL of THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council of Pure and Applied Chemistry

which consists of Representatives from

The Chemical Society, the Society of Chemical Industry, the Association of British Chemical Manufacturers, the Institute of Chemistry, the Society of Public Analysts, the Faraday Society, the Institute of Brewing, the Society of Dyers and Colourists, the Society of Glass Technology, the Iron and Steel Institute, the Ceramic Society, the Institution of Gas Engineers, the Society of Leather Trade Chemists, the Royal Photographic Society, the Mineralogical Society, the Biochemical Society, the Institute of Metals, and the Royal Agricultural Society.

VOL. 43 NEW SERIES | LONDON, AUGUST 1, 1924 | NO. 31

EDITORIAL

WE notice in *Industrial and Engineering Chemistry* for July a letter from Prof. Noyes in which he alludes to his article on a "Political Platform for the International Union of Pure and Applied Chemistry," and to our editorial comments on this topic. He claims to detect a change in our opinions on this matter; we do not attach any importance to our opinions, the chemical world will not be diverted from its ordained path by any utterances on our part, our editorial effusions do not represent the considered judgments of the Society of Chemical Industry nor those of the Federal Council. As our correspondent Mr. Williams points out in this week's issue, chemists are human beings and cannot divest themselves of their humanity or inhumanity however much chemistry is absorbed by them or adheres to them. We do not think our opinions are worthy of the publicity which Prof. Noyes has given to them, but as a matter of fact we are not conscious of any change in them. The question is an important one, however trivial may be our individual views. Our previous editorials have dealt with two aspects of the problem. The first, only briefly and casually referred to, the origin and conduct of the war, we do not consider to be suitable for discussion in these columns. We are all of us entitled to our own opinions on this matter and we shall have them whether we are entitled to them or not. Prof. Noyes as an American will doubtless accept this well-known American dictum. Our opinion on this matter we think remains as strong as it was and is not likely to alter. The other aspect is the policy to be adopted by the Union Internationale; there is no doubt that this is undergoing or has undergone a change. We have on more than one occasion stated that in our opinion this is of more consequence to our French and Belgian allies than to British chemists, and we have mildly hinted that we should neither urge nor advise the French and Belgian chemists to adopt any particular course. We venture to think that neither the British nor the American chemists are likely to influence French and Belgian chemists in this matter. If our allies feel bitter they will not diminish their bitterness because the British and Americans feel less bitter. If our allies on the other hand are disposed to welcome chemists of all nations to the Union Internationale they will do this when they themselves feel disposed and not when we feel disposed. In our consideration of this particular problem we are ignoring entirely the future relations between the various European countries, we put on one side invasions and occupations, defaults, loans and reparations, these are not the concern of the Union Internationale; individual chemists may think what they please and advocate what they please about these; in their corporate capacity as members of the Union they should consider what is the policy which will be of the greatest benefit to the Union. We are not, of course, claiming that the French and Belgians are to be the sole judges of the future of the Union; we are merely claiming that at the present time and in view of what has been discussed and the temper in which the discussion has taken place the most prudent and sensible course is for the British and American chemists to leave the problem alone for a while and that so far as chemical journals are concerned the less we discuss in them the causes of the lack of confidence on both the French and German sides the less likely are we to make statements which will hinder the future prosperity of the Union Internationale.

* * *

It was our intention, until to-day, to deal this week with the chemistry of Yadil, but as we see from the daily press that the proprietors of that antiseptic mixture have issued a writ for libel against the *Daily Mail*, Sir William Pope and Professor Dixon, we are compelled to hold over this

interesting topic. We have no wish to be guilty of contempt of court in discussing proceedings which will be left for the courts to determine, nor do we think that the Society of Chemical Industry would be extremely grateful for the opportunity of indulging in litigation itself while other people are willing to cultivate this exciting and pleasing hobby. It seems to be common ground to both plaintiffs and defendants that formaldehyde and oil of garlic are essential to the manufacture of Yadil Sir William Pope gave an approximate estimate of the percentage of oil of garlic ; the proprietors of Yadil in a communication to the daily press are more precise, they say "roughly one ounce of oil of garlic to every 5481 ounces of Yadil." No doubt when the case comes to trial we shall have this proportion not "roughly" but with a degree of precision represented by three or four more places of decimals. It is well to be precise when dealing with figures : it is not only scientific but is also impressive Many a limited company shows its book debts to the exact penny, say an accuracy of one part in two hundred millions, while it over-estimates its stock or goodwill by fifty or seventy-five per cent. The proprietors of Yadil claim that they make use, not of the injurious formaldehyde, but of the innocuous paraformaldehyde or trioxymethylene, which they call trimethanal. We have but little acquaintance with this latter substance : according to Richter it is distinguished by its insolubility in water, alcohol and ether. We suppose it is more soluble in a dilute solution of glycerine but this also is a matter for the courts. An agreeable vista of examination, cross-examination and re-examination is opened to us whereby chemical knowledge will be increased.

*   *   *

This week has opened with one of those announcements that cause chemists to refer to back numbers of *Chemistry and Industry* and prepare poison gases. Such an announcement could have to do with but a few subjects, and of those, what more prolific of discussion than the utilisation of coal ? An official statement has been issued to the daily press, according to which the Mines Department and the Department of Scientific and Industrial Research have been giving "careful attention to the best means of using the national coal resources," and it seems to have been discovered that "at the back of all is the problem of how best to unlock the heat in the coal" At the instance of the two departments, so the statement runs, the Government has decided to provide at once for the rapid development of the chemical and physical survey of the coal seams with a view to the best use of the national coal resources. In addition, it is intended to encourage all promising new processes for the carbonisation of coal at low temperatures, which have reached the stage of commercial production. Provision will thus be made for the establishment of more of the local committees of coal owners and technical experts which have already done much valuable work in classifying the coal seams by means of physical and chemical tests. Further, "as it is evident that the technical problems of carbonising coal at low temperatures have been solved, but that before we can safely introduce the process with a prospect of financial success, further large-scale work—mainly on engineering problems—remains to be done," the scheme offers, on the engineering side, the assistance, at the cost of public funds, of the Fuel Research Station in the examination of promising processes under conditions which will shortly be made public.

*   *   *

It is, of course, highly desirable that we should possess full information on the extent and characters of our coal resources. More ample knowledge of this kind would prevent much waste and it should in time lead to the purchase of coal on the basis of analysis, as well as to the proper utilisation of the lower grades, too often wasted. Indeed, the object of the offer of assistance to processes for low-temperature carbonisation is largely to facilitate the use of the lower-grade coals for the production of smokeless fuel and of fuel oils. In these columns we have from time to time commented on various aspects of the fuel problem, we have toyed in our sanctum with dreams of cloudless untainted skies, we have waxed enthusiastic over various developments that promise solutions. In a thick and cloudy air, said an old writer, men are sad and peevish ; and if the Western winds blow and that there be a calm or a fair sunshine day, there is a kind of alacrity in men's minds ; it cheers up men and beasts ; but if it be a turbulent, cloudy, stormy weather, men are sad, lumpish, angry, dull, and melancholy. But it was also pleaded that "fire and smoke qualify the air," and it was supposed that "a thick foggy air helps the memory, as in them of Pisa in Italy." Nowadays, we know full well the benefits of pure air, but in respect of the carbonisation of coal we have as many opinions as had the men of old about air. The gas industry has strong ideas on the subject and one may expect some highly interesting encounters. It is not likely that any one solution will appeal to all coal users or proprietors, but we are assured that the attempt is to be made to solve the problem on a scale of national importance, for "only in this way can any ultimate effect on the state of employment and the industrial prosperity of the country be produced" This is no time for destructive criticism. There are ample signs, as our correspondence columns bear witness, that there is a growing uneasiness at the continued waste of coal. We are hopeful that the murmured "something is going to be done" will now be transformed into an actual accomplishment. Many of the data are collected, the scientific knowledge of coal and its problems has grown amazingly, low-temperature carbonisation is being applied in Nottingham, and the Government is now giving a hand. Manchester is no doubt already calculating the saving that will result, and Sheffield may look skywards uneasily, foreboding the disappearance of its familiar pall. And if Sir George Beilby looks out into the future through the mist and wet of what should be a brilliant July morning, he must indeed be a happy man.

THE THEORY OF THE "BENSON" SUPER-PRESSURE STEAM GENERATOR

(From a Correspondent)

It will not be without interest, following upon a previous article in *Chemistry and Industry* (March 7), to consider a little more in detail the scientific principles underlying the design of the remarkable "Benson" super-pressure steam generator, in which water is converted into steam without the absorption of latent heat under the critical conditions of approximately 3200 lb. pressure per sq. inch and a temperature of 706° F. (375° C.).

As will be remembered, the installation consists of a series of coils of $\frac{3}{4}$ in. steel tubing arranged vertically, through which distilled water is being passed continuously at 3200 lb. pressure by means of a gear-driven force pump. The coils are heated by an oil or pulverised-fuel flame blast, using hot air for combustion, and towards the end of the travel the water attains a temperature of 706° F. (375° C.), and is bodily converted into steam without ebullition or boiling, and therefore without the absorption of latent heat. The steam is then discharged at a slight superheat 720° F. (385° C.) through a reducing valve, being thereby reduced in temperature to about 620° F. (330° C.), and into a second series of coils forming a superheater, in which it is heated to an average of 850° F. (455° C.), and finally discharged at this temperature and 1500 lb. pressure to the turbine or other source of use.

The essential reason underlying the design of the "Benson" generator and the employment of 3200 lb. pressure is to obtain on a practical scale very high pressure steam with the aid of the coil generator or "boiler." The elimination of latent heat in itself does not result in any higher efficiency in the condensing turbine, the heat being of course lost in the condenser just the same. That is to say, the increase in theoretical efficiency to be obtained by using steam at 3200 lb. pressure, as compared with say 2750 lb., is very small. The practical difference, however, is enormous, because in the first case no latent heat of steam is required and a coil generator can be used, whereas in the second case the latent heat of steam is about 290 B.Th.U. (from 1 lb. of water at 32° F.), so that ebullition or boiling accompanies the generation of the steam, and a coil generator consequently is not practicable.

The main difficulty with the use of high-pressure steam has always been to construct a boiler to stand the conditions, and 127 years of evolution—since 1797 when Richard Trevithick invented the "Cornish" boiler, worked at 25 lb. pressure—has only resulted in the average industrial steam pressure being to-day, say, 100—160 lb., ordinary power station pressures 160—220 lb., and the modern super-power station 350 lb. Whilst a few water-tube boilers are now constructed to work up to about 600 lb. and even 800—1200 lb. as an experiment, for several thousand pounds pressure it is necessary to use narrow bore coils to reduce the area that has to stand the strain, and incidentally also to eliminate the element of danger by having an extremely small water content. A steel tube can be constructed to stand thousands of lbs. per square inch pressure, and the present "Benson" generator was put on hydraulic test by the insurance company to 6400 lb. per square inch for twenty minutes without a trace of leakage.

But the absorption of latent heat has hitherto proved an insurmountable obstacle to the use of the coil generator, because particles of liquid (water) are converted into comparatively large bubbles of gas (steam) of much greater volume, so that in a narrow bore coil the whole water contents are blown out. Mr. Benson has solved this problem by a thorough consideration of the properties of steam. As the pressure rises, the latent heat, which is 966·6 units under atmospheric conditions, diminishes, since the change in volume between water and steam becomes less and less. The ordinary steam tables do not show this as they seldom go above 250 lb. pressure, and it is necessary to study some publication such as Goodenough's "Properties of Steam and Ammonia" (John Wiley or Chapman and Hall). The following typical figures illustrate the reduction in the latent heat as the pressure rises :—

(1 lb. Water at 32° F.)

Absolute pressure, lb. per sq. in.	Saturated Steam Temperature, ° F.	Sensible heat from 32° F.	Latent heat B.Th.U.
114·9	338	308·5	882·2
361·6	435	411·4	791·2
538·7	475	455	745·8
1093·0	550	544	644·8
1785	620	633	518
2369	660	700	412
2880	690	770	280
3075	700	820	198
3206	706·3	924	Nil

Mr. Benson has therefore completely solved the problem by going right up to the critical conditions when no latent heat at all is required, since the steam is at the same volume as the water (three times that of 60° F.), and therefore no ebullition takes place. Once steam is formed, and what is the essential difference between a liquid and a gas is outside the scope of this article, then we can do what we like in the way of superheating or reducing the pressure.

To calculate the amount of the increase in thermal efficiency by raising the steam pressure to 1500 lb. or over is a complicated question, and it is best obtained from a series of Rankine cycles plotted for different pressures at constant total heat of steam on temperature entropy diagrams, both of course under adibatic (or theoretically perfect) expansions. Thus taking a total heat of steam at 1350 B.Th.U. calculated from 32° F., and superheating as required to attain the given total heat, at 100 lb. pressure only 400 B.ThU. (29·6 per cent.) is theoretically available for actual work in expanding down to a vacuum (29 in.), whereas at 350 lb. the figure is 468 B.Th.U. (34·7 per cent.), and at 3200 lb. 595 B.Th.U. (44·0 per cent.).

Practically, of course, there is a considerable loss for various reasons, but the matter can be concisely expressed by saying that the ordinary high-class industrial steam engine or turbine is running at 10—11 per cent. thermal efficiency from the coal, the most modern super-power station 17—19 per cent. (an exceptional figure), whereas a large

"Benson" generator plant would give 28—30 per cent., an amazing advance. In other words, we can now generate power from raw coal, using a condensing unit and pulverised fuel for heating, at an efficiency equal to the Diesel engine with oil, and the principle is equally revolutionary applied to land, marine, locomotive and motor-car work. In addition, the use of the exhaust steam from the turbine in boiling and process work, as in the chemical industries, would apparently give an over-all thermal efficiency of something like 80—85 per cent. since no heat is lost in the condenser.

THE FATTY ACID MOLECULE

By T. W. JONES, B.Sc.

Examination of the fatty acids, their salts and esters by the method of X-ray analysis has but confirmed the correctness of the structures already ascribed to them on purely chemical reasoning. The long rectilinear CH_2-chain formation of these compounds has long been accepted on theoretical grounds. Direct experimental proof, we know, has a satisfaction not possessed by any theory, however plausibly it may fit the facts. Langmuir and Adams gave us a clear picture of the results of spreading oil on water, and that the fatty acid molecule then stood on its head so to speak, the COOH group in the water and the rest of the chain erected vertically. The clue to another line of experiment was given by Friedel's hypothesis of a meso-morphic state of matter; a sort of half-way house between the crystalline and amorphous conditions. In this state, matter may be in two phases, the nematic and the smectic. Among the bodies said to assume the smectic phase on solidification are the soaps; these are optically positive, possess a high viscosity and are quite rigid except in the direction of their optical axis. They should, therefore, consist of a regular formation of equi-distant molecular layers and be capable of diffracting X-rays in a manner similar to that of the reticular parallel planes of a crystal system.

The correctness of this hypothesis was proved by M. Friedel and le duc de Broglie (*Comptes Rendus*, 1923), and they found, in the X-ray spectrum from the cleavage plane of a lamina of sodium oleate, a predominant line corresponding to a spacing of 40 A.U. between two homologous points of two successive layers of the lamina. They formed the opinion that the long CH_2-chains of the sodium oleate molecules were arranged parallel to the optical axis and that the spacing was at least equal to the length of these chains and large compared to the atomic distances.

Messrs. Piper and Grindley in their X-ray examination of the fibres so often observed in soap curds, obtained (*Proc. Phys. Soc. Lond.*, 1923 **35**, 269) lines corresponding to spacings of 33·5 A.U., 38·5 A.U., and 43·5 A.U. for the sodium salts of lauric, myristic and palmitic acids respectively. These spacings are of the same order as that obtained by the two previous workers for sodium-oleate curd. In addition they show a regular increase in length with the increase of the CH_2-chain of the acid. Muller and Shearer (*J.C.S.*, 1923, **123**, 2043 and 3156) obtained spacings of the same order, and showing a uniform increase with increase in the CH_2-chain, from their examination of the pure saturated fatty acids. Shearer, in his work on the esters of the fatty acids (*J.C.S.*, 1923, **123**, 3152), observed spacings concordant with each other, but considerably smaller than those found for the acids themselves, or for their sodium salts. For example his figures for the esters of palmitic and stearic acids were:—

Methyl palmitate 22 A.U. Methyl stearate 24·0 A.U.
Ethyl ,, 23·2 A.U. Ethyl ,, 25·2 A.U.

whilst Muller's figures for free palmitic and stearic acids were 34·7 A.U. and 38·7 A.U. respectively. Shearer's figures also bring out the regular increase of the spacing with increase of the ester CH_2 chain both on the acid side and the ester side of the COO-group.

In addition to these lines corresponding to the wide spacing all the investigators have found in each spectrum observed two other lines corresponding to spacings in the laminae of the order 4 A.U. Thus Piper and Grindley observed spacings of 4·9 A.U. and 4·2 A.U. for the sodium salts examined. These were constant, *i.e.*, they did not vary for the different salts. Shearer and Muller found similar spacings of 3·7 A.U. and 4·1 A.U. respectively, which were constant for all the acids and esters examined. These shorter spacings, it would appear, correspond to the cross-section of the unit cell of these smectic bodies, as the longer spacing corresponds to their length. The unit cell would appear, therefore, to be a long prism of the same effective cross-section for all the acids, esters and sodium salts examined, and containing one or more molecules, as we shall presently see. According to Piper and Grindley the rectangular shape of the cross-section can be accounted for on the accepted distribution of the COOH-group as being

$$\begin{array}{c}C\text{-}O\text{-}H\\ \|\\ O\end{array}$$

and it is quite conceivable that a group so distributed would have an effective width in its plane greater than in a direction at right angles to it.

The constancy of these narrow spacings as compared with the variability of the larger spacing with changes in the number of carbon atoms in the chain agrees with the chemical view that additional CH_2-groups increase the fatty acid molecule in one direction only. As the X-ray spectrometer only measures the perpendicular distance between two *identical* planes of the crystal, it is probable that the spacing of any plane will have in general only an approximate connexion with the actual molecular dimensions. That this is so is obvious from a comparison of these observed spacings and the dimensions for the molecule given by Langmuir (*J. Amer. C. S.*, 1917, 39, 1865). His value for the length of the palmitic acid molecule is 24 A.U., whilst Muller's observed spacing is 34·7 A.U. The latter figure is too great to allow of the unit cell containing one such molecule and too small for two. Again, taking

the accepted diameter of the carbon atom (1·5 A.U.) and calculating the length of a palmitic-acid molecule in which the carbon atoms are piled upon top of one another, we obtain a figure widely different from Muller's value. It is, however, possible to imagine the unit cell as containing two molecules if these are shortened in length by the adoption of a zig-zag configuration of the CH_2-chain. Such an arrangement of two molecules to a cell is a very common one in crystal structure. On the assumption that the carbon atoms are arranged in a zig-zag pattern, it is possible to calculate the angle θ between successive pairs

sin $\theta/_2$=1·5/4·22 or θ 109°30′, which is almost exactly the angle 109°28′ which the normals from the centre to the faces of a tetrahedron make with one another. The configuration adopted must, therefore, permit this angle between successive carbon atoms and must, moreover, give the observed increase with each additional carbon atom.

Shearer (*ibid*) finds an increase of 1·22 A.U. for each extra CH_2-group in the ester chains, whilst Muller finds with the acids an increase of 2·0 A.U. for each increase of two carbon atoms. Of this 2·0 A.U. one carbon contributes, he thinks, 1·5 A.U. and the other 0·5 A.U. Evidence, therefore, points to the existence of two types of chains. The first, which would apply to the esters, would be an ordinary zig-zag in which the angle between successive carbon atoms would be 109°30′. This gives an increase of 1·22 A.U. for each extra CH_2-group. In the other the carbon atoms are arranged in a spiral formation in sets of four, the fifth being directly over the first: each set of four need not, however, be in the same plane as the preceding four. In such a configuration each additional two CH_2-groups contribute 2·0 A.U. to the length of the chain, one of them adding 1·5 A.U. and the other 0·5 A.U. This would agree with the results found for the acids and sodium salts.

Both these types of increase are found in the diamond structure, which, in addition to the closed rings, comprises chains showing increases of 1·22 A.U. for each carbon atom increase and 2·0 for each increase of two carbon atoms.

If the configuration of the acids is as suggested, there should be a difference in the experimental results from odd and even acids of the same series. The difference, however, is as yet unascertainable, as it lies within the range of present experimental error. But it is a significant fact that if the spacings of the odd acids are plotted on a diagram, similar to that used to represent the increase in the spacing of the even acids against the increase in the CH_2-chain, the points representing them lie just above the line of the even acids. This is in accord with the theory put forward by Garner and Randall (*J.C.S.*, 1924, **124**, 881) to explain the existence of the two enantiotropic forms of the odd acids. They find that the sum of the heat of transition of the α-form of the odd acids of a series into the β-form and the heat of crystallisation of the α-form correspond approximately with the heat of crystallisation of the β-form. Also the heats of crystallisation of the α-form of the even acids and the β-form of the odd acids lie very nearly on a smooth curve, and it is therefore suggested that the two forms have a similar constitution in the solid state and give the acids the following configurations:—

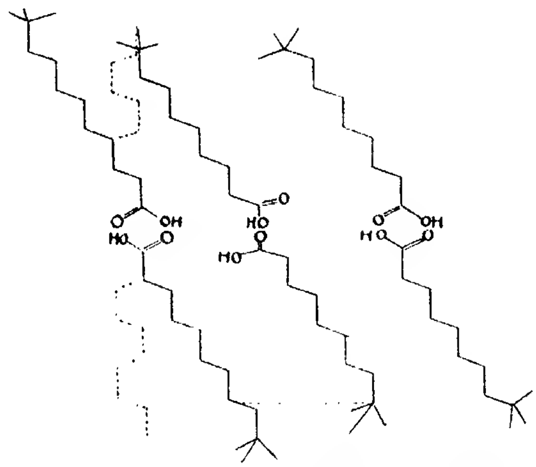

FIG. I α-Even FIG. II α-Odd FIG. III β-Odd

It is obvious that the carboxyl groups play an important part in this alternation, and it is possible that this group is orientated in two different ways, in the odd and even acids. The symmetrical forms of Figs. 1 and 2 would be formed with a larger amount of heat as required by experiment.

In the acids and sodium salts the molecules would, by reason of the affinity of the CH_3 groups for each other, orientate themselves with these groups in contact inwards. The planes containing the sodium atoms would, therefore, be the planes of slip required by Friedel's theory. The exact conformation of the diagrams given by Randall and Garner are slightly different from those shown by Muller and Shearer (dotted lines), but they agree equally well with the dimensions experimentally found. Furthermore, they bring out more clearly than the latter the fact that the general direction of the length of the molecule need not necessarily be perpendicular to the cleavage plane, although to account for the uniform increase in spacing of this plane for each additional CH_2-group, it must be supposed that the molecules of any one series are all inclined at the same angle to this plane.

From considerations of the shortness of the long spacings and the fact that an additional CH_2-group gives an increase of half that found for the same increase in the acids, it appears that the esters contain but one molecule per unit cell. That the molecule does not bend at the COO-group but continues in the same direction is borne out by the fact that increases in either acid or ester chain result equally in a lengthening of the spacing. So that the X-rays measure the distance between the COO-

groups and the molecules are arranged as :—

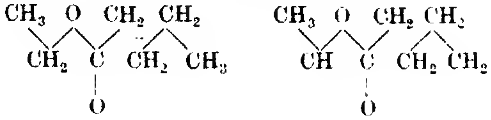

Fig. IV

Measurements of the spacings of ring-chain compounds such as *p*-hexadecyl-phenol and *p*-octadecyl-phenol indicate a similar uniform increase for additional CH_2-groups, but the experimental accuracy is not sufficient to permit a definite statement as to the type of chain present.

From evidence gained from the unsaturated acids elaidic and brassidic it seems probable that a fuller examination will but confirm chemical theories of the nature of the unsaturated linkages. For example, the wide spacing of elaidic acid, stereo-isomeric with oleic acid, is about 9 A U longer than that of stearic acid, which contains the same number (18) of carbon atoms. The smaller spacings corresponding to the cross-section of the cell are, however, the same as those already found for the saturated acids.

BRITISH CAST-IRON RESEARCH ASSOCIATION LABORATORIES

A further stage in the development of the Cast Iron Research Association was reached a few days ago when the Association formally took possession of its own Laboratories, situated in Guidford Street, Birmingham, and equipped for the conduct of chemical analyses and general metallurgical and heat-treatment work. The capacity of the Association to deal with its work will be greatly increased, but it is not intended to abandon the policy of having investigations conducted in prominent University laboratories and in the works of members.

It is anticipated that the Association, which commenced a new financial year on July 1, will incur an expenditure during the year of between £6000 and £7000. The research programme includes important investigations on erosion- and corrosion-resisting cast irons; moulding sands; graphitisation heat-resisting cast iron; the production of malleable cast iron; cupola practice; cast irons for electrical and magnetic purposes: measurement of melting and pouring temperatures; the fundamental properties of cast iron; standardisation of test bars, materials and methods; facing sands and backings, and cast iron to resist abrasive wear, and jointly with the British Motor and Allied Manufacturers Research Association, automobile cylinders and pistons.

Recent new members include the Brightside Foundry and Engineering Co., Ltd., Sheffield; Powell Duffryn Steam Coal Co., Ltd., Glamorgan; Boving Engineering Works, Ltd., Stoke-on-Trent; J. Blakeborough and Sons, Ltd., Brighouse, Yorks; J. W. Jackman and Co., Ltd., Manchester, and Younger and Gallon, Dunston-on-Tyne.

FORTHCOMING EVENTS

Sept. 4 and 5. Iron and Steel Institute, Autumn Meeting at British Empire Exhibition, at 10.30 a.m. each day. (1) "Changes of Volume of Steels During Heat Treatment," by L. Aitchison and G. R. Woodvine. (2) "Investigations on the Herbert Pendulum Hardness Tester," by C. Benedicks and V. Christiansen. (3) "Effect of Changes in Total Carbon and in the Condition of Carbides on the Specific Resistance and on some Magnetic Properties of Steel," by E. D. Campbell and G. W. Whitney. (4) "Pickling: The Action of Acid on Iron and Steel, and the Diffusion of Hydrogen Through the Metal," by C. A. Edwards. (5) "Examination of Iron from Konarak," by J. N. Friend and W. E. Thorneycroft. (6) "On the Nature of High-Speed Steel," by M. A. Grossman and E. C. Bain. (7) "Improvements in the Brinell Test on Hardened Steel, including a New Method for Producing Hard Steel Balls," by A. Hultgren. (8) "Present Position of the Theories of the Hardening of Steel," by W. Rosenhain. (9) "Effect of Free Surfaces on the Plastic Deformation of Certain Metals," by F. C. Thompson and W. E. W. Millington.

Sept. 8 to 11. Institute of Metals, Annual Autumn Meeting, to be opened at the Institution of Mechanical Engineers, when W. M. Corse, S.B., will deliver the third annual Autumn Lecture. On September 9 the morning will be devoted to reading and discussion of papers, followed by luncheon at the Connaught Rooms, Kingsway, the afternoon to be spent at the British Empire Exhibition. On September 10 further papers will be presented for discussion, the afternoon being devoted to visits to works. A reception will be held in the evening at the National Physical Laboratory, Teddington.

The following papers will be read.—"A Method for Measuring Internal Stress in Brass Tubes," by R. J. Anderson and E. G. Fahlman. "The Application of the Ideal Solubility Curve to the Interpretation of Equilibrium Diagrams in Metal Systems," by D. H. Andrews and Prof. J. Johnston; "Seventh Report of the Corrosion Research Committee of the Institute of Metals," by G. D. Bengough and R. May; "Comparative Results on Copper-Silicon-Aluminium and Other Aluminium Alloys as Obtained on Separately Cast Specimens and Specimens cut from a Crankcase Casting," by E. H. Dix and A. J. Lyon; "The Determination of Sodium in Aluminium," by D. M. Fairlie and G. B. Brook; "The Extrusion of Brass Rod by the Inverted Process," by R. Genders; "Investigation of the Effects of Impurities on Copper. Part II—The Effect of Iron on Copper," by D. Hanson and Grace W. Ford; "The Relationship Between Tensile Strength, Temperature and Cold-Work in Some Pure Metals and Single Solid Solutions," by D. H. Ingall; "On the Effect of Progressive Cold-Rolling on the Brinell Hardness of Copper," by H. Moore; "Experiments on the Working of Nickel for Coinage," by Sir T. K. Rose and J. H. Watson, "Some Experiments on the Effect of Casting Temperature and Heat-Treatment on the Physical Properties of a High-Tin Bronze," by F. W. Rowe, "Some Experiments on the Influence of Casting Temperature and Mass on the Physical Properties of Admiralty Gun-Metal," by F. W. Rowe; "Studies in the Aluminium-Zinc System," by T. Tanabe; "Metal Spraying and Sprayed Metal," by T. H. Turner and W. E. Ballard.

SOCIÉTÉ DE CHIMIE INDUSTRIELLE

On June 27, the Fuel Group listened to a paper by Prof. M. P. LeBeau on the "Thermal Fractionation of Gases Resulting from the Carbonisation of Solid Fuels."

The method which is utilised by the author consists in heating 1 g. of fuel in a vacuum at temperatures increasing by 100° C. every hour, up to 1000°, and extracting the gases given off at each interval of temperature, liquid and less volatile products being retained in a condenser cooled to 80° by a mixture of acetone and carbon-dioxide snow. The measure of the volumes of gas and the analysis of the various fractions give data from which a curve representing the thermal fraction for each fuel can be established. The method has been applied to the study of anthracite, coal, lignite, peat, pine and oak wood, and the curves obtained were found to be characteristic of the products examined, each fuel and group of fuels having a special type of curve which was always the same for any single fuel. Further developments show that the method can also be applied to the characterisation of groups of carbohydrates such as glucose, galactose and starch. On carbonising nitrogenous compounds such as casein and egg albumin very different curves were obtained. The interest of the method lies in the fact that it furnishes valuable indications for the utilisation of fuels, that it makes a new classification possible, and may even provide useful help in the elucidation of their chemical constitution.

FARADAY SOCIETY

At the Annual General Meeting held on July 7, Professor F. G. Donnan, C.B.E., F.R.S., was elected to succeed Sir Robert Robertson as President. The Annual Report records considerable activity during the past year, the result of which is reflected in the accounts, which show a deficit of £109 11s. 5d. on the year.

Eleven meetings in all were held during the year and of these four were General Discussions, which have become so striking a feature of the work of the Society. The subjects of these were as follows: I. Alloys Resistant to Corrosion. II. The Physical Chemistry of the Photographic Process. III. The Electronic Theory of Valency. IV. Electrode Reactions and Equilibria. The widespread appreciation in which the publications of the Society are held is indicated in the fact that the sales of Transactions and reprints amounted to nearly £900, a figure in excess of the amount received for subscriptions.

It is very surprising to note that the membership of this very active Society is only 432 and that consequently an appeal for a larger membership is made in the Annual Report. Particulars relating to the Society may be obtained from the Secretary and Editor, Mr. F. S. Spiers, 90 Great Russell Street, London, W.C. 1.

ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS

ANNUAL GENERAL MEETING

The Eighth Annual General Meeting of the Association was held at the Chemical Society's Rooms, Burlington House, Piccadilly, W. 1, on Thursday, July 17, 1924. Sir Max Muspratt, Bart., occupied the Chair. The Chairman, in moving the adoption of the Annual Report, said: The Association has again gone through a most successful and important year. We have no changes in the personnel of the Council to record, but there are members of Council who have taken up work in other spheres where their co-operation is very valuable. Our General Manager, not being satisfied with the small scope which the Association affords him, has become the President of the Society of Chemical Industry. Much as the members of the Council felt that it was asking them a great deal to allow their General Manager to devote much of his time to the other important body, we felt that in the interests of co-operation between everyone concerned with chemical industry and chemical science, we ought to grant the permission, and I feel confident that all the members agree with that wise course. (Applause.) Undoubtedly in the past the Society of Chemical Industry and the Association of British Chemical Manufacturers, although their membership in many ways overlapped, were not working in the close co-operation that was best for the members of the two bodies, and I am extremely pleased to think that under the late President of the Society of Chemical Industry, Dr. Armstrong, and under the presidency of our General Manager, Mr. Woolcock, that co-operation and close working together is going to be enormously improved. I have just come from Liverpool, where the Annual Meeting of the Society of Chemical Industry was held last week, and I believe it was a most successful gathering. The thing that I gathered from it was that the close co-operation between manufacturers and others associated with the chemical industry has made great strides in the recent past, and, I venture to think, with satisfaction and advantage to both bodies it will continue to make even greater strides in the future.

Another method of co-operation between those interested in chemistry has been afforded by the very prominent part that this Association has taken in the British Empire Exhibition. When other industries were standing back and could not make up their minds, the Chemical Industry did decide that they were going cordially to support the Exhibition and the result, I venture to think, is an exhibit second to none of any given in the world, showing the complete range from the simplest domestic chemical products, through the more refined products, right away up to the pure Scientific section. It is a chemical education for all who go to the Exhibition. Nothing of the kind has been tried before, and no great exhibition in the future, I venture to say, will be complete which does not carry on that idea. The Exhibition not only brings

chemical manufacturers and consulting and scientific chemists and others interested together, but it is giving a great message to the whole world. It is showing the position this country occupies in science and chemical industry and a vast number of students from all parts of the country are flocking to that Exhibition and spending much of their time in the chemical section Those students will help to form an enlightened public opinion of the next generation. and it is most valuable that chemical industry should thus take its right position. But the response of the general public also has been enormous. Even on a day like Bank Holiday when one would think that the "Fun Fair" would attract all those who were in the Exhibition grounds, the numbers who visited the chemical portion were very large, and very many bought those sixpenny text books which were sold in the scientific section, showing how seriously and earnestly the general public are now taking the chemical industry. Then again the influence upon the world at large, the distinguished men and women who are coming from all parts of the world, the visits of scientists, industrialists, politicians, statesmen and others, means that a large proportion of these are being influenced by what they are seeing at that Exhibition in which our Section, we venture to say, is one of the most excellent. It has been mooted in high quarters that it may be possible that the Exhibition will be opened again next year and succeeding years. I for one cordially welcome the suggestion and I hope that the chemical industry will again, as it has done this year, support it. I am certain that direct and indirect advantages to the whole industry and the individuals composing it will accrue.

There is a reference in the Report to the films for chemical industry. These films are being shown in quite a number of cinematograph halls throughout the country and they help to concentrate interest in the chemical industry. Any firm who wishes to give a private exhibition for their working people or people who might be interested in their particular line of business can always obtain the free use of these films just for the cost of the carriage.

On the subject of dyestuffs so much has been said and thought that I do not propose to make any long statement. All I wish to point out is this, that the subject is extremely difficult, and within the Association the interests are very conflicting. The Council of the Association has tried to keep the balance between these various interests and to make representations in the right quarter, not with a view to what is good for this firm or that firm, or for any group of firms, but to what is best for the whole industry. If at times we have trodden upon the corns of specific interests, that has got to be done if we are to do our duty by the whole of the members of the Association.

There is just a reference in the Report to the Safeguarding of Industries Act. Unfortunately that has come into a sphere where political ideas play a larger part than industry; but Part I is still to continue in operation for some little time to come, and I hope that as far as possible the subject will be kept away from political principle or prejudice —words, I am afraid, at times synonymous.

A question that is coming forward in the near future is the Consolidated Factories Bill. This deserves serious consideration. The Association has not taken a narrow-minded view with regard to such legislation; it has always tried to see the principles which the Board of Trade or the Home Office wished to have enforced in industry. At the same time it has taken the necessary steps to watch the matter, not with a view to blocking the progress of the principle but to see that something workable comes out as a result of the discussions which have taken place. We are taking the same course of action in this field as we have taken in others—that is to say, we are approaching the matter with a sympathetic mind, with a desire to live in the present day, not looking upon the practice of the past as anything sacred which must not be touched; we do want to have good conditions for our work-people. We want them to live their happiest lives through their time in the factory, but at the same time we venture to think that we know the psychology of our workers a good deal better than any Government officials can do, and we think that some kind of latitude and elasticity should be given in these regulations. There is no object in putting in wash-bowls, for example, when we know perfectly well that they are put in in places where they will never be used. We want to make employment easier and pleasanter in our works, but we do not want to be run into a great deal of unnecessary expenditure which is not going to have any result in the way of happiness for our workpeople.

In the question of Patent Law, Chemical Industry is largely interested, and seeing that a Trade Marks, Patents and Designs Federation has been formed, the Council has appointed a very excellent representative in the person of Dr. Ree. Next comes the question of assessment for rating.

The rating laws of this country are an absolute quagmire. The thing has grown up with no definite principle as to how rates should be levied, and in this attempt under the Rating of Machinery Bill to deal with one section of the problem almost every other section has been involved, and every kind of principle (or want of principle) in connection with rating has had to be considered and if possible consulted. Personally I am not very hopeful that very much is coming out of this Rating of Machinery Bill, and we can only hope that the enquiries that are going forward with regard to the whole principle of rating will, in the course of two or three years, cause something to emerge that will put upon Chemical Industry- the members of which, let it be remembered, are citizens—a fair incidence and not an unfair incidence. We do not want to push our burdens upon other people, but, on the other hand, we do not want to carry unfair burdens, and I hope that every member who can suggest how such consolidation can be obtained will give us the benefit of his experience.

The Census of Production is shortly to be renewed. I welcome that decision very much indeed. The difficulties in quite a number of chemical industrial

problems are due to the fact that nobody knows the condition in which industry stands in this country, and one has to accept any statements that suit the particular point of view that a speaker is elaborating. A Census of Production, properly carried out, in the course of a decade at the outside, will give a mass of definite information which will enormously aid us in all these problems, of unemployment, of health, of taxation and of rating, and I am delighted to think that upon the Committee which is to decide the form that this Census is to take Mr. Perry has been nominated. It is a great responsibility, but we could not have it in more efficient hands.

Referring to the fact that he was addressing them for the last time as Chairman of Council, Sir Max Muspratt thanked the members of the Council and the staff for the loyalty, the hard work, the initiative and the common sense which they had shown, and which had made it a very easy and delightful duty to be Chairman of the Council.

The Treasurer (Mr. C. A. Hill), in seconding the Report, dealt more particularly with the balance-sheet of the Association.

In the course of the general discussion Dr. E. F. Armstrong referred to the question of transport. There were, he said, a very large number of bodies interested in the question of transport charges. All present, both in their capacities as industrialists and as private individuals, knew that the amalgamation of the railways had so far been of doubtful benefit to the public, and he felt that it was most important that an Association like their own should be very watchful of their interests on this point. If the railways took them in detail they were lost, but they might achieve something by standing together. He thought they could not congratulate themselves too much on their success at Wembley. The idea of having an exhibit at Wembley was undoubtedly their own, and although perhaps the idea of the Scientific Section did not originate in their Council, he asserted that nobody else would have carried it out in the way it has been carried out except the Association.

Dr. Levinstein said he would like to emphasize the great value of the co-operation with the scientific societies which had been made. The success of the scientific exhibit was very largely due to the assistance given by the Royal Society. They had found a most willing and friendly spirit, and were able to mark out a sphere of influence for the Association. As one who knew a great deal about the subject of dyestuffs he was naturally precluded from making any useful remarks! (Laughter.) He contented himself with endorsing the very diplomatic language of the Report. He thought the Association was going on from strength to strength, and that the Report spoke very favourably for the position of the Chemical Industry in this country.

Sir John Brunner, Bart., referred to the Chemical Engineering Department of University College, London. The Association knew that an experiment was being tried in education—namely, to form what was very sorely needed in chemical work, a means of study for the chemical engineer. It had been a great point of controversy among those who manage chemical works whether it was possible, in the time which is allotted to a student, to make a chemical engineer. Many people thought that if you were to try to perform any such task you would turn out a half-baked engineer and a half-baked chemist, and that it would be very much better to divide your own staff into two, to have a thoroughly well-trained chemist and a thoroughly well-trained engineer. But there were very many places in our far-flung Empire where one could not afford to have a large staff, and it seemed to him that there would be great openings for the men trained in this Chemical Engineering Department. Every man so trained would be able to go abroad and take jobs single-handed as managers of, not exactly chemical works, but works where chemistry is a very essential part in the running of the works—such as a sugar factory.

The Rt. Hon. J. W. Wilson referred to the questions in the Council which require very delicate handling. He believed that the Council in the past year had always endeavoured to work for the general welfare of the Chemical Industry, and he thought that on the whole the results had been satisfactory, and the Association had amply justified itself, even apart from Wembley.

Mr. Sadler suggested that the Association should pay its way, and that they should call up the full 100 per cent. for this next year.

Dr. Ree (Chairman of the Manchester Chamber of Commerce) said that the Association had fulfilled to a great extent the ideals with which it started. In the old days there was a good deal more friendliness between the British and German manufacturers than between the British manufacturers themselves. That condition of things was now completely altered, and very much to the advantage of the industry.

The motion to adopt the Report was then carried unanimously. The auditors, Messrs. Feasey and Company, were re-elected. Mr. Perry seconded, and this was agreed to.

Mr. Parnaby (Chairman of the Committee of Scrutineers) read the results of their scrutiny, and the Chairman declared the elections duly carried out.

Dr. E. F. Armstrong proposed a very hearty vote of thanks to the Chairman, Sir Max Muspratt, which was seconded by Sir John Brunner, and carried with acclamation.

Annual Dinner

In the evening the Annual Dinner of the Association was held at Lucullus Restaurant, British Empire Exhibition, Wembley, and was presided over by Mr. D. Milne Watson, D.L., M.A., LL.B., the newly-elected Chairman of the Association. The guests, among whom were a number of representatives of the most important chemical organisations abroad, included the following: Percy Ashley, Assistant Secretary of the Board of Trade, Prof. H. E. Armstrong, Prof. Wilder Bancroft, of America, Vice-President of International Union of Pure and Applied Chemistry, Percy Cazalet, of the Chemical, Metallurgical and Mining Society of South Africa, Prince

Ginori Conti, of Italy, President of the Federazione della Associazione Industriali Chimiche, L. J. Hunt, Prime Warden of the Dyers' Company, Prof. Jedlicka, Chemical Society of Czechoslovakia, Prof. Naoto Kameyama, Society of Chemical Industry of Japan, Prof. Riko Majima, Chemical Society of Japan, S. J. Pentecost, President of the Society of Dyers and Colourists, Dr. Sieger, of the Dutch Chemical Society, Dr. Werner Stauffacher, of the Swiss Dyestuff Industry, N. Garrod Thomas, Prof. J. F. Thorpe, of the Imperial College of Science, Dr. Valeur, of the Societe Chimique, and Prof. A. von Weinberg, Vice-President of the German Chemical Society.

After the company had drunk the toasts of His Majesty the King, and of the Rulers of the Countries represented by the guests, the Chairman proposed the toast of the evening, "Our Guests," coupled with the names of Prof. Wilder Bancroft, of America, Prince, Conti, of Italy, Dr. Valeur, of France, and Prof. von Weinberg, of Germany; to which the four gentlemen suitably responded

The evening concluded by a visit of the members and their guests to the Chemical Section of the Palace of Industry.

CORRESPONDENCE

INTERNATIONAL AMITY

Sir,—Your issue of May 2 has just come to hand, and I note that you are again referring to the question of international amity which has been raised by yourself first in the issue of February 29 and the discussion of which has been joined by Dr. Fritzsche and Prof. Noyes. Perhaps by the time this letter reaches you the whole subject will be dropped, still in spite of this I cannot resist the impulse to write down what I think about it.

All through this discussion you have referred to scientific men in general, and to chemists in particular, as if they were apart from the general community in their feelings and emotions with regard to such complicated and difficult matters as are involved in the making of peace and war. Now I venture to suggest that this view is unsound: in our consideration of matters like this we should *first* regard ourselves as ordinary men and women, full of human strength and weakness, loves and hates, joys and sorrows, and all those unmeasurable qualities which make men and women what we know them to be, and afterwards if it so happen that our scientific training should enable us to see through these complicated problems a little more clearly than our fellows, then and then only should we use our knowledge, not indeed as scientific men, attempting the solution of a definite scientific problem, but just as ordinary human individuals, seeing things a little more clearly, if you will, but from the same standpoint as that of ordinary people.

I cannot help feeling that Professor Noyes has completely overlooked this aspect of the matter when he wrote his notes of to-day's issue (May 2). The last paragraph of his letter suggests the following:—Let all this struggling, starving, passionate, disappointed mass of people which fills Europe to-day be changed—so that all their evil passions and ambitions shall pass away and they shall become as angels, singing glory to the League of Nations and the World Court for evermore.

If Prof. Noyes will attain his ambition to lead rather than follow the financiers and politicians, he will first have to produce a policy which will be able to resist the subtle attack of these, the most cunning and most learned of all men in human iniquity; and not one which carelessly disregards all those simple emotions which may be connoted by the words "human nature"! I think it was you, Mr Editor, who a short time ago was urging chemists occasionally to forget their theories and be plain men, and I for one feel sure that the theories would not suffer much thereby.

As for Dr. Fritzsche's attitude as expressed in his two letters, there is little difficulty in understanding what he means, taken all round he persists that Germany did what she held to be right and proper, and he as a German is not going to say, or—let any one else say—anything else. His one weakness appears to be that he is not prepared to concede this position to any other person in respect to their own views and conduct. The former aspect of the matter is logical and comprehensible, the latter is equally incomprehensible.

As far as making friends with the Germans goes it seems to me a matter of the greatest difficulty, I have tried it personally with one or two individuals but they all seem to follow the method of Dr. Fritzsche, and that appears to lead nowhere; while taken as a whole it would appear that the Germans made peace at a moment which, from a military point of view, was most fortunate for them, and, having stopped the war, they made a treaty which they have quite frankly done all in their power to avoid keeping. This appears to be the general situation viewed from a distance. No doubt much argument might be made on both sides, but I submit that the ordinary commonsense person in whom taken in the aggregate the general power of the nation at present lies, sees the matter in this light, and that being so Prof. Noyes' proposition seems more hopeless than ever.—I am, Sir, etc.,

Botany, N.S.W. HARRY WILLIAMS

P.S.—I have not read Prof. Noyes' pamphlet, but I feel sure that the general tenor of his theme may be comprehended for its colour in the issue of May 2.

INDUCED ALTERNATE POLARITIES

Sir,—In your issue of July 25, Prof. Ingold records his opinion against the theory of induced alternate polarities as being a false combination of correct ideas. Whether or not the theory offers a true explanation of facts, it is evident that the *polar* and *alternate* influences in a carbon chain are very intimately connected with one another.

In a recent paper (*J.C.S.*, 1924, **125**, 1121) attention has been drawn to the influence of substituents on optical activity, particularly of the *d*-amyl complex $C_5H_{11}X$ and the menthyl esters of *o*-substituted benzoic acids. In these and other cases groups

produce characteristic changes in the molecular rotation of a parent compound, and positive and negative groups influence the rotation in opposite directions. There is here, so far as present evidence shows, no trace of an alternate nature, and the influence of the group may be described as polar. Nevertheless, the relative effect of different groups goes hand in hand with the alternate influence of these same groups upon benzene substitution and other properties, and the two sets of phenomena would appear to have a common origin.

With respect to the question raised by Prof. Lapworth in your same issue of a tervalent nitrogen "key atom" acting in opposition to one of biovalent oxygen, it is interesting to note that in the amyl series referred to above the hydroxyl group produces practically the same change in rotation as the amino group, amyl alcohol being quoted as $[M]_D = -5{\cdot}19°$ and the amine as $[M]_D = -5{\cdot}10°$. Possibly, however, the latter figure may yet be revised in an upward direction.—I am, Sir, etc., H. G. RULE

Edinburgh University

REPORTS ON WATER ANALYSES

Sir,—Reports on water analyses are rarely satisfactory in England. Reform is needed principally in three directions.

1. The experimental figures should be given: no attempt should be made to combine basic and acidic radicals.

2. Results should be expressed in parts per hundred thousand only.

3. The phraseology should be that adopted in other branches of chemical work.

Practically all water reports fail to conform to these requirements. The first is the most important. At present, reports issued by water analysts give tables purporting to show in terms of *salts* the probable constituents of the water. That such tables are widely divergent from the facts must be admitted by all chemists who accept the dissociation theory and as all but a few chemists do accept this theory, the sooner these tables are suppressed the better.

Nowadays the analytical data are usually given but unfortunately particulars of salts which have no objective existence are also furnished. The number of chemists who believe that the basic and acidic ions present in a water are totally or even principally in the combined state must be negligibly small and yet reports showing them to be totally in the combined state are still issued.

2. Most reports give the results in parts per 100,000, but they are also unnecessarily given in grains per gallon.

3. Expressions such as "fixed carbonic acid," "combined and semi-combined CO_2" and "hardness" should be eliminated. Some slight advantage might be obtained by retaining the word "hardness," but if retained it should have only one meaning. To some chemists it means "$CaO+MgO$ expressed as $CaCO_3$," but others include sodium chloride. For the use of the remaining terms, however, there is no excuse as ordinary chemical nomenclature is quite as convenient.

There is an urgent need for a modern book on water analysis. Possibly when such a book is available chemists will be persuaded to discard the present unscientific method of reporting on waters.—I am, Sir, etc., G. THOMPSON

5, International Mansions,
High Street, Rugby

PERSONAL AND OTHER ITEMS

Prof. F. G. Donnan, C.B.E., F.R.S., has been elected to succeed Sir Robert Robertson as president of the Faraday Society.

Prof. V. C. Myers, Director of the biochemical department of the New York post-graduate medical school, has accepted the chair of biochemistry in the Iowa State University.

The American Portland Cement Association proposes to erect a bronze tablet in Leeds to the memory of Joseph Aspdin, a bricklayer of Leeds, who in 1824 patented a formula for a material which, when hardened, resembled Portland stone and which ultimately became known as Portland cement. If accepted by Leeds, the tablet will be unveiled on the occasion of the united celebrations with the British Cement Makers' Federation of the centennial of the invention, October, 1924.

Early this year the Imperial College of Science and Technology was enabled, by generous donations from Sir Arthur Acland, Bt., and Sir Otto Beit, Bt., to establish a scheme of 10 Dominion Scholarships for research work in science, tenable at the college during the academic year 1924–25, open to university graduates in the several Dominions and in India. With the co-operation of the India Office and the Colonial Office, appointments to these scholarships have now been made by the respective Governments as follows:—

India.—Mr. Sarbbanisahay Guha Sircar (Calcutta University); Mr. A. S. Ganecan (Madras University). *Australia.*—Miss M. I. Collins, M.Sc. (University of Sydney) (for work in economic botany, including forestry); and Mr. A. S. Fitzpatrick, M.Sc. (University of Melbourne) (for work in applied chemistry, specially in relation to fuels). *Canada.*—Mr. Armand Circe, C.E. (Ecole Polytechnique, Montreal); and Mr. R. J. Henry, B.A., B.Sc. (University of Toronto). *New Zealand.*—Mr. H. L. Richardson, M.Sc. (Victoria University College, University of New Zealand); and Mr. H. O. Askew, M.A. (Canterbury College, University of New Zealand). *South Africa.*—Mr. Hans Pirow (for mining engineering) and Mr. Lawrence P. McGuire (for plant physiology).

The Ramsay Memorial Fellowship Trustees have made the following awards of new Fellowships for the session 1924–25:—

A British Fellowship of £300 to Mr. S. W. Saunders, B.Sc., for work at University College, London. A Glasgow Fellowship of £300 to Mr. Alex. Robertson, M.A., B.Sc., for work in the University of Manchester. A Danish Fellowship of the value of £229 to Mr. Kai Julius Pedersen, for work in the University of Bristol.

The Trustees have renewed the following Ramsay Fellowships for the same session: Dr. Samuel Coffey (British Fellowship), for work at University College, London; Dr. Alan Titley (British Fellowship), for work in the University of Oxford; Mr. Thomas S. Stevens (Glasgow Fellowship), for work in the University of Oxford; Dr. Miguel Crespi (Spanish Fellowship), for work at University College, London; Dr. J. Kalff (Netherlands Fellowship), for work in the University of Manchester. Dr. H. Weiss (French Fellowship), for work in the Davy Faraday Laboratory, Royal Institution; Dr. Edward Boomer (Canadian Fellowship), for work in the University of Cambridge.

Sir Robert Robertson, F.R.S., has been appointed a member of the Ramsay Memorial Advisory Council, in place of the late Sir James Dobbie.

The death has occurred of Miss K. A. Burke, who, after being private assistant to Sir William Ramsay, became the first woman member of the teaching staff of University College, London. Miss Burke was a most capable teacher, and had a great share in the development of the social and athletic life of the college.

New Technical Journal

A new scientific publication to be known as the *Journal of Oil and Fat Industries* will shortly be published by the American Oil Chemists' Society. This periodical will be devoted to the chemistry and chemical engineering of all phases of the manufacture and uses of animal and vegetable fats and oils. The first issue will appear early in July from the Eschenbach Printing Company's press at Easton, Pa., Subscriptions for the Journal may be addressed to H. S. Bailey, Editor, Box 756, Savannah, Ga., or T. B. Caldwell, Secretary of the Society, Law and Co., Wilmington, N.C.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Government Wool-Disinfecting Station

Mr. Davies, replying to Mr. Hannon, said that there was a profit on current expenditure since the beginning of the present financial year in regard to the Government Wool-Disinfecting Station. The total accrued loss on March 31, 1924 (including interest on capital expenditure and an allowance for depreciation) was approximately £54,000.

The New Geological Museum

Replying to Major Church, Mr. Jowett said it had been decided to erect a new building in South Kensington to house the Geological Survey and the Museum of Practical Geology, and a supplementary estimate to provide the necessary funds would be presented at an early date. The future of the present site of the Museum was not yet decided, but the administrative work was being carried on there, and the public would have access to the library and map room.—(July 28.)

REVIEWS

Text-Book of Cellulose Chemistry. By Emile Heuser. Translated from the Second German Edition by Clarence J. West and Gustavus J. Esselen, Jr. Pp. xi+212. London. McGraw-Hill Publishing Co., Ltd., 1924. Price 12s. 6d.

The task of compiling on systematic scientific lines a record of the chemistry of cellulose is beset with many difficulties. The unwieldy literature of the subject is scattered and its study is complicated by the fact that, in many cases, the investigations described have a technical objective or are conducted in a spirit of light-hearted speculation which is repellant to the scientific thinker. A text-book of cellulose chemistry has further to satisfy many different types of readers and, if the subject is dealt with on the basis of molecular structure, the arguments have, in the end, to meet the criticism of the specialist in the complicated subject of sugar chemistry.

It is therefore with a feeling of sympathy for Professor Heuser and with a full appreciation of the difficulties which have been faced, and for the most part overcome, that the reviewer has studied the present English translation. The aims of the book and the spirit in which it should be read are clearly defined in the Introduction. Adopting throughout the method of illustrating each type of reaction by reference to the behaviour of simple aliphatic hydroxy-compounds, the author deals in succession with cellulose acetates, esters and ethers, proceeding thereafter to the oxidation and degradation of the polysaccharide. This leads naturally to a closing chapter dealing with the molecular structure of the cellulose unit.

Generally speaking, the book is likely to fulfil the aim of the author, and readers, whether their interests lie in the laboratory or the factory, will profit by having their attention focused on the reactions of cellulose which can be interpreted in terms of constitution. The book suffers, however, from the defect (one to which we have been long accustomed) that it creates the impression that cellulose chemistry rests essentially on the work of Continental, and more particularly, German investigators. There is also a tendency to make sweeping generalisations with a confidence which is not justified. For example, the statement that there is only one type of cellulose, which is the same chemical individual in all plants, may well be challenged and the assurance that starch, inulin, glycogen, cellulose and the pentosans all "consist of a polymeric form of a hiose anhydride of similar chemical composition" is entirely misleading. Sins of omission, partial and complete, are also common. Barnet's method of acetylation is not mentioned and the acetylation of cellulose is in consequence discussed at considerable length as an example of acetolysis. Another case calls for stronger criticism. Description of the methylation of cellulose is confined to an extract from the introductory paper by Denham and Woodhouse published many years ago. Although

later references are quoted in a foot-note, the author's account of the application of methylated celluloses to constitutional questions is based merely on preliminary experiments and reveals incidentally an imperfect acquaintance with the properties of methylated sugars. The tendency of the author to limit his readers to the work of German investigators reaches a climax in the constitutional discussion in Chapter VI where he is courteously corrected by his translators who have inserted a synopsis of British and American researches which cancels out practically the whole of the chapter in question

Professor Heuser's book has deservedly reached a second edition, and further issues will doubtless be forthcoming. An excellent start has been made in rendering the literature of cellulose accessible in a form in which it can be studied intelligently, but the author will probably be the first to admit that it is no more than a start and that there is room for many improvements. The translators have carried out their task accurately and, although adhering closely to the original, have not hesitated to insert notes where corrections were necessary.

J. C. IRVINE

WOODFIBRES OF SOME AUSTRALIAN TIMBERS. By R. T. BAKER and H. G. SMITH. Pp. 159, 64 plates. Sydney: Government Printer, 1924. Published by the Authority of the Commonwealth Government.

During the war a shortage of paper was experienced in Australia, and in 1916 a committee was appointed by the Government of New South Wales to enquire into the prospects of making paper locally from indigenous timbers. In the publication under notice Messrs. Baker and Smith record the results of investigations begun during their membership of this committee and continued for some time subsequently. The fibres of about sixty " forest " and " brush " timbers of Eastern Australia have been characterised and illustrated, and the yield of cellulose determined for each wood. Eucalyptus timbers naturally figure largely in the work, and the results obtained for the " Ash " group of this genus, taken in conjunction with a survey of other manufacturing requisites, lead to the conclusion that a paper mill producing 13,500 tons of pulp per annum, equivalent to one-fifth of the annual Australian pre-war consumption of newspaper, might well be erected and maintained in full employment in the Buddong Falls district of New South Wales. In an assessment of 28,000 acres of Crown lands available in this district it is estimated that out of 32 trees per acre useless for lumbering purposes the greater portion (including 16 of *E. Dalrympleana* and 12 of *E. Delegatensis*) could be used for pulp production. An ample supply of water of the requisite purity is available in the area concerned.

The pulp from *E. Dalrympleana* is stated to resemble chestnut wood pulp; and the eucalyptus wood when cooked for four hours by the sulphate process gave a 47·8 per cent yield of a very satisfactory grade of pulp, which could be easily bleached. "The accumulated evidence shows that certain eucalyptus species having light coloured timber, and growing in considerable quantity on the eastern portion of Australia, in close proximity to abundant water supplies, are well suited for the production of chemical pulp for the manufacture of paper " Furthermore, the ascertained rate of reproduction of these species upon reafforestation is one of the most rapid known.

Eucalyptus wood fibres do not usually much exceed one millimetre in length, but long-fibred pulp has been produced commercially from the Queensland Pine (*Araucaria Cunninghamii*), the tracheids of which reach as much as 9 millimetres in length, although they mostly range between 3 and 4 millimetres. In addition, the authors indicate that several of the ' scrub ' timbers growing at the head of the Clarence River show considerable promise as sources of long-fibred pulp Among a group of 13 of the best species are *Grevillea robusta* (silky oak), *Doryphora sassafras* (sassafras), *Ceratopetalum apetalum* (coachwood), and *Eugenia* sp. (water gum).

In spite of the valuable work here recorded, and the patiently compiled reports of more than one committee, little or no effort has yet been made to develop on a commercial scale the latent natural resources of Australia which are dealt with in this investigation. By this publication, however, Messrs. Baker and Smith have added a further noteworthy contribution to their lengthy series of botanical and chemical investigations on the unique and wonderful flora of Australia, and have indicated once again an important line of prospective economic development.

JOHN READ

PRINCIPLES OF ELECTROPLATING AND ELECTROFORMING (ELECTROTYPING). By W. BLUM and G. B. HOGABOOM. Pp. xii+356. London McGraw-Hill Publishing Co , Ltd , 1924. Price 20s.

This volume appears to have been directly inspired by the activities of the American Electro-Platers Society, a society which has shown great activity and undoubtedly accomplished valuable work in the United States of America in raising, not only the status of the electro-plater himself, but the standard of his work. The book is, therefore, of considerable interest, since for this reason it may be taken as embodying the best of American practice in the art of the present day.

A very wide field is covered in the twenty-one chapters of which the book consists. The principles of chemistry, electro-chemistry and chemical analysis are dealt with, not anything like adequately, but sufficiently so perhaps to meet the needs of the great majority of interested readers.

Some of the definitions given are not sufficiently clear for modern standards of accuracy, and indeed are not always correct as, for example, the definition of an electrolyte as " the solution through which the current passes " (see page 53) The book suffers to some extent, also, from the attempt to crowd too much matter in comparatively limited space, and there is a want of balance, some matters of minor

importance being stressed in undue proportion. On the whole, however, the book will be a most useful handbook for English workers in the art, and especially for those workers who are interested in improving methods of practice.

It has been hitherto somewhat difficult to obtain in convenient form details of American practice, and much of the information conveyed in this book, though not known to students of American technical literature, has not been available to the average electro-plater in this country. The authors are to be congratulated on a publication which can be recommended to practical workers as a thoroughly useful and, on the whole, reliable handbook.

W. R. Barclay

Physikalische Chemie. By Alfred Benrath. Pp. viii+107. Dresden and Leipzig: Theodor Steinkopf. Price, paper, 2s.

This little volume constitutes the eighth part of a work on physical chemistry, which is being prepared under the general editorship of Prof. R. E. Liesegang, with the object of giving a summarised account of the work on physical chemistry published during the years 1914–1922. The editor hopes in this way to supply a book which will enable those who lost touch with the literature of these years, to obtain an acquaintance with it without the expenditure of a large amount of time and energy.

In the present volume the author deals with the physico-chemical properties of pure substances and solutions. The treatment of pure substances occupies only 22 pages and deals mainly with the relationships between the physical properties of elements and compounds, and the theory of allotropy. Smits' theory of allotropy and Cohen's work on the same subject are reviewed. The passivity of iron is considered in connexion with Smit's theory of allotropy.

The remainder of the book is devoted to the work on solutions. These are considered under the headings (*i*) Solutions of indifferent substances and (*ii*) solutions of electrolytes. Under the last-named heading the author considers the newer developments of the theory of electrolytic dissociation, the theory of complete dissociation, the theory of indicators and the dissociation of molten and crystallised salts. The newer theories of solvate formation are also considered.

The author has done his work faithfully and in many cases he has considered the various subjects from a date much earlier than 1914, but he has not treated the material in the strictly critical manner which might well have been expected in a work of this nature. The book will, without doubt, be extremely useful to those wishing to become acquainted with the recent developments in the subjects treated, and to such it may be recommended. But for those engaged in work on these subjects the book offers little or nothing with which they are unacquainted, and it is to these that the absence of a strictly critical treatment robs the work of the real value and usefulness which it might so easily have possessed.

J. F. Spencer

Elements of Water Bacteriology, with Special Reference to Sanitary Water Analysis. By Prof. S. C. Prescott and Prof. C. E. A. Winslow. Fourth Edition, Rewritten. Pp. viii+211. New York: John Wiley and Sons, Inc.; London: Chapman and Hall, 1924. Price 11s. 6d.

The fourth edition of this useful handbook has been brought up-to-date and partly rewritten. The printed page has been enlarged and the size of type changed. It gives a concise review of the present methods adopted in the bacteriological examination of water and water supplies from the sanitary point of view. The aim of the book is to give an adequate idea of current American practice, and the authors have accepted the proceedings outlined in the last report of the Committee on Standard Methods of the American Public Health Association They have succeeded in presenting a critical discussion of the wider principles involved, which are essential to the water bacteriologist, and to the student who desires to acquire a fundamental comprehension of the problems with which he will have to deal in actual practice.

British methods of investigation and interpretation are closely in accord with those used in America, and the general trend of work in both countries is to focus attention on procedures which are rapid and which have proved themselves of definite value.

As *B. Coli* has been accepted as the best index of pollution and of especial value in the control of filtration plants, the authors have deleted much of the less important details in historical development given in the last edition.

The report of the English Committee appointed to consider the standardisation of methods for the Bacteriological Examination of Water of 1904, is referred to, but British readers should be reminded that a second Committee reported in 1914 (*Journal of State Medicine*, Vol. 22, p. 558).

The number of water laboratories in the United States has increased largely since 1910, and the authors have thought it wise to reduce the amount of space devoted to the isolation of the typhoid bacillus, since this step is so rarely undertaken by water bacteriologists.

One short chapter is devoted to the bacteriology of sewage and sewage effluents, and another to the bacteriological examination of shell-fish.

The valuable bibliographical list of 365 references to books and papers of the third edition has been retained, and in the present edition a further 141 have been added.

The authors have a world-wide reputation and this book should prove of great value and will doubtless be cordially welcomed by students and all those engaged in the control of water supplies, whether they be laboratory investigators, engineers or medical officers of health.

John I. Goodlet

Prof. J. B. Baillie, professor of moral philosophy in the University of Aberdeen, has been appointed Vice-Chancellor of the University of Leeds.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.
Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech. .. £23 10s. per ton.
Acid, Boric, Commercial—
  Cryst. .. .. .. £45 per ton.
  Powder .. .. £47 per ton.
Acid Hydrochloric .. 3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw. .. £21 10s.—£27 per ton makers' works according to district and quality.
Acid Sulphuric .. .. Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali.. .. £6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder .. Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime .. £7 per ton, packages extra.
Borax, Commercial—
  Crystal .. .. .. £25 per ton.
  Powder .. .. £26 per ton.
  (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride .. £5 17s. 6d. per ton d/d.
Mothylated Spirit 64 o.p.—
  Industrial .. .. 3s. 1d.—3s. 5d. per gallon, according to quantity.
  Mineralised .. .. 4s. 2d.—4s. 6d.
Potash Caustic .. .. £30—£33 per ton.
Potass. Bichromate .. 5¾d. per lb.
Potass. Chlorate.. .. 3d.—4d. per lb.
Salammoniac .. .. £32 per ton d/d.
Salt Cake.. .. .. £3 10s. per ton d/d.
Soda Caustic, solid .. Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals .. .. £5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98% .. £24 per ton.
Sod. Bicarbonate .. £10 10s. per ton, carr. paid.
Sod. Bichromate.. .. 4½d. per lb.
Sod. Bisulphite Powder 60/62%.. .. .. £18—£19 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate .. .. 3d. per lb.
Sod. Nitrate refd. 96% .. £13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Sulphide conc. 60/65 About £14 10s. per ton d/d.
Sod. Sulphide cryst. .. £9 per ton d/d.
Sod. Sulphite, Pea Cryst. £15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—
  Golden .. .. .. 5¾d.—1s. 4d. per lb., according to quality.
  Crimson .. .. 1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow 1s. 1d. per lb.
Barytes .. .. .. £3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide .. 3s. 9d. per lb.
Carbon Bisulphide .. £24—£26 per ton according to quantity.
Carbon Black .. .. 7d. per lb. ex wharf. Dearer.
Carbon Tetrachloride .. £56 per ton, drums free.
Chromium Oxide, green.. 1s. 3d. per lb.
Indiarubber Substitutes, White and Dark — 4¾d.—6½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black .. .. 45s per cwt., barrels free.
Lead Hyposulphite .. 7½d. per lb.
Lithopone, 30% .. .. £22 10s. per ton.
Mineral Rubber "Rubpron" .. .. .. £15 10s. per ton f.o.r. London.
Sulphur .. .. .. £10—£12 per ton, according to quality.
Sulphur Chloride .. 3d. per lb., carboys extra.
Thiocarbanilide .. .. 2s. 6d. per lb.
Vermilion, pale or deep .. 4s. 10d. per lb
Zinc Sulphide .. .. 7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—
  Brown .. .. .. £14 10s. per ton d/d. Demand active.
  Grey .. .. .. £19—£20 per ton. Fair demand.
  Liquor .. .. .. 9d. per gall. 32° Tw.
Charcoal .. .. .. £7 5s.—£9 per ton, according to grade and locality. Demand below normal.
Iron Liquor .. .. 1s. 7d. per gall. 32° Tw.
  1s. 2d. ,, ,, 24° Tw.
Red Liquor .. .. 10d.—1s. per gall. 14/15° Tw.
Wood Creosote .. .. 2s. 7d. per gall. Unrefined.
Wood Naphtha—
  Miscible .. .. 5s. per gall. 60% O.P. Market dull.
  Solvent .. .. 5s. 6d. per gall. 40% O.P. Fairly good demand.
Wood Tar .. .. £5 per ton.
Brown Sugar of Lead .. £46 per ton.

TAR PRODUCTS

Acid Carbolic—
  Crystals .. .. 6½d. 6¾d. per lb Quiet.
  Crude 60's .. .. 1s. 9d.—1s. 11d. per gall., according to district. Still quiet.
Acid Cresylic, 97/99 .. 2s 1d.—2s. 2d per gall. Demand still good. Market firm.
  Pale 95% .. .. 1s. 10d.—1s. 11d. per gall. Steady demand.
  Dark .. .. .. 1s. 10d.—1s. 11d. per gall. Steady business.
Anthracene Paste 40% .. 4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—
  Strained .. .. 8½d.—9½d. per gall. Quiet.
  Unstrained .. .. 7½d.—8½d. per gall.
Benzole—
  Crude 65's .. .. 10½d.—1s. per gall. ex works in tank wagons.
  Standard Motor .. 1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
  Pure .. .. .. 1s 8½d.—1s. 10d. per gall. ex works in tank wagons.
Toluole—90% .. .. 1s. 5½d. per gall.
  Pure .. .. 1s. 8d.—2s. per gall.
Xylol coml. .. .. 2s. 3d. per gall.
  Pure .. .. 3s. 3d. per gall.

Creosote—
Cresylic 20/24% .. 9d.—9½d. per gall. Few inquiries.
Middle Oil .. } 5½d.—6d. per gall in Lancashire
Heavy Oil .. } 6d.—7d. per gall. in Yorkshire.
Standard Specification }

Naphtha—
Solvent 90/160 .. 1s. 1d.—1s. 4d. per gall. according to district. Quiet.
Solvent 90/190 .. 1s. 1d.—1s. 4d. Quiet.

Naphthalene Crude—
Drained Creosote Salts £4—£6 10s. Quiet.
Whizzed or hot pressed £9 per ton. Little business.

Naphthalene—
Crystals and Flaked .. £13—£16 per ton in Yorkshire and London respectively. More inquiries.

Pitch, medium soft .. 55s.—60s. per ton f.a.s. for next season. Frequent inquiries.

Pyridine 90/160 .. 19s. per gall. Market less firm.
Heavy .. 12s.—12s. 6d. Little business.

INTERMEDIATES AND DYES

There has been a fair demand for dyestuffs during the past week. Prices remain constant. A number of intermediate products have been reduced in price.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% .. 1s. 7d. per lb.
Acid H .. .. .. 4s. per lb 100% basis d/d.
Acid Naphthionic .. 2s. 4d. per lb. 100% basis d/d.
Acid Neville and Winther 5s. 8d per lb. 100% basis d/d.
Acid Salicylic, tech. .. 1s. 1d. per lb. Improved demand.
Acid Sulphanilic .. 9½d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd. .. .. .. 1s. per lb. d/d.
Aniline Oil .. .. 7¾d.—8½d. per lb. naked at works.
Aniline Salts .. .. 7¾d.—9d. per lb. naked at works.
Antimony Pentachloride 1s. per lb. d/d.
Benzidine Base .. .. 4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95% .. 1s. 1d. per lb.
p-Chlorphenol .. .. 4s. 3d. per lb. d/d.
p-Chloraniline .. .. 3s. per lb. 100% basis.
o-Cresol 19/31° C. .. 4½d. per lb. Demand steady.
m-Cresol 98/100% .. 2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C. .. 2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline .. .. 2s. 3d.—2s. 11d. per lb.
Dichloraniline S. Acid .. 2s. 6d. per lb. 100% basis.
p-Dichlorbenzol .. .. £85 per ton.
Diethylaniline .. .. 4s 7d. per lb. d/d., packages extra, returnable.
Dimethylaniline .. .. 2s. 4d. per lb. d/d. Drums extra.
Dinitrobenzene .. .. 9d. per lb. naked at works.
Dinitrochlorbenzol .. £84 10s. per ton d/d.
Dinitrotoluene—48/50° C. 8d.—9d. per lb. naked at works.
66/68° C. 1s. 2d. per lb. naked at works.
Diphenylamine .. .. 3s. per lb. d/d
Monochlorbenzol .. £63 per ton.
β Naphthol .. .. 1s. 1d. per lb. d/d.
α-Naphthylamine .. 1s. 4½d. per lb. d/d.
β-Naphthylamine .. 4s. per lb. d/d.
m-Nitraniline .. .. 5s. 3d. per lb. d/d.
p-Nitraniline .. .. 2s. 3½d. per lb. d/d.
Nitrobenzene .. .. 5¼d.—5½d. per lb. naked at works
o-Nitrochlorbenzol .. 2s. per lb. 100% basis d/d.
Nitronaphthalene .. 11d. per lb. d/d.
p-Nitrophenol .. .. 1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol 4s. 6d. per lb. 100% basis
m-Phenylene Diamine .. 4s. per lb. d/d.
p-Phenylene Diamine .. 10s. 3d. per lb. 100% basis d/d.
R. Salt .. .. .. 2s. 6d. per lb. 100% basis d/d.
Sodium Naphthionate .. 2s. 3d. per lb. 100% basis d/d.
o-Toluidine .. .. 8½d. per lb.
p-Toluidine .. .. 3s. 6d. per lb. naked at works.
m-Toluylene Diamine .. 4s. 3d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P .. £45 per ton.
Acid, Acetyl Salicylic .. 3s. 2d.—3s. 5d. per lb., according to quantity. Good demand. Price firm.
Acid, Benzoic B.P. .. 3s. 6d. per lb. Larger supplies available.
Acid, Boric B.P. .. Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric .. .. 19s.—21s. per lb.
Acid, Citric .. .. 1s. 6d.—1s. 6½d. per lb., less 5% for ton lots. Business subnormal.
Acid, Gallic .. .. 3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst. .. 7s. per lb. for 1 cwt. lots. Market firm; increasing demand.
Acid, Salicylic .. .. 1s. 6d.—2s. per lb. Weak market.
Acid, Tannic B.P. .. 3s. per lb. Market quiet.
Acid, Tartaric .. .. 1s. 1¼d. per lb. less 5%.
Amidol .. .. .. 9s. per lb. d/d.
Acetanilide .. .. 2s. 1d.—2s. 3d. per lb. for quantity. Demand slow.
Amidopyrin .. .. 13s. 3d. per lb. Neglected. Stocks low.
Ammon. Benzoate .. 3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P. £37 per ton.
Atropine Sulphate .. 12s. 6d. per oz. for English make.
Barbitone .. .. 15s. per lb. Quiet market.
Benzonaphthol .. .. 5s. 3d. per lb. Small inquiry.
Bismuth Salts .. .. A steady market. Prices according to quantity:
Bismuth Carbonate .. 12s. 9d.—14s. 9d. per lb.
" Citrate .. .. 11s. 4d.—13s. 4d. "
" Salicylate .. 10s. 2d.—12s. 2d. "
" Subnitrate .. 10s. 9d.—12s. 9d. "
Borax B.P. .. .. Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides .. .. .. Unsettled. Spot supplies short. Raw materials dearer. Market advancing.
Average spot values:—
Ammonium .. 1s. per lb.
Potassium .. 10d. per lb.
Sodium .. 11d. per lb.
Calcium Lactate .. .. Demand active. Good English make can be had from 1s. 7d. to 2s. 6d. per lb.
Chloral Hydrate .. .. 3s. 10d.—4s. per lb. Very firm and scarce.
Chloroform .. .. 2s. per lb. for cwt. lots. Very steady
Creosote Carbonate .. 6s. 6d. per lb. Little demand.
Formaldehyde .. .. £54 per ton, *ex* works. English make in casks. About 8s. per cwt. extra for carboys.
Glycerophosphates— Fair business passing.
Calcium, soluble and citrate free .. .. 7s. per lb.
Iron .. .. .. 8s. 9d. per lb.
Magnesium .. .. 9s. per lb.
Potassium, 50% .. 3s. 6d. per lb.
Sodium, 50% .. .. 2s. 6d. "
Guaiacol Carbonate .. 10s. 6d.—11s. 3d. per lb.
Hexamine .. .. 3s. 6d. per lb. for English make. Market steady.

Homatropine Hydrobromide	30s. per oz.
Hydrastine hydrochlor ..	English make offered at 120s. per oz.
Hypophosphites—	
Calcium	3s. 6d. per lb., for 28-lb. lots.
Potassium	4s. 1d. per lb.
Sodium	4s. ,,
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 5d. per lb., according to quantity.
Magnesium Carbonate—	
Light Commercial ..	£30 per ton net.
Magnesium Oxide—	
Light Commercial ..	£75 per ton, less 2½%.
Heavy Commercial ..	£20 per ton, less 2½%.
Heavy Pure	1s. 6d.—2s. per lb., according to quantity. **Steady market.**
lenthol—	
.B.R. recryst. B.P. ..	50s. per lb. Weaker.
Synthetic	26s.—35s. per lb., according to quantity. English make. Strong demand.
lercurials	Market flat.
Red oxide	5s. 3d.—5s. 4d. per lb.
Corrosive sublimate ..	3s. 6d.—3s. 7d. ,,
White precip.	4s. 7d.—4s. 8d. ,,
Calomel	3s. 11d.—4s. ,,
lethyl Salicylate .	1s. 10d.—2s. per lb. Weak tendency.
lethyl Sulphonal ..	26s. per lb.
Ietol	11s. per lb. British make.
'araformaldehyde ..	2s. 10½d.—3s. per lb. Not very active.
'araldehyde	1s. 5d.—1s. 6d. per lb. in free bottles and cases.
'henacetin	6s.—6s. 3d. per lb. Price and demand steady.
'henazone	7s. 3d.—7s. 6d. per lb. A shade firmer. Forward prices higher.
'henolphthalein	6s. 6d. per lb. Ample supplies.
'otass. Bitartrate—	
99/100% (Cream of Tartar)	88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
'otass. Citrate	1s. 10d.—2s. 2d. per lb.
'otass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues heavy.
'otass. Metabisulphite ..	7½d. per lb., 1-cwt. kegs included.
'otass. Permanganate .	7d. per lb. Keen competition keeps price low.
)uinine Sulphate ..	2s. 3d. per oz., in 100 oz. tins. Very heavy demand.
tesorcin	5s. 6d.—5s. 9d. per lb. Firmer. Scarce.
accharin	63s. per lb., in 50-lb. lots.
alol	3s. 6d.—3s. 11d. per lb.
ilver proteinate	9s. 6d. per lb.
'od. Benzoate, B.P. ..	2s. 6d. per lb. Ample supplies. B.P. quality available.
od. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity.
od. Hyposulphite—	
Photographic	£13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
od. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
od. Nitroprusside ..	16s. per lb. Less for quantity.
od. Potass. Tartrate (Rochelle Salt) ..	75s.—82s. 6d. per cwt., according to quantity. Steady market, good demand.
Sod. Salicylate	Market more active. Powder 2s. 2d.—2s. 4d. per lb. Crystal at 2s. 1d.—2s. 6d. per lb. Flake 2s. 9d. per lb.
Sod. Sulphide—	
Pure recryst.	10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Thymol	18s. per lb. Very scarce indeed. Still rising. Forward quotations 22s. per lb.

PERFUMERY CHEMICALS

Acetophenone	12s. 6d. per lb.	
Aubepine	15s. 3d. ,,	
Amyl Acetate	2s. 9d. ,,	
Amyl Butyrate	6s. 9d. ,,	
Amyl Salicylate	3s. 3d. ,,	
Anethol (M.P. 21/22° C.)	4s. 6d. ,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 10½d. ,,	
Benzyl Alcohol free from Chlorine	2s. 10½d. ,,	
Benzaldehyde free from Chlorine	3s. 6d. ,,	
Benzyl Benzoate ..	3s. 6d. ,,	
Cinnamic Aldehyde ..		
Natural	16s. ..	Advanced.
Coumarin	20s. ,,	
Citronellol . ..	17s. ..	Again advanced.
Citral	10s. ,,	
Ethyl Cinnamate ..	13s. 6d. ,,	
Ethyl Phthalate	3s. 3d. ,,	
Eugenol	11s. ,,	
Geraniol (Palmarosa) ..	35s. ,,	
Geraniol	11s.—18s. 6d. per lb.	
Heliotropine	7s. 9d. ..	Advanced.
Iso Eugenol	15s. 9d. ,,	
Linalol ex Bois de Rose ..	26s. ,,	
Linalyl Acetate	26s. ,,	
Methyl Anthranilate ..	9s. 6d. ,,	
Methyl Benzoate ..	6s. ,,	
Musk Ambrette	45s. ,,	
Musk Xylol	14s. 6d. ..	Again cheaper.
Nerolin	4s. 9d. ,,	
Phenyl Ethyl Acetate ..	15s. ,,	
Phenyl Ethyl Alcohol ..	16s. ,,	
Rhodinol	57s. 6d. ,,	
Safrol	1s. 10d. ,,	
Terpineol	2s. 4d. ,,	
Vanillin	25s. 6d. per lb.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	15s. 6d. per lb.
Anise Oil	2s. 8d. per lb.
Bergamot Oil	19s. 6d. per lb.
Bourbon Geranium Oil ..	36s. 6d. ,,
Camphor Oil	75s. per cwt.
Cananga Oil Java ..	10s. 6d. per lb.
Cinnamon Oil, Leaf ..	6½d. per oz.
Cassia Oil, 80/85% ..	8s. 9d. per lb.
Citronella Oil—	
Java 85/90%	5s. 8d. per lb. Again cheaper.
Ceylon	3s. 7d. per lb. Again cheaper.
Clove Oil	7s. 6d. per lb. Dearer.
Eucalyptus Oil 70/75% ..	2s. per lb.
Lavender Oil—	
French 38/40% Esters	29s. per lb.
Lemon Oil	3s. per lb.
Lemongrass Oil ..	3d. per oz.

Orange Oil, Sweet ..	.. 13s. per lb.	Cheaper.
Otto of Rose Oil—		
Bulgarian ..	.. 35s. per oz.	
Anatolian ..	.. 26s. per oz.	
Palma Rosa Oil ..	.. 19s. per lb.	
Peppermint Oil—		
Wayne County	.. 21s. per lb.	
Japanese ..	.. 14s. 3d. per lb.	
Petitgrain Oil ..	.. 9s. 3d. per lb.	Cheaper.
Sandal Wood Oil—		
Mysore	.. 26s. 6d. per lb.	
Australian ..	.. 21s. per lb.	

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before Sept. 23rd, they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on August 7th.

I.—Applications

Davies. Rotary ovens. 17,117. July 17.

Davies. 17,351. *See* VIII.

Day. 17,221. *See* XIX.

Duncan. Furnaces. 16,811. July 11.

Hardinge. Dry-grinding apparatus 16,942. July 15.

Hulsmeyer. Production of non-oxidising steam. 16,888. July 14.

Hurrell. Production of colloidal suspensions. 17,211. July 17.

Lush, and Technical Research Works. Production of metallic catalysts. 17,061. July 16.

Magnet-Werk Ges. Eisenach Spezialfabr. fur Elektromagnet Apparate. Utilisation and treatment of waste material. 17,178. July 17. (Ger., 12.2.24.)

I.—Complete Specifications Accepted

8497 (1923). Peachey Process Co., Ltd., Shaw, and Parsons. Treatment of articles or material with gases. (218,715.)

9526 (1923). Hodson. *See* VIII.

9599 (1923). Thermal Industrial and Chemical (T.I.C.) Research Co., Ltd., Rider, and Watts Heating liquids by introduction into molten metal. (218,723.)

9875 (1923). Bateman. Separators employed for separating liquids of different density. (218,742.)

14,670 (1923). Thermal Industrial and Chemical (T.I.C.) Research Co., Ltd., and Rider. Apparatus for the heat treatment of materials. (218,807.)

II.—Applications

Both. Production of gas and/or vapour from hydrocarbons. 16,968. July 15.

Donald. Drying peats etc. 16,938. July 15.

Jansen. Distillation and/or cracking of hydrocarbon oils. 17,253. July 18.

Konig. 16,853. *See* XXIII.

Tausz. 17,072. *See* XII.

II.—Complete Specifications Accepted

760 (1923). Jackson (Koppers Co.). Coke-ovens. (218,690.)

9526 (1923). Hodson. *See* VIII.

13,569 (1923). McIntire. Retort furnace. (218,802.)

26,567 (1923). Wilputte. Coke ovens. (218,898.)

31,764 (1923). Rude. Carbonisation of coal and production of high-grade gas. (218,925.)

IV.—Applications

Bloxam (Akt.-Ges. fur Anilin-Fabrikation). Manufacture of dyestuffs. 16,954. July 15.

Ransford (Farbenfabriken vorm. F. Bayer und Co.). Manufacture of dyestuffs. 17,300. July 18.

V.—Applications

Bourcot and Regnault. Removing ink from printed paper. 16,943. July 15. (Fr., 19.7.23.)

Farbenfabriken vorm. F. Bayer und Co. Manufacture of artificial silk. 18,301. July 18. (Ger., 20.7.23.)

Haefely et Cie. Akt.-Ges. Manufacture of mica-coated fibrous material. 16,952. July 15. (Switz., 28.7.23.)

Naamlooze Vennootschap Nederlandsche Kunstzijdefabriek. Manufacture of artificial threads from viscose. 17,073. July 16. (Ger., 8.8.23.)

V.—Complete Specifications Accepted

25,273 (1923). Christoph und Unmack Akt.-Ges. Hardening the surfaces of fibrous materials. (205,494.)

29,586 (1923). Soc. pour la Fabr. de la Soie "Rhodiaseta. Manufacture of artificial threads. (218,913.)

VI.—Applications

Bedford. Dyeing wool. 17,331. July 19.

Dawson, Farrell, Roberts, and Smith. Scouring and bleaching textile fibres etc. 16,972. July 15.

VII.—Application

Miller and Williams. Preparation of water-soluble phosphate salts. 17,025. July 16.

VII.—Complete Specification Accepted

836 (1923). Cowburn. Production of concentrated sulphuric acid. (218,694.)

VIII.—Application

Davies. Fire-resisting materials for rotary ovens etc. 17,351. July 19.

VIII.—Complete Specifications Accepted

9359 (1923). Marks (Libbey Glass Co.). Melting glass. (218,718.)

9526 (1923). Hodson. Manufacture of basic bricks, furnace linings, retorts and the like. (218,720.)

9964 (1923). Gandin, and Dartmoor China Clay Co., Ltd. Bleaching kaolin etc. (218,747.)

IX.—Applications

Colley, and Hickman, Ltd. Production of road material from furnace slag. 16,817. July 14.

Fiorenza. Building materials etc. 17,177. July 17.

IX.—Complete Specification Accepted

10,064 (1923). Saunders. Synthetic mineral asphalt. (218,750.)

X.—Applications

British Aluminium Co., Ltd., Gwyer, and Phillips. Alloys. 17,359. July 19

Burgers. Treatment of pig iron. 17,277. July 18.

Lush, and Technical Research Works. 17,061. *See* I.

Naamlooze Vennootschap Philips' Gloeilampenfabrieken. Separating hafnium and zirconium. 17,203, 17,309. July 17, 18. (Denmark, 18.7.23 and 25.8.23.)

Western Electric Co., Ltd. (Western Electric Co., Inc..) Metallic compositions. 17,043. July 16.

X.—Complete Specifications Accepted

7258 (1923). Finspongs Metallverks Aktiebolag. Heating elements for electric rotating resistance furnaces for treating zinc powder. (195,610.)

19,485 (1923). General Electric Co., Ltd. Manufacture of alloys containing tungsten carbide. (213,524.)

657 (1924). Aktiebolaget Ferrolegeringar. Production of alloys poor in carbon and silicon. (209,742.)

XI—Application

Pehrson and Rowlands. Electric furnaces, kilns, etc 17,162. July 17.

XI.—Complete Specification Accepted

7258 (1923). Finspongs Metallverks Aktiebolag. *See* X.

XII.—Applications

Chemical Engineering Co. (Manchester), Ltd., Battersby and Spensley. Separation of oils or fats. 17,053. July 16.

Lush, and Technical Research Works. 17,061. *See* I.

Tausz. Purification of oils. 17,072. July 16. (Ger., 16.7.23.)

XII.—Complete Specification Accepted

29,210 (1923). Bollmann. Removing odoriferous substances from oils and fats. (218,910.)

XIII.—Complete Specification Accepted

12,969 (1923). Indurit Products Co., Ltd., and Fairgrieve. Production of articles of the phenol-formaldehyde condensation product type. (218,793.)

XIV.—Complete Specification Accepted

19,197 (1923). British Dyestuffs Corporation, Ltd., Lefebure and Hailwood. Accelerating the vulcanisation of caoutchouc. (218,854.)

XVI.—Complete Specification Accepted

25,538 (1922). Igawa, and Asahi Garasu Kabushiki Kaisha. Manures. (218,401.)

XVIII.—Application

Steffens. 17,261. *See* XX.

XIX.—Applications

Chitty, Jones, and Woodlands, Ltd. Heat treatment of flour. 16,837. July 14.

Day. Water-distilling apparatus. 17,221. July 18.

Howles and McDougall. Manufacture of insecticides, sheep dips, etc. 17,361. July 19.

Sim and Weir. Deaerating water. 17,032. July 16.

XX.—Applications

Clark (Knoll and Co. Chemische Fabrik). Manufacture of double compounds of dimethylxanthines, earth alkali, and salicylic acid. 16,886. July 14.

Fairweather (National Aniline and Chemical Co., Inc.). Production of -nitranisole. 16,920. July 15.

Steffens. Dehydration of alcohol. 17,261. July 18. (U.S., 16.8.23.)

XXIII.—Application

Konig. Process for continuously recording heat value of gas mixtures. 16,853. July 14. (Ger., 14.7.23.)

GENERAL NOTES

Official Trade Intelligence

The Department of the Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W.1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number: *Argentina:* Textiles (135); *British India:* Steel bars, wrought iron cotters, and gibs (Madras and Southern Mahratta Railway Co., Ltd., 25, Buckingham Palace Road, London, S.W. 1); *Canada:* Leather goods (B.X./1102); *Denmark:* Metals and Technical products (119); *France:* Oils, Fats and greases (121); Groundnuts (122); *Melilla:* Soaps (132); *New Zealand:* General machinery (111); *Rumania:* Tin, terneplates and chemicals (128); Electrical plant (129); *South Africa:* Textiles, cutlery and electro-plate (114); Chemists' and druggists' sundries (115); Steel tubes (A.X 1166); *Spain:* Oil seed, chemical manures and colours (130).

Trade Information.

The Ruths Steam Accumulator Co., Ltd, of Central House, 45, Kingsway, London, W.C. 2, announce that their steam accumulator, of which, owing to its interest for the chemical industry, a description was given in the July 25 issue of *Chemistry and Industry*, is now being made in this country. Those interested are invited to visit the company's stand (Nos. 291-292, Bay 24) in the Palace of Engineering in the British Empire Exhibition. The Ruths Steam Accumulator Company are the sole licensees for the British Empire for the manufacture and distribution of the Ruths Steam Accumulator.

The Half year's Trade of Great Britain

Imports at £88,501,452 show a reduction of £33,585,147 on the May figures and a decrease of £858,072 on June 1923. Exports are down on the previous month by £8,236,644 at a total of £62,024,238, which is a decrease of £859,321 on June a year ago. Imports for the six months of this year were valued at £598,423,937, an increase of £59,548,409 over the corresponding period of last year, which British exports totalled £388,464,802, a rise of £5,785,775. Figures of some of the items of interest to our readers are appended.

	Import (value c.i.f.) June, 1924 £	Inc. or dec. as compared with June, 1923 £	Export (value f.o.b.) June, 1924 £	Inc. or dec. as compared with June, 1923 £
Coal	463	− 563	5,728,045	−3,222,734

Notes on Books.—M. Murray's July list records the publication of "The Technical and Economic Possibilities of British Agriculture," by Sir Henry Rew and Sir John Russell; a new (sixteenth) edition of "Halliburton's Physiology"; "The Chemistry of the Radio-Active Substances," by Dr. A. S. Russell; "The Recent Developments of Physical Science," by W. C. Dampier Whetham, M.A., F.R.S.; and a number of Imperial Institute Monographs on Mineral Resources.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council of Pure and Applied Chemistry

which consists of Representatives from

The Chemical Society, the Society of Chemical Industry, the Association of British Chemical Manufactnrers, the Institute of Chemistry, the Society of Public Analysts, the Faraday Society, the Institute of Brewing, the Society of Dyers and Colourists, the Society of Glass Technology, the Iron and Steel Institute, the Ceramic Society, the Institution of Gas Engineers, the Society of Leather Trade Chemists, the Royal Photographic Society, the Mineralogical Society, the Biochemical Society, the Institute of Metals, and the Royal Agricultural Society.

VOL. 43 NEW SERIES | LONDON, AUGUST 8, 1924 | NO. 32

EDITORIAL

It is no easy task to trace the history of holidays; it may be conjectured that in old days when nearly everyone lived in the country it was desirable to collect at harvest-time all those whose energies could be usefully directed towards the hayfield or the cornfield. We imagine that our vacations are now regulated by schoolmasters and other educators of youth; they fix for us the times when we can leave the chargeable noise of this great town. Fortunately for us the time which suits the schoolmaster for a trip to Brittany or Scotland equally suits the average chemist, and it is the time of year when the great towns are most unendurable and the country most delightful. Mothers, nurses and young children hasten to modern seaside resorts where outrageous prices are paid for uncomfortable and inartistic rooms facing a dreary patch of shingle, wet sand, or muddy sea. Every time we are persuaded that it is good for our body or soul to visit the coast of Norfolk, Suffolk or Essex we exclaim, either inwardly or aloud, in the words of Charoba:

"Is this the mighty ocean? is this *all*?"

The man, of any age from sixteen to sixty, who works in a town, if he possess a soul or an approximation to one, yearns for the country. Those who from early childhood have frequented mountains, hills and dales can never, even in London, quite forget them. They see, a mountain ascending, a vision of trees; bright volumes of vapour through Lothbury glide, and a river flows on through the vale of Cheapside!

* * *

How full are the old authors of references to the glades, springs and rivers, the wooded hills and tufted mounds which delighted the toil-worn Roman. It seems to us that every chemist who loves his science must long in August and September to go to a district where chemistry, as most of us imagine it, has no part. Of course, we all know the chemistry of agriculture is most fascinating and difficult, but it is not the study of this which drags us away from our chains and fetters, our retorts and our flasks. Give us an old country town or village whose houses were chiefly built in the seventeenth or early part of the eighteenth century; it is better they should be of stone with stone roofs; let us have a village green or a spacious square with a crazy old church clock and the bewildered chimes, as some poet calls them; a pastoral country is best where men talk of the breed of bullocks; it is an additional advantage if it is a cheese-making district. There let us ruminate, let us climb some local eminence and look round on a dozen counties spread out for our delectation; let us hear the lark, the peewit and, best of all, the curlew or the golden plover, and we can endure for a further spell our town existence. Call it not life. Some little care must be exercised in the choice of an inn or a hotel; it must not be too luxurious, too like the Carlton or the St. Pancras; we wish to have the country, not to move our town home to a distant spot. We like a hearth, for even in August and September we have been grateful for a fire; running water hard by is pleasant, but are not all these adjuncts described by many a philosopher?

Sit non doctissima conjux:
Sit nox cum somno; sit sine lite dies.

Let us have a daily newspaper, a local one is the best, and let our only scientific pursuit be the collection of reports of presidential addresses to the British Association to be read when we return to town.

We desire no alternate polarities or steam superheaters with us; time was when we could judge a field of oats before it was cut, or after it was threshed; we aspire to this again, but any other perfectly useless piece of knowledge is equally suited to a vacation. It is good to take a Virgil or a Martial with you to the country, or a volume of Anatole France or Coppée; it is also good to bring them back unopened. It is a sign your holiday has done you some service. If you return with a few pieces of rock or mineral wrapped up in fragments of the *Craven Herald* or the *North Oxfordshire Gazette*, let that also be to your credit. *O rus, quando ego te aspiciam?*

* * *

We have made a sort of exception in favour of the meetings of the British Association. It is nearly a hundred years since Sir Humphry Davy, Charles Babbage, Playfair, and most of all, Sir David Brewster, began an agitation for the co-ordination of British Science. In conjunction with the Yorkshire Philosophical Society and its secretary, John Phillips, a meeting was held in York in the year 1831, when the British Association was brought into existence. Mr. O. J. R. Howarth, in his pleasant retrospect published a couple of years ago, quotes from Brewster passages which bear some resemblance to others of more recent date: speaking of England Brewster said: "Bribed by foreign gold, or flattered by foreign courtesy, her artisans have quitted her service—her machinery has been exported to distant markets—the inventions of her philosophers, slighted at home, have been eagerly introduced abroad—her scientific institutions have been discouraged and even abolished." Brewster blamed everybody, our learned societies, especially the Royal Society, the ignorance and supineness of the Government, and the injudicious organisation of our scientific boards and institutions, and so on. We can almost imagine—but the British Association was founded and flourishes yet. The address of Sir Robert Robertson shows us that the Government's neglect of science is not so scandalous as it was a century ago. If anyone in holiday mood is inclined to be pessimistic, let him read the words of Brewster; he will wonder whether there was some inherited taste for criticism, some inherent desire to point out to all and sundry what stupid people they were; did not some such spirit dominate Ruskin and Carlyle? "Ye would be fools and victims and ye are." Sir Robert Robertson shows us how first one Government department, and then another, found out the need for chemical assistance in the interest of revenue, or health, or efficiency in offence or defence. A reference to his chart, which will be published in next week's issue, brings this home to us very forcibly, and we suppose that during the next fifty years the growth of Government science will be at least as great as during the previous hundred and fifty. The lack of organisation of our scientific institutions is not so striking as it was, and many of our present chemists are determined to improve the organisation of their science at an early date. It is a task which awaits those now on a holiday. But in the meantime let them enjoy their sunny shores, their flowery meads, with no thought of the morrow.

CHEMISTRY AND THE STATE *

Address by

SIR ROBERT ROBERTSON, K.B.E., F.R.S.

Introduction

It should be premised that in this account of the relationship of the State to chemistry in Great Britain, an attempt has been made to limit it to a description of the more or less direct assistance given by that science to various departments as they came into being or took form. Only in recent years, and as a result of the war, has there been a direct recognition of a corresponding obligation on the other side.

It is obvious that it is to the universities, and, as was the case to a greater extent in the past, to private workers, that the great advances made by British chemists are due. Departmental requirements have, of course, reaped the advantage of these advances, but examples of important contributions to chemical knowledge emanating from the departments themselves are not lacking. The collected story of their connexion with the activities of the State may be worth reciting, if it should show the development of its appeal to chemistry, and illustrate the gradual breakdown of the view held by the chief of the tribunal before which Lavoisier came, that "the State has no need for chemists."

We will find that their employment in an official capacity was in the first instance in connexion with the State's pressing necessities, such as its defence, the regulation of its currency, and the collection of its revenue, all of them subjects warranting the maintenance of equipment and staff.

As the need for safeguarding the nation's health, well-being, and the quality of its food-supply became recognised, legislation followed, frequently based on the work of Commissions on which sat distinguished chemists of the day, and it became necessary to set up a State chemical department to assist in carrying this into effect.

For some time the science of chemistry had received a limited and vicarious assistance from State grants to the late Science and Art Department and to the universities, but it was reserved for the war to establish definitely and finally the position that the whole future existence of a State might and probably would depend on the existence of a flourishing and efficient chemical industry. This resulted in the definite steps of assisting the application of science to industry, and providing direct encouragement for workers in the purely academic field.

It is proposed, therefore, to sketch the development of the main chemical activities of the State, and to review the conditions in Great Britain in the hope that it may be of use generally to define the present position, and perhaps of interest to this Dominion in the present stage of its chemical development.

* Presidential Address before Section B of the British Association Meeting at Toronto

Defence—Explosives

It would appear that the importation of the technical process from abroad is no new thing, for it is stated that in 1314 gunpowder and guns were being imported into England from Ghent. Not only the material but the executant also appears to have been imported in the person of a John Crab, a Fleming, who took service with the English and supervised the guns and munitions used at Crécy. By 1338, cannon were mounted on board English ships of war, and in 1346 gunpowder was being supplied to the King. Although the manufacture of gunpowder is mainly a mechanical operation, variations in the composition which must have involved chemical experiment are recorded in such works as the "Fire Work Books" of that interesting class, the Master Gunners. In England, a Master of the Ordnance in 1447 is stated to have made 20 tons of gunpowder. This manufacture, however, early became stabilised, and the proportions of the composition underwent little change until the middle of the nineteenth century, when it was modified, but as freedom from smoke began to be demanded a new propellant of a type that could be produced only by chemists was evolved.

It is of interest that Faraday was employed by the War Office as Lecturer at the Royal Military Academy from 1829 to 1853, and on appointment took as his assistant James Marsh, whose name, associated with the process for determining arsenic, is so well known to chemists. Marsh received the gold medal of the Society of Arts for this work, and a silver medal from the Board of Ordnance for his discovery of the quill percussion tube for cannon, and further he devised some of the earlier types of time-fuse. Abel succeeded Faraday at the Academy and began his long career of activity as scientific adviser to the War Office, becoming War Department Chemist in 1854.

It is necessary to mention some of the important advances made by Abel and his staff, including Kellner and Deering. By pulping guncotton, he rendered it safe to handle and store; his researches on the properties of guncotton laid the foundation of later work on its stability and explosive properties; and his research (with Noble) on the behaviour of gunpowder when fired is an example of a thorough investigation. Abel was consulted also on subjects other than explosives, and in his laboratory were conducted experiments which led to the adoption in 1879 of the present close-test apparatus for testing the inflammability of oils, experiments on steels and the effect of foreign materials in them, experiments on dangerous dusts and on the cause of accidents in coal mines.

The work of Abel in rescuing nitrocellulose from the position of an erratic substance, liable to decompose and explode on storage, led to its use as a reliable explosive, not only for military purposes, but also in commercial compositions, such as sporting powders and blasting explosives.

When it became necessary to devise a smokeless propellant for the British Service, the chemical work was in the hands of Abel with his assistant Kellner, Dewar, and Dupré, and in 1890 this resulted in the recommendation for the adoption of cordite.

It now became necessary to extend the only chemical manufacture carried on at the Royal Gunpowder Factory, that of guncotton, by adding the manufacture of nitroglycerine, the technical handling of cordite, and plant for treating acids, and accordingly in 1891 a chemical manager of this section with a staff of chemists was appointed.

The chemical work carried out by the British Government for defence, both as to its immediate object and as to its reaction on the explosives industry of the country, is worth review. In such a review the position before the war may first be described. Propellant manufacture was seriously undertaken, the small quantity of high explosive used at this time being mostly obtained from private manufacturers. Guncotton, as has been stated, had been manufactured by Abel in a fairly stable form, and this explosive was chosen for the Service propellant cordite, together with nitroglycerine and mineral jelly, the mixture being gelatinised by acetone, so that in a plastic condition it might be squirted into the cords which give it its name. A close study was devoted to this manufacture in all its aspects; the processes of manufacture were greatly improved, and the dangers reduced.

The Royal Gunpowder Factory took its place as a model of an explosives factory, and afforded an example of what could be done by a State department in conducting a scientific manufacture with regard to improved technique, economy, and efficiency. Thus the method of nitration to produce guncotton was greatly improved in safety, freedom from fumes, and ultimate stability of the product, by the adoption of the process of downward displacement of the waste acids from the nitrated product by a layer of water; for nitroglycerine a displacement process by which the layer of that liquid, separating on the surface of the waste acids, was caused to overflow from the top of the vessel by introducing waste acid from a previous charge at the bottom, led to an increased safety and yield, and saved height in the erection of a factory; the chemistry of the process of guncotton boiling was worked out and placed on a scientific foundation; and acetone, which in the process of drying the cordite had been allowed to escape into the air, was recovered from the drying stoves and saved for further use. These advances in manufacturing method were taken up by other manufacturers, both in the United Kingdom and abroad.

In the technique of the manufacture of propellant explosives before the war this country then had advanced to a high pitch of efficiency, so that when the demand came for enormously increased quantities of propellants, new factories, such as that of Gretna, took up the manufacture on lines already well established.

Safety in manufacture had also been closely studied, and precautions introduced that commended themselves to private firms. It may be said in this connexion that the application of the Explosives Act of 1875 by the Home Office Inspectors of Explosives has been of much benefit to the explosives trade in reducing casualties. Perhaps in no other

country are precautions taken to such an extent as in Great Britain, so that to visitors from abroad they sometimes appear unnecessary and vexatious, but experience has shown that the policy is sound, especially as it brings into all sections of the work an atmosphere of carefulness and responsibility, with an eventual gain in health of the workmen and freedom from accidents.

Research on explosives before the war was carried out at the Royal Gunpowder Factory and at the Research Department, Woolwich. At the former establishment, the chemistry of the products manufactured was investigated, especially with regard to the mode of decomposition of guncotton, of nitroglycerine, and of cordite: their respective rates of decomposition at different temperatures were determined, a subject bearing on their behaviour on storage. Knowledge of this kind, is essential in a Service such as ours, on account of the extremes of temperature from tropical to frigid to which explosives may be subjected in stations throughout the Empire.

At Woolwich an experimental establishment had been set up on the instigation of Lord Haldane to deal with explosives and metals used in gunnery. Here the study of the chemical and explosive properties of all types of explosives was undertaken and methods were developed for determining their stability and sensitiveness. This knowledge found application in laying down criteria for the choice of explosives for use in a Service whose demands are exigent on account of the drastic conditions above mentioned, affecting both storage and the design of mechanism containing explosives. So far as the subject-matter is not considered to be confidential, this work has been published in scientific journals, so that it is available in connexion with the study of the theory of explosive substances.

A new phase was entered with the declaration of war, and ultimately all chemical help was mobilised for the defence of the realm. A nucleus existed at Woolwich, where the small staff of eleven chemists had been occupied in the study of explosives and their application. In two directions this experience proved of importance, for it enabled immediate answers to be given to questions which would otherwise have necessitated protracted storage trials, and it afforded the staff the training necessary to qualify them to meet the fresh demands that became urgent on the outbreak of hostilities.

After the beginning of the war the increase of work imperatively called for a larger staff, and more chemists were appointed, until at the beginning of 1917, the home supply being exhausted, permission was obtained to withdraw from France members of the Special Brigade, R.E., of whom more than thirty were transferred to the Department. Finally, the chemical staff numbered 107 chemists and physicists distributed in an organisation which had been gradually evolved, comprising sections for dealing with different classes of work, such as organic chemistry, physical chemistry, analytical and general chemistry, physical investigation, calorimetry, stability, pyrotechny, applications of high explosives, fuze design, and records.

The manufacture of high explosives had not previously been undertaken by Government, and the known processes for making trinitrotoluene, which was early chosen as a Service high explosive, were unsatisfactory. One of the first subjects, therefore, taken up after the outbreak of war was the provision of an efficient and rapid process for the manufacture of trinitrotoluene, especially without the use of fuming sulphuric acid (oleum). From the results of a large series of nitrations in the laboratory, a process was evolved characterised by several novel features, and this was put to the proof on the semi-industrial scale of a quarter ton, a plant being designed and erected in the Research Department, Woolwich, for nitration, including appropriate arrangements for the mixing and concentration of acids. This small plant substantiated in a remarkable way the process evolved from the laboratory work, and from the start turned out trinitrotoluene of good quality and yield. The process found immediate application in the large Government factories that were designed and erected by Mr. Quinan and also in numerous private works built at this time. The small-scale plant mentioned was used also for the purpose of training chemists, who proceeded to operate chemical plant in Government and private factories.

A study of trinitrotoluene in all its aspects was undertaken, and much attention devoted to its chemistry, the proportions in which the isomers occur in the crude product being determined by thermal analysis, and investigations were made on their interactions, stability, sensitiveness, heat values and explosive properties. Most of the scientific results of this work have since been published.

When it became evident, as it soon did to Lord Moulton, that the supply of high explosives in use, lyddite and trinitrotoluene, would not suffice, the Research Department put forward mixtures of ammonium nitrate and trinitrotoluene, the amatols, as a result of a study of their properties and of their effects in shell-bursting trials. Gun trials confirmed these trials at rest, and the adoption of amatol as a high explosive quickly followed. Various methods of filling these mixtures into shell were at this time worked out, and many of them were applied on the very largest scale.

It was found that 80/20 amatol (80 parts of ammonium nitrate to 20 of trinitrotoluene) was less easy to bring to detonation than lyddite or trinitrotoluene itself, and it required special arrangements in the train of initiation of detonation. These were successfully devised, and good and trustworthy detonation of our shell was secured. Ultimately, amatol became practically the only explosive for land and aerial warfare, and justified the early estimate of its properties and capabilities. It is economical in that it makes use of a cheap ingredient, and has explosive properties that render it very suitable for the purposes for which it is used. In 1917 the production was at the rate of about 4000 t. a week.

The Department continued the study of amatol, especially with regard to its chemical stability and

compatibility with the various materials with which it came into contact. Certain impurities in ammonium nitrate were discovered to be objectionable, and investigation of these led to an improvement in the purity of the ammonium nitrate supplied. The manufacture of amatol and the modes of filling it into shell occupied the attention of a large staff of chemists attached to the factories, and an increase in knowledge of its chemical and physical properties led to improved methods of handling it.

The Service propellant cordite required for gelatinisation in the course of its manufacture the solvent acetone, of which the supply ran short when the programme for propellants began to exceed all previous calculations. To meet this situation, cordite of the existing type was retained for Naval Service, but for Land Service a modification was introduced under the name of cordite R.D.B. (Research Department powder 'B'). This propellant could be made without any alteration in the plant required for the manufacture of cordite. Instead of acetone the solvent employed was ether-alcohol, and instead of guncotton a lower nitrate of cellulose was used. The great factory at Gretna, also built by Mr. Quinan, manufactured cordite R.D.B. exclusively, and this soon became the only propellant made in this country for the Land Service. It was produced both by Government and by private firms in enormous quantities. The alcohol was made in the country from grain, and other was produced from it, so that dependence on sea-borne solvent was reduced. It was this need for alcohol that led to the restrictions imposed on that liquid when used as a beverage.

Numerous problems arose in connexion with these manufactures as they developed and in the application of the explosives in the various types of ammunition, and these necessitated the study of the explosives in all their aspects. A large addition to the knowledge already existing was thus acquired on the more theoretical side of the study of explosives, and much of this has been made available by publication.

As the demand on our resources increased, and the necessity grew for investigating every source of supply and possible alternative, it came to pass that nearly every professor of chemistry in the country was mobilised for investigation in this field and in that of chemical warfare, and much valuable work was done by them, both of a research and inspectional nature.

For the manufacture of explosives and the operation of filling them into munitions of various kinds in the existing factories and the new ones which sprang up, a large staff of chemists, amounting to about 1000, was required, and in this way many chemists whose earlier work lay in quite other directions, such as at the universities or in teaching posts, received an insight into technology and took control of workmen.

During the war itself, instructional work in this subject was not wanting, for current progress in the factories under his control was discussed in a systematic manner by Mr. Quinan with representatives of his staff, a course which led to important improvements. Although most of these war-time plants for the manufacture of explosives have been dismantled, much of the technical experience gained has been saved, and will be found incorporated in a series of memoirs (Technical Records of Explosives Supply) published by H.M. Stationery Office. The information set forth in these volumes is in a form which has a much wider appeal than to the explosives technologist only, and their study is commended to those who take up the subject of chemical technology in any of its aspects.

In addition, factories for the production of substances not in themselves explosive equally required the services of chemists, and many were employed in the production of such substances as methyl alcohol, acetone, and acetic acid.

Instruction in chemistry is provided by the Fighting Services for Naval and Marine cadets at Dartmouth, and for Army cadets at the Royal Military Academy and the Royal Military College, Camberley. For selected officers, both of these Services have a professorial staff for providing systematic courses in theoretical and practical chemistry, with special reference to Service applications, at the Royal Naval College, Greenwich, and at the Artillery (formerly the Ordnance) College, Woolwich.

Defence—Chemical Warfare

While our well-developed position of the great inorganic chemical manufactures was a source of strength when the demand came during the war for an enormous production of ammonium nitrate, for example, our neglect to foster a great organic chemical industry led to dangerous delays and improvisations. This was apparent from the beginning when several universities had to co-operate to produce a sufficient supply of local anæsthetics, and when presently our lack of dyes, photographic developers and sensitisers revealed our former dependence on foreign supplies. In November, 1914, the Royal Society had set up a Committee to assist the Government, and this became an Advisory Committee when, after May of the following year, the gas attack caused the British Government, which up till then had scrupulously refrained from its use, to retaliate with that weapon. Special companies were created of chemists whose work often had little of a chemical aspect, but many of these men, in twelve to eighteen months, had to be withdrawn for research and control of plant. Chemical advisers were appointed to the armies and for liaison purposes, a central laboratory for rapid identification was established in France, and co-operation was effected with the physiologists. At home assistance was afforded to chemical contractors, and the manufacture of respirators to meet needs rapidly becoming more complex was carried out with great vigour and efficiency. The increasing importance of gas warfare led to a proving ground at Porton being acquired, when the research which had been carried out at the Imperial College at South Kensington became centralised there. As the final proof of explosive projectiles is carried out at Shoeburyness, it was now possible on this new proving ground to settle questions relating to the filling and correct performance of chemical shell, thus enabling the Chemical Warfare Designs Committee to recommend ammunition to meet the

needs of a situation which was continually developing, until the proportion of chemical shell compared with high explosive shell was finally a large one.

In the ramifications of this work all the chemical skill in the universities not already applied to explosives was mobilised, since the demand for new designs involved the manufacture of new substances for shell, bombs, and grenades, new smoke and incendiary compositions, and continuous research and experimental work both on the offensive and defensive sides.

In a few cases only was the country capable of expanding its existing manufactures, as in the case of phosphorus and chlorine; it was not equipped for the home production of phosgene, arsenical compounds, or mustard gas. New factories had, therefore, to be erected and staffs specially trained, in striking contrast to the existence in Germany of standardised plant capable of rapid transference from one purpose to another with little alteration; an example of this was their manufacture of arsenical preparations in the azo-dye sheds.

As a result of an intensive study of absorbent substances, our respirator was never beaten, and it is claimed that, although our output was smaller, the better employment of gas, tactically for surprise, lay with us. Starting late and entering a field entirely new, we were able while there was yet time to protect the soldier, and to make a reply on the offensive side that was rapidly becoming more and more effective.

Not all of the work specially devoted to chemical warfare has been without its effect on peace-time requirements. Thus liquid chlorine, of which very little was made in this country before the war, is now being prepared electrolytically and transported by rail in tank waggons for use in various industries. For the preparation of phosgene, which had been used in Germany in the manufacture of dyes of the triphenylmethane series, better methods were discovered in this country, so that cheaper and purer phosgene is being used here for the first time to prepare the important group of colours known as the Victoria blues. Improved methods are now available for the manufacture of arsenical compounds, such as arsenic trichloride, a substance used for combating the growth of prickly pear in Australia; and mention may be made of the work of Prof. Moureu in France, on the stabilisation and concentration of acrolein, as it has led to the production of a substitute for celluloid from that body. In addition, the study of many of the bodies used for chemical warfare has been of value from the aspect of the elucidation of their chemical constitution.

Metallurgy

When the part played by metals in the history of civilisation is considered, the development of some more durable alloy or some stronger metal appears intimately linked with a distinct advance, constituting a new age, often characterised by eponymous association with the metal. As the possession of some superior metal may give ascendency to a people, it is natural that States should show interest in metallurgy, both militarily and to maintain the standard of the medium of exchange. It is thus seen that iron and the precious metals, gold and silver, have for the most part interested the modern State, the metallurgy of the other metals only more recently coming in for attention on military grounds. Accordingly, we find the armourer and the minter holding important positions in early times.

It must be stated at the outset that the relations in Great Britain between the State and metallurgical science before the war of 1914 to 1918 were for the most part sporadic, the great developments in that science being to a large extent independent of the State. It undoubtedly exerted, however, an influence on the nature and quality of metallurgical products, of which it was a large user for warlike, structural, and shipbuilding purposes, by specifying the conditions of their acceptance: standards established by the Government, often based on enquiry and experiment, gave confidence to other users and resulted in the improvement of industrial materials.

Although iron-making had flourished intermittently since the Roman occupation, and had reached considerable proportions under Elizabeth, no great contribution to knowledge can be attributed to Great Britain in the progress of metallurgy until the restriction of the cutting down of timber for charcoal towards the end of the sixteenth century forced into consideration the use of coal for smelting, the pioneer work being that of Dud Dudley, who in 1642 cast iron cannon at his foundries for the Royalist troops. It was his experience as an Admiralty official that brought Cort, more than 100 years later, to recognise the inferiority of English wrought iron, and to leave the Service for the purpose of improving existing processes so that his successful wrought iron was accepted towards the end of eighteenth century for anchors and iron wor the Royal Navy. His invention of the pu process led to great prosperity in the iron trade.

The need to meet Government requirements became similarly urgent in the case of steel, which in its earlier production as puddled steel so failed in uniformity of composition that as a materi of construction it could not be used by the Admiralt nor permitted by the Board of Trade. Bessemer's great advance of converting molten iron cast into steel by blowing air through it, described in 1856 to this Association, enabled him to propose a material more suitable for guns and projectiles than the cast iron then employed. Bessemer steel came into use for many purposes, and its production increased rapidly, but boiler plates submitted to the Admiralty still showed great variations in carbon content. Meanwhile the rival open-hearth process was steadily developed and established by Siemens. In 1875 the Director of Naval Construction had pointed to the danger due to lack of uniformity of steel made by the converter process, but in 1879 he was able to report the success of the new open-hearth steel. The Government challenge had been taken up by Siemens, who produced a steel to meet all its specifications, so causing its acceptance for Admiralty work, and its admission by the Board of Trade for structural use.

After Thomas and Gilchrist had in 1877 solved the problem of dephosphorising iron by the basic

process, the Admiralty instituted an enquiry as to its properties, which led to an official recognition of basic steel, thus greatly enlarging the source of supply through the use of native ores.

Among the men who assisted the Government in these enquiries was Dr. Percy, who placed metallurgy in this country on a scientific basis, while lecturing on that subject at the Royal School of Mines and at the Ordnance College. Abel, appointed War Department Chemist in 1854, gave much attention to the use of iron and steel for military purposes, investigating the question of erosion of guns and throwing new light on the constitution of steel by his isolation of Fe_3C. He did good service in convincing the great ironmasters of the importance of chemistry in their industry. To Roberts-Austen also, Chemist and Assayer to the Mint, many Government inquiries and commissions were indebted for advice on the subjects he had enriched by his researches, such as the physical constants and mechanical properties of metals, the effect of impurities, the cementation of iron, heat treatment, and many others, including the first "freezing-point" curve of a series of binary alloys in 1875. It was in consequence of these that his co-operation was invited by the Alloys Research Committee, whose first six reports contained a great deal of his work, covered a wide field, and did much towards the realisation by engineers of the value of microscopical and thermal methods in the study of metals. Later reports to this committee, whose work in 1902 was transferred to the National Physical Laboratory, have maintained their high standard, and have been contributed to by such workers as Carpenter, Hadfield, and Rosenhain.

The last of these reports, the eleventh, embodies work at the National Physical Laboratory from 1914 to 1918, the year when that Institution became a part of the Department of Scientific and Industrial Research. It deals with light alloys, the need for which the war has emphasised, especially in connexion with aircraft. For this purpose the Laboratory's work has resulted in furnishing alloys of aluminium with zinc and copper, with copper and manganese, and with copper, nickel and magnesium, possessing remarkable and useful properties, such as high tensile strength at ordinary and also at raised temperatures.

Since the war light aluminium alloys continue to be studied at the National Physical Laboratory, which is the Government establishment where metallurgical research is carried out mainly for the advancement of knowledge. Here has been worked out the constitution of many important systems, binary, ternary, and quarternary, in which aluminium is the largest constituent, and the wire models constructed for the ternary alloys have proved of great value in the study of their constitution. Such questions as age-hardening have been investigated and the cause ascertained.

Systems with copper as the dominant metal have been investigated as regards their constitution, as well as the effect on their mechanical and electrical properties of known additions of other substances that may be present as impurities.

But attention is also being given to ferrous alloys for whose investigation specially pure components have to be prepared, in order to eliminate the effect of impurities of which a very small proportion may often have a marked influence on the product, and several equilibrium diagrams with iron as the main component have been worked out. Research on the more physical side includes investigation on the heat evolved during the plastic deformation of a metal, on the effect of heat treatment and composition on the magnetic properties of tungsten steels, on fatigue, and on the physical constants of metals. By the application of X-ray analysis to the crystal structure of metallic systems, Rosenhain has obtained confirmation of his conception of the nature of solid solutions.

The chemical section of the National Physical Laboratory carries out a large amount of work in connexion with these researches, the investigation of methods of analysis, and the preparation of standards for the analysis of steel, as well as chemical work of a non-metallurgical nature.

Maintained by the Fighting Services since 1904 to increase the efficiency of the metals used in the manufacture of ordnance and armament, the Metallurgical Branch of the Research Department, Woolwich, increased in numbers, building and equipment during the war, and at present employs about 25 metallurgists. It has been occupied for the most part with steel, the heat treatment of which in relation to its mechanical properties has been the subject of close study, resulting in improved gun forgings being delivered by the makers. Two main types of steel have been under consideration, those which would give a minimum yield point of about 35 tons per square inch when treated in large masses, and those at about 25 tons. As a result much information has been acquired on the properties and heat treatment of steel containing various proportions of nickel, chromium, molybdenum and vanadium. The study of the elastic properties and of the erosion of gun steel has been of importance to gunnery. The Moore adaptation of the Brinell hardness test, in which a small ball and load are used in a specially designed machine, was originally developed in the Department for testing small arm cartridge cases, and has since found many other important applications here and elsewhere.

Among other investigations on non-ferrous metals, those on "season-cracking" of brass and its prevention, and on methods of extrusion, have been productive of useful results, and in connexion with the Non-Ferrous Metals Research Association, work is in progress on the casting of brass to produce sounder ingots, on the die-casting of brass and bronze, and on the failure of lead cable sheathing by cracking.

During the war, the use of substitutes, the easing of specifications to increase output with safety, the examination of enemy ammunition, and the tracing of causes of failure and discovery of remedies provided a large field for investigation.

The other aspect of metallurgy of special interest to the State, that of minting, has a long history:

from early times the need for a high and uniform standard of coinage, and the crime of debasing it, have been recognised. The difficulties that confronted the early assayers, without methods of quantitative analysis and with no fine balances, are apparent from the description of their methods, but it may perhaps be held that these needs as they became borne in on the early assayers and their frequent collaborators the alchemists, led the way to the appeal to weighing in chemical work.

As early as 928 A.D. laws were proclaimed by King Athelstan appointing 'mynteres' whose products were scrutinised at the trial of the pyx; later, in 1180, supervisors of the coin manufactured by 'moneyers' were appointed.

An official mention occurs in the reign of Edward I of a Guild of Goldsmiths in London, which had, however, existed since 1180, in an Act providing for the assay of silver vessels by the Wardens of that craft. The earlier writings on the subject of assaying are those of Germans, of whom Queen Elizabeth brought over a number to introduce their methods and assist in the development of the resources of the country.

The course of testing seems to have been originally by means of the touchstone, supplemented much later by observing the effects of acid on the trace left by drawing the metal over the stone, the method of determination of density, the cupellation method, officially recognised by Henry II, and finally the wet method of analysis.

To safeguard the fineness of the coinage a King's Assayer was appointed in 1222, a Master of the Mint manufacturing the coin under contract, and a Warden acting on behalf of the King. A Commission, having toured the Continental mints, reported in 1870 in favour of the present organisation of the Chancellor of the Exchequer being Master of the Mint in virtue of his office, a Deputy-Master being responsible for the administration, while the valuation of bullion and questions of assay are the duties of the Chemist and Assayer.

Many of the Mint officials have contributed largely to metallurgical knowledge. One of them, William Humphrey, in 1565 received the first patent for making brass, and a later one, Sir John Brattle, communicated work to the Royal Society shortly after its foundation on the oxidation of lead. Sir Isaac Newton when Warden is said to have himself conducted experiments on the composition of foreign coins. The melting-points of metals were studied in conjunction with Wedgwood by Alchorne, who was appointed Assay Master in 1789. From 1851 to 1870 several distinguished men of science, such as Hofmann, Graham (who in 1866 published a work on the effect of the occlusion of gases in metals), Miller, and Stenhouse, were officials of the Mint; but in 1870 it was considered preferable to conduct the chemical operations of assaying within the Mint itself, and Roberts-Austen, to whose pioneering work in metallurgy allusion has been made, was appointed. To his successor, Kirke Rose, are due many advances in knowledge of the precious metals. Thus, researches at the Mint have been directed to the investigations of metallic systems of gold with silver and other metals, the means of avoiding brittleness in gold coins, the electrolytic refining of gold, the mechanism of annealing of metals, the surface tension of solid and molten metals, as well as to improvements in the technique of the methods of assay.

Revenue

In reviewing the influence of our science in its application to Revenue questions, it is convenient to consider historically the substances on which the State has levied duties.

In the older tariffs, fixed charges were levied on goods considered as a whole, but a time arrived when the chemist was called in; it then became possible to make an assessment on the ground of a percentage. Uncertainty prevailed, therefore, as to the basis of taxation and gross adulteration flourished until scientific safeguards were introduced.

The chief substances with which the chemist is at present concerned from the Revenue point of view are the following:—(1) liquids containing alcohol; (2) tobacco; (3) sugar; (4) tea and cocoa; (5) dyestuffs, under the Dyestuffs (Import Regulation) Act, 1920; (6) substances under the Safeguarding of Industries Act, 1921.

(1) *Liquids containing alcohol.*—On imported wine Richard I imposed a duty, and as time went on complications were caused by the introduction of imposts for various purposes, including reprisals.

Acts were passed, as in the time of Charles II, for preventing the reprehensible practices of mixing wine and vitiating it with other substances such as cider, sugar, herbs and vitriol; it is still forbidden to mix wines of different sorts.

The difficulty of distinguishing the strength of alcoholic liquids is apparent in the older enactments, when, for example, the Legislature describes brandy as a "strong water perfectly made imported from beyond the sea," and it was not until the reign of William III that they were assessed, if not in proportion to their strength, at least in some relation thereto. The first step was their separation into 'single' and 'double' proof, a rough and inconclusive one, but accounting for the use of a term still recognised as that on which the full statutory rate of duty is leviable.

For charging Revenue the gallon was first taken as a measure in 1825, but definite alcoholic strength was not introduced as a basis until 1860, under a treaty with France, while a little later, in 1862, Parliament distinguished between wines above and below 26 degrees of proof spirit, this figure being raised in 1886 to 30 degrees.

The want of some accurate method of test had been felt, and it is interesting to follow the gropings after a method for recognising a standard strength of alcohol. Thus observations on the surface tension of spirits were employed, for Postlethwaite in 1751 described as a mark of their being up to proof the length of time elapsing before bubbles disappear from the surface of the liquid contained in a glass tube which had been shaken, but as he believed this method may be falsified, he recommended for more accurate work "the essay instrument, or hydrostatical balance," although for

business men it would be sufficient to burn a measured quantity of the spirit in a metal cylindrical vessel immersed in cold water, and measure the remainder, which should be equal to half the original volume, if the spirits were proof. Although "Boyle's bubble" had been described in 1675, and Monconý's areometer in 1679, the first instrument generally adopted by the Revenue in 1730 was the hydrometer of Clarke, legalised in 1787. It is complicated, however, and its temperature correction by "weather weights" was unsatisfactory, so that Parliament gave instructions for "proper experiments to be made."

At the request of the Government to the President of the Royal Society, Sir Charles Blagden (secretary) and one of the clerks, Mr. George Gilpin, undertook to make experiments on the specific gravity of alcohol and water in varying proportion. These experiments, conducted with exemplary care and ability, were reported to the Royal Society in 1790, 1792 and 1794, and formed the basis for the tables of Sikes, whose hydrometer became the sole legal instrument in 1818, and is still in use. These tables remained legal for nearly a hundred years, but in 1916 were replaced by a new and extended set, prepared under the supervision of Sir Edward Thorpe at the Government Laboratory, whence also in the same year were issued comprehensive tables of spirit strengths for use with pyknometers, as these had shortly before been legalised for alternative use in the determination of alcohol. Both of these sets of tables were founded on the definition of proof spirit contained in the Act of George III, which is, that spirit which at the temperature of 51° F. weighs exactly 12-13 parts of an equal measure of distilled water. In other words, it contains 49·28 parts by weight of pure alcohol and 50·72 parts by weight of distilled water.

As these tables refer only to alcohol-water mixtures, all disturbing substances must be removed before the strength of liquids is determined by hydrometer or pyknometer. The methods of freeing spirit in commercial articles from everything but water were investigated and laid down by the Government Laboratory in 1903 by Thorpe and Holmes.

From the point of view of trade it is highly important to have free use of ethyl alcohol, while from that of the Revenue it is essential to prevent the use of such duty-free spirit as a beverage. The most effective means to meet both requirements is to denature spirit which is to be delivered duty-free for trade purposes, and the question of the choice of a suitable denaturant is by no means easy. So long ago as 1856, the Government Chemist of the day, Mr. Phillips, proposed the addition of 10 per cent. of crude wood naphtha, and this has been found satisfactory for most purposes. The proposal was submitted to and approved by three well-known chemists of that day, Graham, Hofman and Redwood, and this present year circumstances have necessitated the addition of a further nauseating ingredient, pyridine, in addition to mineral naphtha which was added in 1891. Mineralised methylated spirit which is sold without Revenue control, excepting that a licence is needed, contains this proportion, industrial methylated spirit 5 per cent., and power alcohol $2\frac{1}{2}$ per cent. on the alcohol.

That some misunderstanding exists as to the facilities available for the use of alcohol in commerce in the United Kingdom appears from an article recently communicated to the Ottawa Section of the Society of Chemical Industry, in which are contrasted a considerable number of compositions approved in Canada with the apparently small number legalised in Great Britain. It might be well, therefore, briefly to indicate the position, in order to make clear the facilities that are available.

Mineralised methylated spirit consists of a mixture of 90 parts of alcohol, $9\frac{1}{2}$ parts of wood naphtha, and half part of crude pyridine, together with $\frac{3}{8}$th of 1 per cent. of mineral naphtha and 0·025 of an ounce of methyl violet dye in each 100 gallons of the mixture. It is sold under licence, but is otherwise unrestricted and duty-free.

Power methylated spirit, prepared in accordance with the following formula: 92 parts of alcohol, 5 parts of benzol, 0·5 part of crude pyridine, and 2·5 parts of wood naphtha, together with 0·025 of an ounce of Spirit Red III dye in each 100 gallons of the mixture, is also sold without restriction and freedom from duty when mixed with 25 per cent. of hydrocarbons or denatured ether or some other substance approved by the Commissioners of Customs and Excise.

Industrial methylated spirit, consisting of 95 per cent. of ethyl alcohol and 5 per cent. of wood naphtha, can be obtained for the arts and manufactures under the authority of the Board of Customs and Excise, under bond and certain not very onerous restrictions. Between three and four million bulk gallons are annually used for the making of such products as varnishes, linoleum, soap, solid medicinal extracts, ether, toilet preparations for external use, fine chemicals, photographic plates, dyes, surgical dressings, fireworks, and for many other purposes, including its use in the chemical laboratories of colleges, schools and works, and for preserving museum specimens. It is free from duty, but must not be present in an article capable of internal use, either as a beverage or a medicine.

Duty-free pure alcohol is allowed by the Board of Customs and Excise for scientific purposes to universities and public institutions for teaching and research, and specially denatured alcohol in arts and manufactures in which the use of the industrial methylated spirit is unsuitable.

The pure alcohol is allowed to colleges and public institutions for teaching and research purposes without any onerous conditions beyond the keeping of a stock account. Pure methyl alcohol is permitted by the Board of Customs and Excise to be used duty-free in arts and manufactures under regulations similar to those for industrial methylated spirit, and is largely used in the manufacture of formaldehyde, of methyl derivatives among dyestuffs and fine chemicals, and for the purpose of crystallisation.

The specially denatured alcohol, also free from duty, is allowed to manufacturers under restrictions

compatible with the safety of the Revenue, a very wide choice of denaturants being permitted. When, as frequently happens, a suitable denaturant is found in some intermediate product, or acid used, or produced during the manufacturing operations, or when the alcohol is a constituent of some mixed solvent, permission is the more readily granted for its use. An example of progressive policy in the use of pure spirit is the recent decision of the Board of Customs and Excise to allow the use of pure ethyl alcohol denatured with 2 per cent. of pure methyl alcohol in the production of insulin, without onerous Excise restrictions. It is understood that the recent action of the Board of Customs and Excise has been received with satisfaction by the Association of British Chemical Manufacturers. The quantity of pure and specially denatured alcohol used during last year was about half-a-million gallons.

In the case of duty-paid spirits used for medical purposes such as the preparation of tinctures, and for scientific purposes in chemical laboratories, a rebate is allowed under the Finance Act of 1920, amounting to about 80 per cent. of the duty.

While the responsibility rests on the Board of Customs and Excise of safeguarding the illicit use of alcohol, chemists have been represented on such commissions as that of the Industrial Alcohol Committee of 1905, whose recommendations led to the Revenue Act of 1906, in which the proportion of wood naphtha was reduced to 5 per cent., permission being also given for the payment of an allowance of 5d. per proof gallon or about 8d. per bulk gallon on British spirits used for industrial purposes, in consideration of the increased cost of the spirits owing to Excise restrictions.

An important alcoholic liquid that has been liable to imposts from the time of Charles II is beer, and it was charged according to its strength or weakness as judged by the palate. After the application of science to brewing about the middle of the eighteenth century, the saccharometer was introduced, the pattern due to Bate being still in use for Revenue purposes. In 1850 an investigation made by the then Government Chemist, Mr. Phillips, and his assistant, Mr. Dobson, established a quantitative relationship between the proportion of alcohol produced in the process of fermentation and the solid matter previously in solution in the worts that had been fermented, and tables were prepared for use in determining the original gravity of the beer, *i.e.*, the specific gravity of the worts before fermentation had begun. These tables, after verification by Profs. Graham, Hofmann and Redwood, were employed in the Revenue service until 1914, when they were superseded by revised ones prepared by Sir Edward Thorpe and Dr. Horace T. Brown, these being rendered necessary mainly owing to the employment in brewing of many substitutes for malt unknown in the earlier days. As a rapid means for determining the original gravity the immersion refractometer is constantly in use in the Government Laboratory. This laboratory also furnished the scientific evidence for the Inland Revenue Act of 1880, which enabled brewers to use a great variety of substances for brewing.

(2) *Tobacco.*—Not long after its introduction Elizabeth imposed a small duty on tobacco, which under James I met with not only his famous Counterblast, but an increased duty of 6s. 10d. a pound. Although Charles I continued its repression, and the Puritans regarded its use as "profanity," the snuff-box became in the time of Queen Anne a necessity of the fashionable world. A regular trade sprang up in preparing substitutes from various leaves, and numerous enactments proved incapable of preventing smuggling and adulteration. It was recognised that systematic chemical and microscopic examination had to be applied to the problems arising from this adulteration, and in 1843 a laboratory, which ultimately grew into the Government Laboratory, was erected to check it, with the result that this form of fraud was almost entirely stamped out. A strict watch is still maintained on all tobacco for home use or for export, both from the point of view of absence of foreign materials and of its hygroscopic condition, as the Revenue charge is based on the latter. Chemical control is exercised over the use of preservatives and the denaturing of tobacco before it can safely be allowed out of Revenue control.

(3) *Sugar.*—In the reign of James I the importation of sugar was already sufficiently large to make it worth while to impose a duty on it, until at the beginning of the nineteenth century this amounted to 30s. a hundredweight. Before 1875, when the duty was abolished, disputes had arisen as to its proper assessment on the basis of description and character. When it again became dutiable in 1901 an extended classification was based on the polariscope scale, and sugars in numerous preparations had to be determined chemically. This has raised several difficult questions of chemical procedure, especially when natural as well as added sugars are present.

(4) *Tea and cocoa.*—Attempts were made in 1777 to stop the adulteration of tea with foreign and exhausted leaves and other matter, but it was not until 1875 that the Sale of Food and Drugs Act placed on the Revenue authorities the responsibility for examining tea on importation. This is done on an extended scale by the application of chemical, microscopic and practical tests. There has been, however, no imposition of standards in the United Kingdom, as is the case in Canada and the United States.

The duty, and the drawback on the duty, on cocoa preparations has introduced chemical problems into the system of Revenue control, some of them of considerable difficulty, as, for example, those connected with the use of substitutes for the natural cocoa fat.

(5) *Dyestuffs, under the Dyestuffs Import Regulation Act,* 1920.—The importation of dyestuffs under this Act is controlled by a Dyestuffs Advisory Licensing Committee, on which distinguished chemists represent the science.

Importation of synthetic dyestuffs and intermediates is prohibited except under licence, and although the individual substances leave little

room for doubt, more difficult questions come before the Government Laboratory in the case of substances containing a coloured ingredient.

(6) *Substances taken under Safeguarding of Industries Act*, 1921.—Part I of this Act imposes an *ad valorem* duty on the products of certain "Key" industries, of which the fine-chemical manufacturing trade is one. After the Act had passed into law, the Government Laboratory became concerned with the chemical aspect of that section which has gained notoriety through legal inquiries involving the precise significance of chemical and technical terms. But apart from such matters, many difficult chemical problems have arisen in determining the composition of the great variety of chemical substances imported. Thus it has proved a task of some magnitude to deal with about 8000 subjects per annum, when their examination may include the quantitative determination of the ingredients of materials such as synthetic perfumes, photographic developers, medicines, colloidal preparations, alkaloids, etc. The grade of a specified material has also frequently to be assessed, and this involves a special knowledge of its manufacture and use.

The effect of the war was generally to increase the amount of existing duties and to impose fresh ones. The former condition led to increased vigilance in the chemical control on account of the introduction of substitutes to replace the dutiable substances; the latter were imposed as a post-war condition and are described above. In connexion with the war-time prohibition of exports, not only of munitions but practically of all useful commodities, the services of the Government Laboratory were required to decide as to the nature of about 20,000 substances, including cases in which the prohibited goods were skilfully disguised.

For all matters involving chemical advice the Board of Customs and Excise applies to the Department of the Government Chemist, who maintains on his staff for this section of the work a sufficient number of chemists and assistants to make the necessary investigations and deal with the chemical points at issue, as well as to carry out the necessary practical work, both in London and at several of the ports. This aspect of the work of the Government Laboratory involves a knowledge of Revenue law and precedent as well as an intimate acquaintance with a large range of chemical manufacture.

The importance of chemical control in safeguarding the Revenue is obvious. With increase in the number of subjects brought under supervision, the greater refinements and accuracy demanded, the investigation of new processes, and the amount of chemical work, the number of chemists is rapidly increasing.

(*To be continued*)

As Prof. H. Kamerlingh-Onnes, of Leiden, has requested to be relieved of his professional duties, his place will be taken by Prof. W. J. de Maas.

FORTHCOMING EVENTS

Aug. 9. NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS. Annual General Meeting, to be held in the Lecture Theatre of the Institute, Newcastle-on-Tyne, at 2 p.m.

Sept. 4 and 5. IRON AND STEEL INSTITUTE, Autumn Meeting at British Empire Exhibition, at 10.30 a.m. each day. (1) "Changes of Volume of Steels During Heat Treatment," by L. Aitchison and G. R. Woodvine. (2) "Investigations on the Herbert Pendulum Hardness Tester," by C. Benedicks and V. Christiansen. (3) "Effect of Changes in Total Carbon and in the Condition of Carbides on the Specific Resistance and on some Magnetic Properties of Steel," by E. D. Campbell and G. W. Whitney. (4) "Pickling: The Action of Acid on Iron and Steel, and the Diffusion of Hydrogen Through the Metal," by C. A. Edwards. (5) "Examination of Iron from Konarak," by J. N. Friend and W. E. Thorneycroft. (6) "On the Nature of High-Speed Steel," by M. A. Grossman and E. C. Bain. (7) "Improvements in the Brinell Test on Hardened Steel, including a New Method for Producing Hard Steel Balls," by A. Hultgren. (8) "Present Position of the Theories of the Hardening of Steel," by W. Rosenhain. (9) "Effect of Free Surfaces on the Plastic Deformation of Certain Metals," by F. C. Thompson and W. E. W. Millington.

Sept. 8 to 11. INSTITUTE OF METALS. Annual Autumn Meeting, to be opened at the Institution of Mechanical Engineers, when W. M. Corse, S.B., will deliver the third annual Autumn Lecture. On September 9 the morning will be devoted to reading and discussion of papers, followed by luncheon at the Connaught Rooms, Kingsway, the afternoon to be spent at Wembley.

The following papers will be read:—"A Method for Measuring Internal Stress in Brass Tubes," by R. J. Anderson and E. G. Fahlman; "The Application of the Ideal Solubility Curve to the Interpretation of Equilibrium Diagrams in Metal Systems," by D. H. Andrews and Prof. J. Johnston; "Seventh Report of the Corrosion Research Committee of the Institute of Metals," by G. D. Bengough and R. May; "Comparative Results on Copper-Silicon-Aluminium and Other Aluminium Alloys as Obtained on Separately Cast Specimens and Specimens cut from a Crankcase Casting," by E. H. Dix and A. J. Lyon; "The Determination of Sodium in Aluminium," by D. M. Fairlie and G. B. Brook; "The Extrusion of Brass Rod by the Inverted Process," by R. Genders; "Investigation of the Effects of Impurities on Copper. Part II—The Effect of Iron on Copper," by D. Hanson and Grace W. Ford; "The Relationship Between Tensile Strength, Temperature and Cold-Work in Some Pure Metals and Single Solid Solutions," by D. H. Ingall; "On the Effect of Progressive Cold-Rolling on the Brinell Hardness of Copper," by H. Moore; "Experiments on the Working of Nickel for Coinage," by Sir T. K. Rose and J. H. Watson; "Some Experiments on the Effect of Casting Temperature and Heat-Treatment on the Physical Properties of a High-Tin Bronze," by F. W. Rowe; "Some Experiments on the Influence of Casting Temperature and Mass on the Physical Properties of Admiralty Gun-Metal," by F. W. Rowe; "Studies in the Aluminium-Zinc System," by T. Tanabe; "Metal Spraying and Sprayed Metal," by T. H. Turner and W. E. Ballard.

BRITISH ASSOCIATION OF CHEMISTS

The annual meeting of the Manchester Section was held at the Albion Hotel, Dr. J. L. Hankey presiding. In his Annual Address the chairman said that whilst many societies had lost members, the Manchester Section, like the Association in general, could record an increase. The steady influx of new members, especially under the " A " qualification, was most satisfactory, and indicated that the Association filled a purpose which was not served by other existing chemical organisations. The Unemployment Benefit Fund, which was a determining factor in this satisfactory position, appeared to be on sound lines. Benefits had been paid to 26 members, 7 of whom were at present in receipt of benefit. The scheme was founded on an obligatory basis, and it would not be possible to change this to a voluntary basis without involving a large increase in the limit rate of contribution. Dr. Hankey appealed for full support for the Fund from those already in assured positions, and expressed his belief that the Fund was the outward expression of a sentiment of solidarity among chemists which alone could raise the status of the profession. The desirability was emphasised of establishing some working arrangement with the Institute of Chemistry. The Conference held by the Institute at Liverpool last October had evidenced the progress of the view that both organisations were necessary and that they mutually supplemented one another. Negotiations with the National Union of Scientific Workers had led to the agreement to issue a joint Journal which would shortly appear. In conclusion Dr. Hankey appealed for support for the Journal.

Dr. H. Levinstein expressed his agreement with the views expressed by the Chairman, particularly with regard to the Unemployment Benefit Fund, and their relationship with the Institute of Chemistry. There was no doubt that the B.A.C., had made real progress in the last six months, and quite a remarkable change had been brought about in the opinion of the profession in general. Before the Labour Government came into power no deputation from the B.A.C. would have been received by the President of the Board of Trade as the Deputation regarding the Dyestuffs Agreement was received by Mr. Webb. The B.A.C. in this and in other ways was receiving at last its due recognition. Nevertheless rapprochement with the Institute should be one of the main objects, and the B.A.C. should explore all possible avenues of co-operation. Co-operation was one of the great needs of the chemical profession, and its pertinence was enforced by the financial stringency in which the Chemical Society and the Society of Chemical Industry found themselves. As far as possible, all overlapping or duplicating of work, whether in publication or meetings, should be avoided. He thought it not impossible that in the future through central organisation some arrangement for the compounding of subscriptions should be put into operation.

Mr. E. F. Morris, and subsequently Mr. W. E. Kay, explained the motives which had led the Council to receive a deputation from the Society of Technical Engineers and other Engineers' Associations (which were related to the Institutes of Civil and Mechanical Engineering in much the same way as the B.A.C. is related to the Institute of Chemistry) on the subject of the proposed National Council of Staff Technicians. The Council, however, felt that the interests of the Association at present would be best served by concentrating on organisation among chemists themselves, a view endorsed by several other speakers.

Mr. R. Brightman suggested that co-operation with the Institute of Chemistry and with the Society of Chemical Industry might well begin along informal lines. Something might be done if the various committees got into touch at informal meetings, and it should be possible to organise at least one joint meeting during the winter session of the Institute of Chemistry, the Society of Chemical Industry and the B.A.C., in districts where local associations had been formed. Ultimately a joint programme might be arranged for the session open to all members irrespective of what organisations they might be members. In regard to publications, a lead was already being given by the Chemical Society and the Society of Chemical Industry in regard to abstracts of chemical papers. He hoped that this lead would be followed. It should prove possible at any rate to issue in one journal the proceedings of the Chemical Society, the Society of Chemical Industry, the Institute of Chemistry and the B.A.C., instead of scattering them in four volumes as at present. Perhaps the Federal Council would ultimately explore such possibilities of co-operation and economy.

At the election of officers and Committee Mr. C. W. Carpenter was elected chairman, Mr. E. A. Marchment, Hon. Treasurer, and Mr. G. E. Yarrow was re-elected Hon. Secretary. The meeting concluded with votes of thanks to the retiring officers.

SACCHARINE INDUSTRY IN GERMANY

Saccharine was introduced into Germany about forty years ago, when a number of German chemical concerns took up its manufacture and the product became an important article in commerce. The competition thus introduced so threatened the sugar and sugar-beet industry of the country, however, that the Government passed the Saccharine Law. This limited the sale of saccharine to the sick, under certain exceptional circumstances, and confined its manufacture to one company, and the five other German chemical concerns then manufacturing it were forced to cease production. This legislation resulted in considerable stocks being smuggled into Germany from Holland and Switzerland. During the acute sugar shortage experienced through the war the law was repealed in 1916, when the Government allocated its further production to another firm. The demand increasing, the saccharine was rationed until 1920, and since then the trade in this commodity has been free, and it is now widely used both by households and industries. This action of the Government arose from the necessity of exporting considerable sugar in exchange for grain. It is calculated that for one pound of sugar Germany receives five pounds of grain.—(*U.S. Comm. Rep.*, *May* 26, 1924.)

CORRESPONDENCE

A POINT OF ORDER

Sir,—There is no difficulty in representing by means of conventional symbols the fact that one atom has transferred an electron to each of two other atoms. This can be shown by comparing the polar formula of the nitro-group I with that of the carboxyl-group II.

Each formula shows two negatively-charged oxygens; but these have taken their extra electrons in one case from an atom of carbon and an atom of hydrogen, whilst in the other case both electrons have been taken from the same atom of nitrogen. The positive and negative charges are, however, completely balanced, so that each group is a neutral radical (although strongly polarised) and not an ion.

These conventional formulæ will be found to be in harmony with the complete electronic formulæ, since the atoms of nitrogen and of carbon are each credited with a *sextet* of L-electrons, precisely as in the nitrate and carbonate ions, the three-fold symmetry of which is reproduced in the crystals of sodium nitrate and of calcite. It is, however, much more risky to assign a double positive charge to carbon than to nitrogen, since this would usually imply (*e.g.*, in acetylene, if formulated as $\mathrm{H}\overset{++}{\mathrm{C}}\!-\!\overset{--}{\mathrm{C}}\mathrm{H}$) a reduction in the number of L-electrons to four.

The application of these electronic formulæ to compounds of the type of vinyl ethyl ether introduces an additional problem. I presume that this compound acts primarily as an olefine, and that the main (but not necessarily the only) product of activation would be represented by the polar formula $\overset{-}{\mathrm{C}}\mathrm{H}\cdot\overset{+}{\mathrm{C}}\mathrm{H}\cdot\mathrm{O}\cdot\mathrm{C_2H_5}$. In such a case the oxygen appears to determine the direction in which the ionisation of the vinyl-group will preferentially occur; but it is difficult to picture the oxygen in an ether as itself becoming ionised, unless perhaps in an oxonium salt, *e.g.*, in a hydriodide formed as an intermediate product prior to splitting off ethyl iodide. Some separate symbol is therefore evidently needed to express the influence of groups which do not themselves react, but are none the less able to influence the way in which the more reactive groups in the molecule will react.

I am glad to be able to confirm by optical evidence the view that "the benzene ring may functionate as a resonator rather than as a true key polarising group," since this phrase expresses exactly the influence of the aromatic ring in benzylidene-camphor on the absorption spectrum of the parent ketone. In this case Miss H. S. French has shown that the "resonance" of the conjugated system increases the intensity of the selective absorption of the carbonyl group 560 times, but without producing the slightest alteration in the characteristic frequency of the band. The second carbonyl-group in camphorquinone, on the other hand, refuses to accept this passive role, and shifts the selective absorption from the ultra-violet into the visible region, although the intensity of the absorption is not changed. The relevant curves and data are contained in a paper of which an abstract has already appeared in this *Journal* (this vol., p. 641).—I am, Sir, etc.,

T. M. Lowry

THE USE OF ALUMINIUM UTENSILS

Sir,—Allow me through the medium of your columns to thank Mr. Jeromo Alexander for his suggestion of a possible danger in the use of "aluminium" for pots and pans in which food has to be cooked. If aluminium is alloyed with zinc or copper, is it at all likely that these latter metals would dissolve in the presence of metallic aluminium? I should scarcely think so. If anything was dissolved it would be aluminium. Although this is more than mere surmise, the confinement to my chair prevents me from making experiments to prove it. Although aluminium is not classed with the poisonous metals, yet one does not know what its effects may be when taken day after day in some condition of solution or colloid. The detection of small quantities of aluminium, when mixed with soup, jam, or other foods, might be no easy matter—not like the detection of lead or copper. In the old days of adulteration of bread with alum, the colour test with logwood was generally used. Alizarine was subsequently used by me as a distinctive test for alumina (*J.S.C.I.*, 1885, 310), and possibly a method somewhat as follows might serve the purpose:—Decolorise with chlorine—destroy excess—exactly neutralise, or leave very faintly acid—add a little sodium acetate and a drop of acetic acid—boil with a very little alizarine, say one drop of a 1 per cent. mixture with water. The presence of aluminium would probably be indicated by a pink or red coloration. Not being able to make experiments myself I thought that these suggestions might be of some use to those who are interested in the matter.—I am, Sir, etc.,

Joseph Barnes

PERSONAL AND OTHER ITEMS

Dr. J. T. Conroy and Mr. F. W. Bain have been appointed as additional directors to the board of the United Alkali Co., Ltd.

Lord Bearsted has given £10,000 to the University of Sheffield for the encouragement of study and research in the department of metallurgy. As Lord Mayor of London Lord Bearsted laid the foundation-stone of the university buildings 21 years ago.

The title of Reader in Physical Chemistry in the University of London has been conferred on Mr. W. E. Garner, M.Sc., in respect of his post at University College.

Dr. Shiro Tashiro, associate professor of biochemistry in the University of Cincinnati, has been awarded the Gakushûn prize by the Imperial Academy of

Arts and Science of Japan for his work "in proving that the nervous impulse is a chemical reaction and not primarily a physical reaction."

Prof. Julius Wagner, who died recently at the age of sixty-seven, had held a professorship in the University of Leipzig since 1901. His work lay mostly in the domain of analytical chemistry, and he had published books on mass analysis, tables of chemical constants and related subjects.

We greatly regret to announce the death of Sir George Beilby, F.R.S., who was president, during the year 1898-99, of the Society of Chemical Industry. An obituary will appear in a later issue.

Information Bureaux and Special Libraries

A Conference will be held at High Leigh, Hoddesdon, Herts, during the week-end September 5-8, to which are invited all those who need to utilise information systematically, or who are interested in the conduct or operation of information bureaux, intelligence services and special libraries. The programme will include papers and discussions on the functions, future developments, and the methods and equipment of intelligence bureaux, and on their relations with other institutions, including national and public libraries. It is hoped to obtain representatives of such varied fields of activity as Government and municipal departments, technical and research institutions, industrial concerns, financial houses, insurance offices, newspapers and civic and social organisations, all of which have a common interest in the collection, treatment and dissemination of facts and information relevant to their particular activities. Further information may be obtained from Mr. A. F. Ridley, Athenæum Chambers, 71, Temple Row, Birmingham.

Gift to Leeds University

The Council of the University of Leeds, at its meeting on July 16, received with much pleasure an announcement of the gift by Mr. Alfred Lund, J.P., of Pudsey, of a sum of £5000 for the foundation of scholarships for students of the Clothworkers' Departments, and the following resolution was passed:—

> That the Council records its deep sense of gratitude to Mr. Alfred Lund, J.P., for his liberal gift of £5000 for the foundation of scholarships for students of the Clothworkers' Departments. This practical evidence of interest and confidence in the work of the University is a source of great encouragement to all its members, and the Council is gratified to think that Mr. Lund's generosity will be the means of enabling promising students of the Clothworkers' Departments to undertake study and research which will lead to the further advancement of so important an industry.

Iron Ore in Tasmania

A conservative estimate of the iron ore deposits in Tasmania by Messrs. W. H. Twelvetrees and A. M. Reid, government geologists, gives the amount of 42,710,000 tons. The following are the localities in which the ore deposits occur:—Blyth river, 17,000,000 t.; Dial Range and Penguin, 700,000; Long Plains (Rio Tinto), 20,000,000; Zeehan district, 3,700,000; and Beaconsfield and Anderson's Creek, 1,300,000 t. The Rio Tinto deposits are estimated to have an average grade of 65 per cent. iron. The Zeehan district deposits show an analysis of over 70 per cent. iron. The Blyth river deposits run from 44 per cent. up to 69 per cent. iron. Iron-ore deposits occur in several other districts, but they are insufficiently developed and investigated to enable an ore reserve to be expressed in figures.

Metallurgy in Luxemburg in April

The metallurgical output in Luxemburg in April 1924 was 185,625 tons of cast iron, and 156,868 t. of steel, compared with 165,312 t. and 150,952 t. respectively, in the preceding months. By far the bigger proportion was produced by the Thomas process.

The Italian Glycerin Trade

Since the war the Italian foreign trade in glycerin has not been important. Domestic production suffices for local needs, and a small quantity of the crude is exported to London, Hamburg and Antwerp. Some purchases through London are for shipment to New York, and occasionally direct sales to importers in the United States are effected. In 1922, the production of crude glycerin amounted to 13,800 quintals (1 quintal=220·46 lb.), compared with 9100 q. in 1921, 8400 q. in 1920, 7220 q. in 1919, and 20,450 q. in 1918. The output of refined glycerin totalled 6070 quintals in 1922, against 5400 in 1921, 10,400 in 1920, 12,700 in 1919 and 22,750 in 1918. Shipments of crude glycerin are usually made in iron cylinders holding about 400 litres, weighing approximately 1100 lb. The buyer frequently furnishes the containers. For domestic trade, refined glycerin is sold in glass containers holding approximately 100 lb. The following table shows the Italian foreign trade in glycerin during 1923, and also for 1913, and the years 1919 to 1922 inclusive:—

	Imported Quintals	Exported Quintals
1913	7009	12,588
1919	22,908	17,448
1920	76	29,715
1921	3572	5594
1922	4178	2802
1923	760	2676

Of the amount exported in 1923, 97 per cent. was crude, and of the imports 60 per cent. was refined.—(*U.S. Com. Rept.*, *June* 9, 1924.)

Rapid Drying of Gelatin

One of the difficulties in the manufacture of glue and gelatin is the lengthy and costly process of drying. According to Dr. H. Stadlinger (*Chem. Z.*, July 1), this difficulty is obviated by forcing the liquid extract through fine nozzles into a liquid or gaseous medium, when the rotatory motion imparted causes the formation of small drops which at a suitable temperature can be dried within one minute, without any injury to the gelatin. It is claimed that, with equal weights, the drops will adsorb 110 times their weight of water in 30 minutes, whereas the sheet product requires 24 hours. Work is proceeding in the Scheidemandel laboratory on the production of various grades of glue and gelatin.

Asbestos in Canada

Sales of asbestos by the mines in Canada for 1923, in quantity exceeded that of the previous year, being 231,482 tons valued at $7,522,506 compared with 163,706 t. valued at $5,552,723 in 1922. Total asbestos rock mined was 3,768,542 t., and the mill recovery of marketable asbestos 237,000 t., or approximately 7·3 per cent.

OBITUARY

W. R. EARP

The death of William Richard Earp marks the end of a career remarkable for persistence of effort under difficulties. Born in 1847, at Hope, Dovedale, Earp first gained opportunity for self-instruction as assistant librarian to the Mechanics' Institute, Hanley. Whilst still young, he became an assistant surveyor in the Talk o' the Hill Colliery, and in 1868 he entered the chemical trade in London. In 1872 he set up a small firm to manufacture fertilisers in Staffordshire, and four years later he left to establish the Ellesmere Chemical Works in Runcorn, where he made pure chemicals for laboratory use, and also distilled naphtha and refined lead and other metallic residues. Coming into contact with the tanning industry, the success of a patent depilator and a patent antiseptic induced him to take over a tannery at Preston Brook, and to manufacture tanners' chemicals at Ellesmere. A venture into the borax industry in 1895 proved disastrous, as he refused a fair offer to join Borax Consolidated (formed owing to competition in the trade), and he was cut off from raw materials, whilst an investment in a bogus borate mine in Argentina entailed heavy losses. Ill-health and the collapse of the main building at his works made financial disaster inevitable. Mr. Earp was not daunted, but started again, with continuous success, as a manufacturer of tanners' chemicals, specialising in sulphonated oils. He died suddenly on July 25, in his chair during sleep, an active worker to the last. He was an original member of the Society of Chemical Industry.

PARLIAMENTARY NEWS

Subsidy to Beet-Sugar Production

Speaking in the Committee of Supply on the estimates for the Ministry of Labour, Mr. Snowden said that the Government had accepted the principle of Exchequer assistance for the sugar beet industry. Excise duty of 9s. 9d. would be put upon beet sugar manufactured in this country, but they would have a subsidy of 19s. 6d. per cwt. State assistance for ten years was needed to enable the industry to find its feet. The subsidy might be reduced to 13s. in four years, but legislation would be necessary. The subsidy would enable six new factories to be started almost at once, employing more labour. [The Government proposal will give the home beet-sugar industry the advantage of 21s. 5d. over foreign imported sugar, instead of 11s. 8d. as at present.]

REVIEW

THE SPECIFIC HEATS OF GASES. By J. R. PARTINGTON and W. G. SHILLING. Pp. 252. London: Ernest Benn, Ltd., 1924. Price 30s.

In consideration of the importance of the question of the specific heats of gases, it is rather singular that a coherent account of the subject should not hitherto have been presented in book form. On the one hand, problems involving heat capacities are amongst those with which the technologist in a great variety of industrial processes is continually concerned, whilst on the other it is apparent that exact measurements of the specific tests of gases over wide ranges of temperature and pressure afford material of fundamental importance for the investigation of many theoretical problems. In the circumstances, it may be taken for granted that the present work will appeal to a wide circle.

The subject matter is divided into six chapters. In the first are discussed the more important equations of state, of which some fifty-six are reproduced. The second is concerned with the methods of determining specific heats, and the third with the influence of temperature. Chapter IV deals with the influence of pressure and with a number of important general relations such as Kirchhoff's equation, Nernst's theory and the so-called reaction isochore. In tables which form a supplement to these four chapters, the authors have collected all the available specific heat data for normal temperatures and pressures. From these, a critical selection has been made, and further tables give the true and mean heat capacities of the industrially important gases over the range of 0°–2000° C. In Chapter V the application of specific data to problems connected with internal combustion engines, furnaces, gas producers and refrigerators is considered, whilst the final chapter is devoted to a brief consideration of the theoretical aspect of the subject.

The authors state explicitly that the book is not intended for the elementary student, but is addressed to the expert. It should not be inferred from this that the work is merely theoretical, or that any advanced knowledge of mathematics or mathematical physics is required before the reader may hope to appreciate its merits. On the contrary, it is essentially concerned with the experimental aspect of the subject.

It represents a valuable critical survey of the entire field, affords a clear picture of what has been accomplished in this province of research, and indicates to what extent available data require to be supplemented in the interests both of theory and practice.

As a book of reference it will be found most useful, and the authors have undoubtedly succeeded in their endeavour to present the basic facts without attempting to provide for all the possibilities of their application.

The bibliography which the authors have compiled should also be of great value, not only to the works chemist, but to those who contemplate research work involving the measurement of heat capacities.

H. M. DAWSON

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech.	£23 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	£45 per ton.
Powder	£47 per ton.
Acid Hydrochloric	3s. 0d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers' works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Methylated Spirit 64 o.p.—	
Industrial	3s. 1d.—3s. 5d. per gallon, according to quantity.
Mineralised	4s. 2d.—4s. 6d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	5¾d. per lb.
Potass. Chlorate	3d.—4d. per lb
Salammoniac	£32 per ton d/d.
Salt Cake	£3 10s. per ton d/d.
Soda Caustic, solid	Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals	£5 5s—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton, carr. paid.
Sod. Bichromate	4½d. per lb.
Sod. Bisulphite Powder 60/62%	£18—£19 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Sulphide conc. 60/65	About £14 10s. per ton d/d.
Sod. Sulphide cryst.	£9 per ton d/d.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	5¾d.—1s. 4d. per lb., according to quality.
Crimson	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 1d. per lb.
Barytes	£3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide	3s. 9d. per lb.
Carbon Bisulphide	£24—£26 per ton according to quantity.
Carbon Black	7d. per lb. ex wharf. Dearer.
Carbon Tetrachloride	£56 per ton, drums free.
Chromium Oxide, green	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	45s per cwt., barrels free.
Lead Hyposulphite	7½d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£15 10s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Sulphur Chloride	3d. per lb., carboys extra.
Thiocarbanilide	2s. 6d. per lb.
Vermilion, pale or deep	4s. 10d. per lb.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£14 10s. per ton d/d. Demand active.
Grey	£19—£20 per ton. Fair demand.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 per ton, according to grade and locality. Demand below normal.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. „ „ 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 7d. per gall. Unrefined.
Wood Naphtha—	
Miscible	5s. per gall. 60% O.P. Market dull.
Solvent	5s. 6d. per gall. 40% O.P. Fairly good demand.
Wood Tar	£5 per ton.
Brown Sugar of Lead	£46 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	6½d.—6¾d. per lb. Quiet.
Crude 60's	1s. 9d.—1s. 11d. per gall., according to district. Still quiet.
Acid Cresylic, 97/99	2s 1d.—2s. 2d. per gall. Demand still good. Market firm.
Pale 95%	1s. 10d.—1s. 11d. per gall. Steady demand.
Dark	1s. 10d.—1s. 11d. per gall. Steady business.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	8½d.—9½d. per gall. Quiet.
Unstrained	7½d.—8½d. per gall.
Benzole—	
Crude 65's	10½d.—1s. per gall. ex works in tank wagons.
Standard Motor	1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure	1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.
Toluole—90%	1s. 5½d. per gall.
Pure	1s. 8d.—2s. per gall.
Xylol coml.	2s. 3d. per gall.
Pure	3s. 3d. per gall.

Creosote—

Cresylic 20/24%	.. 9d.—9½d. per gall. Few inquiries.
Middle Oil .. / Heavy Oil .. / Standard Specification	5½d.—6d. per gall in Lancashire; 6d.—7d. per gall. in Yorkshire.

Naphtha—

Solvent 90/160	.. 1s. 1d.—1s. 4d. per gall. according to district. Quiet.
Solvent 90/100	.. 1s. 1d.—1s. 4d. Quiet.

Naphthalene Crude—

Drained Creosote Salts	£4—£6 10s. Quiet.
Whizzed or hot pressed	£9 per ton. Little business.

Naphthalene—

Crystals and Flaked	.. £13—£16 per ton in Yorkshire and London respectively. More inquiries.
Pitch, medium soft	.. 55s.—60s. per ton f.a.s. for next season. Frequent inquiries.
Pyridine—90/160	.. 19s. per gall. Market less firm.
Heavy	.. 12s.—12s. 6d. Little business.

INTERMEDIATES AND DYES

There has been a fair demand for dyestuffs during the past week. Prices remain constant. A number of intermediate products have been reduced in price.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	.. 1s. 7d. per lb.
Acid H.	.. 4s. per lb 100% basis d/d.
Acid Naphthionic	.. 2s. 4d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech.	.. 1s. 1d. per lb. Improved demand.
Acid Sulphanilic	.. 9½d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	.. 1s. per lb. d/d.
Aniline Oil	.. 7¾d.—8½d. per lb. naked at works.
Aniline Salts	.. 7¾d.—9d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	.. 4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95%	.. 1s. 1d. per lb.
p-Chlorphenol	.. 4s. 3d. per lb. d/d.
p-Chloraniline	.. 3s. per lb. 100% basis.
o-Cresol 19/31° C.	.. 4½d. per lb. Demand steady.
m-Cresol 98/100%	.. 2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	.. 2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloranilino	.. 2s. 3d.—2s. 11d. per lb.
Dichloraniline S. Acid	.. 2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	.. £85 per ton.
Diethylaniline	.. 4s 7d. per lb. d/d., packages extra, returnable.
Dimethylaniline	.. 2s. 4d. per lb. d/d. Drums extra.
Dinitrobenzene	.. 9d. per lb. naked at works.
Dinitrochlorbenzol	.. £84 10s. per ton d/d.
Dinitrotoluene—48/50° C.	8d.—9d. per lb. naked at works.
66/68° C.	1s. 2d. per lb. naked at works.
Diphenylamine	.. 3s. per lb. d/d
Monochlorbenzol	.. £63 per ton.
β Naphthol	.. 1s. 1d. per lb. d/d.
α-Naphthylamine	.. 1s. 4½d. per lb. d/d.
β-Naphthylamine	.. 4s. per lb. d/d.
m-Nitraniline	.. 5s. 3d. per lb. d/d.
p-Nitraniline	.. 2s. 3½d. per lb. d/d.
Nitrobenzene	.. 5¼d.—5½d. per lb. naked at works
o-Nitrochlorbenzol	.. 2s. per lb. 100% basis d/d.
Nitronaphthalene	.. 11d. per lb. d/d.
p-Nitrophenol	.. 1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	.. 4s. per lb. d/d.
p-Phenylene Diamine	.. 10s. 3d. per lb. 100% basis d/d.
R. Salt	.. 2s. 6d. per lb. 100% basis d/d.
Sodium Naphthionate	.. 2s. 3d. per lb. 100% basis d/d.
o-Toluidine	.. 8½d. per lb.
p-Toluidine	.. 3s. 6d. per lb. naked at works.
m-Toluylene Diamine	.. 4s. 3d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P	.. £45 per ton.
Acid, Acetyl Salicylic	.. 3s. 2d.—3s. 5d. per lb., according to quantity. Good demand. Price firm.
Acid, Benzoic B.P.	.. 3s. 6d. per lb. Larger supplies available.
Acid Boric B.P.	.. Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	.. 19s.—21s. per lb.
Acid, Citric	.. 1s. 5¾d. per lb., less 5% for ton lots. Business sub-normal.
Acid, Gallic	.. 3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst.	.. 7s. per lb. for 1 cwt. lots. Market firm; increasing demand.
Acid, Salicylic	.. 1s. 6d.—2s. per lb. Weak market.
Acid, Tannic B.P.	.. 3s. per lb. Market quiet.
Acid, Tartaric	.. 1s. 1¼d. per lb. less 5%.
Amidol	.. 9s. per lb. d/d.
Acetanilide	.. 2s. 1d.—2s. 3d. per lb. for quantity. Demand slow.
Amidopyrin	.. 13s. 3d. per lb. Neglected. Stocks low.
Ammon. Benzoate	.. 3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	.. 12s. 6d. per oz. for English make.
Barbitone	.. 15s.—15s. 6d. per lb. Quiet market.
Benzonaphthol	.. 5s. 3d. per lb. Small inquiry.
Bismuth Salts	.. A steady market. Prices according to quantity:
Bismuth Carbonate	.. 12s. 9d.—14s. 9d. per lb.
,, Citrate	.. 11s. 4d.—13s. 4d. ,,
,, Salicylate	.. 10s. 2d.—12s. 2d. ,,
,, Subnitrate	.. 10s. 9d.—12s. 9d. ,,
Borax B.P.	.. Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides	.. Unsettled. Spot supplies short. Raw materials dearer. Market advancing. Average spot values:— Ammonium .. 1s. per lb. Potassium .. 10d. per lb. Sodium .. 11d. per lb.
Calcium Lactate	.. Demand active. Good English make can be had from 1s. 7d. to 2s. 6d. per lb.
Chloral Hydrate	.. 4s.—4s. 3d. per lb. Very firm and scarce.
Chloroform	.. 2s. per lb. for cwt. lots. Very steady
Creosote Carbonate	.. 6s. 6d. per lb. Little demand.
Formaldehyde	.. £54 per ton, *ex* works. English make in casks. About 8s. per cwt. extra for carboys.
Glycerophosphates—	Fair business passing.
Calcium, soluble and citrate free	.. 7s. per lb.
Iron	.. 8s. 9d. per lb.
Magnesium	.. 9s. per lb.
Potassium, 50%	.. 3s. 6d. per lb.
Sodium, 50%	.. 2s. 6d. ,,
Guaiacol Carbonate	.. 10s. 6d.—11s. 3d. per lb.
Hexamine	.. 3s. 6d. per lb. for English make. Market steady.

Homatropine Hydrobromide	30s. per oz.
Hydrastine hydrochlor	English make offered at 120s. per oz.
Hypophosphites—	
Calcium	3s. 6d. per lb., for 28-lb. lots.
Potassium	4s. 1d. per lb.
Sodium	4s. ,,
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 5d. per lb., according to quantity.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£75 per ton, less 2½%.
Heavy Commercial	£26 per ton, less 2½%.
Heavy Pure	1s. 6d.—2s. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	50s. per lb. Market better.
Synthetic	26s.—35s. per lb., according to quantity. English make. Strong demand.
Mercurials	Market flat.
Red oxide	5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	3s. 6d.—3s. 7d. ,,
White precip.	4s. 7d.—4s. 8d. ,,
Calomel	3s. 11d.—4s. ,,
Methyl Salicylate	1s. 10d.—2s. per lb. Keen competition.
Methyl Sulphonal	26s. per lb.
Metol	11s. per lb. British make.
Paraformaldehyde	2s. 10½d.—3s. per lb. Not very active.
Paraldehyde	1s. 5d.—1s. 6d per lb. in free bottles and cases.
Phenacetin	6s.—6s. 3d. per lb. Price and demand steady.
Phenazone	7s. 6d. per lb. A shade firmer. Forward prices higher.
Phenolphthalein	6s 6d. per lb. Ample supplies.
Potass. Bitartrate—	
99/100% (Cream of Tartar)	88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate	1s. 10d.—2s. 2d. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues heavy.
Potass. Metabisulphite	7½d. per lb., 1-cwt. kegs included.
Potass. Permanganate	6½d. per lb. Keen competition keeps price low.
Quinine Sulphate	2s. 3d. per oz., in 100 oz. tins. Very heavy demand.
Resorcin	5s. 6d.—5s. 9d. per lb. Firmer. Scarce.
Saccharin	63s. per lb., in 50-lb. lots.
Salol	3s. 6d.—3s. 11d. per lb.
Silver proteinate	9s. 6d. per lb.
Sod. Benzoate, B.P.	2s. 6d. per lb. Ample supplies. B.P. quality available.
Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity.
Sod. Hyposulphite—	
Photographic	£13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	75s.—82s. 6d. per cwt., according to quantity. Steady market, good demand.
Sod. Salicylate	Market more active. Powder 2s. 2d.—2s. 4d. per lb. Crystal at 2s. 4d.—2s. 6d. per lb. Flake 2s. 9d. per lb.
Sod. Sulphide—	
Pure recryst.	10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Sulphonal	15s. 6d. per lb. Easier.
Thymol	19s. per lb. Very scarce indeed. Still rising. Forward quotations 22s. per lb.

PERFUMERY CHEMICALS

Acetophenone	12s. 6d. per lb.
Aubepine	15s. 3d. ,,
Amyl Acetate	2s. 9d. ,,
Amyl Butyrate	6s. 9d. ,,
Amyl Salicylate	3s. 3d. ,,
Anethol (M.P. 21/22° C.)	4s. 6d. ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 10½d. ,,
Benzyl Alcohol free from Chlorine	2s. 10½d. ,,
Benzaldehyde free from Chlorine	3s. 6d. ,,
Benzyl Benzoate	3s. 6d. ,,
Cinnamic Aldehyde Natural	16s. ,,
Coumarin	20s. ,,
Citronellol	17s. ,,
Citral	9s.—9s. 6d. Price reduction due to selling competition.
Ethyl Cinnamate	13s. 6d. ,,
Ethyl Phthalate	3s. 3d. ,,
Eugenol	11s. ,,
Geraniol (Palmarosa)	35s. ,,
Geraniol	11s.—18s. 6d. per lb.
Heliotropine	7s. 9d. ,,
Iso Eugenol	15s. 9d. ,,
Linalol ex Bois de Rose	26s. ,,
Linalyl Acetate	26s. ,,
Methyl Anthranilate	9s. 6d. ,,
Methyl Benzoate	6s. ,,
Musk Ambrette	45s. ,,
Musk Xylol	14s. ,, Again cheaper
Nerolin	4s. 9d. ,,
Phenyl Ethyl Acetate	15s. ,,
Phenyl Ethyl Alcohol	16s. ,,
Rhodinol	57s. 6d. ,,
Safrol	1s. 10d. ,,
Terpineol	2s. 4d. ,,
Vanillin	26s. per lb.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	15s. 6d. per lb.
Anise Oil	2s. 8d. per lb.
Bergamot Oil	19s. 6d. per lb.
Bourbon Geranium Oil	36s. 6d. ,,
Camphor Oil	75s. per cwt.
Cananga Oil Java	10s. 6d. per lb.
Cinnamon Oil, Leaf	6½d. per oz.
Cassia Oil, 80/85%	8s. 9d. per lb.
Citronella Oil—	
Java 85/90%	5s. 8d. per lb.
Ceylon	3s. 7d. per lb.
Clove Oil	7s. 6d. per lb. Firm.
Eucalyptus Oil 70/75%	2s. 1d. per lb. Price advanced on fair business.

Lavender Oil—	
French 38/40% Esters	30s. per lb. Very fair. Higher price expected owing to bad crops.
Lemon Oil ..	.. 3s. per lb.
Lemongrass Oil	.. 3d. per oz.
Orange Oil, Sweet	.. 13s. per lb.
Otto of Rose Oil—	
Bulgarian ..	.. 37s. 6d. per oz. Production below average.
Anatolian ..	.. 18s. per oz.
Palma Rosa Oil ..	.. 19s. per lb.
Peppermint Oil—	
Wayne County	.. 21s. per lb. Firm spot and forward.
Japanese ..	.. 14s. 3d. per lb.
Petitgrain Oil ..	.. 9s. 3d. per lb.
Sandal Wood Oil—	
Mysore	.. 26s. 6d. per lb.
Australian ..	.. 21s. per lb.

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before Sept. 30th, they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on August 14th.

I.—Applications

Allan (Dodson). Manufacture of emulsions. 17,379. July 21.

Coles. Mixing, drying and calcining. 17,486. July 22.

Ekstrom. Preheaters. 17,694. July 24.

Galloways, Ltd., and Pilling. Apparatus for accumulating heat of exhaust steam 17,458. July 21.

Granton. Mills for mixing, disintegrating, dissolving, or colloidising materials. 17,483. July 22.

Hamilton. Filters. 17,524. July 22.

Huber. Furnace. 17,396. July 21. (U.S., 19.7.23.)

Wellington. Disintegrator machines. 17,740. July 25.

I.—Complete Specifications Accepted

3902 (1923). Bendixen. Emulsification of liquids which will not mix. (219,038.)

9269 (1923). Field. Apparatus for the formation and separation of solids from liquids or gases by heat interchange. (219,062.)

13,002 (1923). A.-G. der Maschinenfabr. Escher, Wyss, et Cie. Refrigerating plants. (199,008.)

16,609 (1923). Lorenzen. System and apparatus for utilising the heat of waste gases for driving turbines. (219,151.)

II.—Applications

Dellwik. Removing liquid from peat, wood, etc. 17,604. July 23.

General Electric Co., Ltd., and Smithells. Manufacture of coated metal filaments. 17,610. July 23.

Jones and Parker. Distillation of coal etc. 17,454. July 21.

Pieters. Continuous furnace for distillation of lignite etc. 17,621. July 23. (Fr., 23.7.23.)

Potts (Zeche M. Stinnes). 17,742. *See* VII.

Sutcliffe. Distillation of carbonaceous substances. 17,640. July 23.

II.—Complete Specifications Accepted

8537 (1923). Holmes, and Gas Light and Coke Co. Preparation of combustible materials. (219,059.)

10,293 (1923). Smith, and Wellman Smith Owen Engineering Corporation, Ltd. Apparatus for use in burning pulverised fuel. (219,076.)

10,348 (1923). Brightmore. Powdered fuel and like burners. (219,078.)

13,561 (1923). Collin and Co. Coke-oven plants. (197,968.)

16,549 (1923). Finley. *See* IX.

16,609 (1923) Lorenzen. *See* I.

31,235 (1923). Uehling. *See* XXIII.

III.—Complete Specification Accepted

10,592 (1923). Coke and Gas Ovens, Ltd. (Stall, Kuhn, and Fritzsche). *See* XIII.

IV.—Applications

Fritzsche and Society of Chemical Industry in Basle. Manufacture of substantive azo-dyestuffs. 17,545. July 22.

Johnson (Badische Anilin und Soda Fabrik). Production of diazo compounds. 17,439. July 21.

Jones, Morton, Morton Sundour Fabrics, Ltd., and Wylam. Dyes and dyeing. 17,807. July 25.

Knecht. Production of diazo and nitroso compounds. 17,862. July 26.

Zeche M. Stinnes. Production of phenols. 17,741. July 25. (Ger., 27.7.23.)

V.—Application

Lindsay (Barbour). Method of disintegrating vegetable and wood fibres etc. 17,642. July 23

V.—Complete Specifications Accepted

13,478 (1923). Kay. Machines for washing wool or for performing like operations. (219,128.)

23,422 (1923). Clavel. Treatment of threads, yarns, and fabrics of or containing acetyl cellulose. (206,818.)

28,155 (1923). Boeken. Process and means for obtaining fibre from the stalks of ramie and other woody plants. (219,226.)

VI.—Applications

Cassella und Co. Ges. Production of effect threads of cotton etc. 17,450. July 21. (Ger., 5.11.23.)

Jones, Morton, Morton Sundour Fabrics, Ltd., and Wylam. 17,807. *See* IV.

Standard Silk Dyeing Co. Washable dyed silk piece goods, and processes of dyeing same. 17,719. July 24. (U.S., 1.12.22.)

VII.—Applications

Meyerhofer. Production of hydrofluosilicic acid. 17,722. July 24. (Ger., 1.10.23.)

Meyerhofer. Production of soluble carbonates or hydroxides from insoluble carbonates, oxides, or hydroxides. 17,723. July 24. (Ger., 2.8.23.)

Potts (Zeche M. Stinnes). Purification of crude ammoniacal liquors. 17,742. July 25.

IX.—Application

Coles. Cement. 17,488. July 22.

IX.—Complete Specification Accepted

16,549 (1923). Finley. Bituminous cement aggregate composition. (219,150.)

X.—Applications

Flodin. Methods for producing metals and metal alloys low in carbon. 17,919. July 26. (Sweden, 27.7.23.)

Hutchins. Electro-deposition of metals. 17,715. July 24.

Soc. l'Air Liquide Soc. Anon. pour l'Etude et l'Exploitation des Procédés G. Claude. Autogenous welding of aluminium, magnesium, and their alloys. 17,841. July 25. (Fr., 1.4.24.)

X.—Complete Specifications Accepted

7846 (1923). Saklatwalla. Manufacture of alloy steel and iron. (196,260.)

8888 (1923). Westwood. Siemens' open-hearth furnaces. (219,061.)

XI.—Applications

Ashcroft. Electric batteries for conserving and utilising energy. 17,440. July 21.

Smith. Electric batteries. 17,678. July 24.

XII.—Application

Brimley, Dickinson, and Nigerian Products, Ltd. Extraction of oil from palm fruit etc. 17,378. July 21.

XIII.—Application

Hocking. Manufacture of red lead. 17,419. July 21. (Hungary, 16.8.23.)

XIII.—Complete Specification Accepted

10,592 (1923). Coke and Gas Ovens, Ltd. (Still, Kuhn, and Fritzsche). Apparatus for use in connexion with the extraction and removal of resin from solution in acid. 219,089.)

XIV.—Complete Specification Accepted

28,898 (1923). Kempter. Apparatus for the washing of india-rubber and the like. (207,189.)

XV.—Complete Specifications Accepted

7750 (1923). Lloyd. Method of hydrolysis in glue and gelatine manufacture. (219,052.)

24,017 (1923). Baxter. Means for agitating washing, liming, or tanning solutions. (205,067.)

XVII.—Complete Specification Accepted

21,565 (1923). Ragg. Clarification and decolorisation process for the manufacture of white sugar. (219,194.)

XVIII.—Complete Specification Accepted

10,008 (1923). Wooldridge. Brewing. (219,068.)

XX.—Application

Busch and Von Wulfing. Manufacture of acid calcium lactate. 17,645. July 23.

XXI.—Applications.

Bannister. Colour photography. 17,596. July 23.

Jelley. Photographic sensitisers. 17,507. July 22.

Melin Machine Co., Ltd. (Schwartz Presse Akt.-Ges.). Photo-chemical lithography. 17,498. July 22.

XXIII.—Complete Specification Accepted

31,235 (1923). Uehling. Apparatus for detecting or estimating and recording combustible constituents in gaseous mixtures. (219,236.)

GENERAL NOTES

Inquiry into British Industry and Commerce

H.M. Government has appointed a Committee to inquire into and report upon the conditions and prospects of British industry and commerce, with special reference to the export trade, and to make recommendations in regard thereto. The Committee is constituted as follows :—Sir Arthur Balfour, K.B.E. (Chairman), Mr. John Baker, Sir W. H. Beveridge, K.C.B., Mr. Henry Boothman, Mr. W. T. Charter, Mr. C. T. Cramp, Mr. Hugh Dalton, Sir Harry Goschen, K.B.E., Mrs. M. A. Hamilton, Mr. F. A. Hargreaves, Sir Norman Hill, Bart., Sir John S. Hindley, Mr. David Landale, Sir W. Clare Lees, O.B.E., Mr. P. J. Pybus, C.B.E., Mr. Arthur Shaw, Sir Allan Smith, K.B.E., and Sir Hubert Llewellyn Smith, G.C.B. The chief points to be discussed are the present position of British overseas trade and its future, the state of British productive capacity and its organisation (labour, capital and management), and the relations between those engaged in production. Communications relating to the Committee should be addressed to the Secretary, Mr. Walter Carter, Board of Trade, Great George Street, London, S.W. 1.

Official Trade Intelligence

The Department of the Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number :—*Australia :* Asphalt and bituminous concrete (139) ; *Chile :* Earthenware and essences (158) ; Textiles (159) ; *China :* Paints (B.X./1052) ; *India, Burma and Ceylon :* Glass paper, emery paper and emery wheels (140) ; *Netherlands :* Leather (146 and 147) ; Ironware (148) *Peru :* Paints (B.X./1088) ; *Poland :* Leather and chemicals (152) ; Leather and tanning materials (153) ; *South Africa :* Centrifugal pumps and motors (258) ; *Sweden :* Chemicals (154).

PUBLICATIONS RECEIVED

The Rubber Conference, Brussels, 1924. Official Report of the International Rubber Conference held in Brussels in April, 1924, together with the papers read and the discussions thereon. Pp. 218. London: Rubber Growers' Association (Inc.), 1924. Price 5s.

Report on the Industries and Commerce of Spain, dated March, 1924. By Capt. U. de B. Charles, C.B.E. Department of Overseas Trade. Pp. 79. H.M. Stationery Office, 1924. Price 2s. 6d. net.

Publication of the Department of Commerce, Bureau of Foreign and Domestic Commerce. Washington: Government Printing Office, 1924 :—

The German Dyestuffs Industry. By T. W. Delahanty. No. 126. Pp. 62. Price 10 cents.

Publications of the United States Department of Commerce. Washington: Government Printing Office, 1924.

Elimination of Waste. Simplified Practice. Pp. 8. Price 5 cents.

Publications of the United States Geological Survey. Department of the Interior. Washington: Government Printing Office, 1924 :—

Gold and Silver in 1922 (General Report). By J. P. Dunlop.

Mineral Resources of the United States, 1922, Part I. Pp. 595—635.

Production of Sulphate of Ammonia for 1923. Pp. 11. New York: The Barrett Co.

Das Leitvermögen der Lösungen. Parts II and III. Handbuch der Allgemeinen Chemie IV. 2s. 3d. By Prof. P. Walden. Pp. vi+399. Leipzig: Akademische Verlagsgesellschaft m.b.H., 1924. Price, paper, 47 goldmarks; Bound, 50 gm.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council of Pure and Applied Chemistry

which consists of Representatives from

The Chemical Society, the Society of Chemical Industry, the Association of British Chemical Manufacturers, the Institute of Chemistry, the Society of Public Analysts, the Faraday Society, the Institute of Brewing, the Society of Dyers and Colourists, the Society of Glass Technology, the Iron and Steel Institute, the Ceramic Society, the Institution of Gas Engineers, the Society of Leather Trade Chemists, the Royal Photographic Society, the Mineralogical Society, the Biochemical Society, the Institute of Metals, and the Royal Agricultural Society.

VOL. 43 NEW SERIES — LONDON, AUGUST 15, 1924 — NO. 33

EDITORIAL

THE Ministry of Health is surely a little inconsiderate. Only a fortnight or three weeks ago two scientific professors commented somewhat adversely—so it seemed to us—on the merits of a preparation in which formaldehyde or a polymer of it played some part. The justification for their comments is to be determined by His Majesty's judicial department, and before the decision can be arrived at the Ministry of Health issues a report on food preservation, in which an attack is made on the unfortunate formaldehyde. The report states that it is "a preservative which is inimical to life and to vital processes of all kinds. It is a powerful protoplasmic poison" and so on. The committee in charge of this matter even goes so far as to recommend that the "treatment of meat or the addition of formaldehyde or any of its derivatives to food or drink should be absolutely and specifically prohibited," and states that this preservative may retard digestion even when present in food in comparatively great dilution and that its effect is probably cumulative. The application of chemistry to the service of man grows steadily in importance and, in relation to health and the cure of disease, there is no doubt that the chemist has already been responsible for achievements which are marvellous. Many of our most serious diseases are caused by the presence of bacteria and of other organisms, both animal and vegetable, in the system. The chemist and the physician are continually searching for a drug which will kill these organisms before it will kill the patient, even before it will seriously injure his health. Some of these drugs are singularly capricious in their tastes; there are dyes which will stain cotton and not silk, there are other dyes which will exercise strange selective actions of another variety. So there are drugs which kill one sort of organism and leave many others unaffected. What is one germ's meat is another germ's poison. At this time of the year the ravages of small animals in a garden point the way to making a fortune for the chemist who will deal with such pests. "That which the palmer-worm hath left hath the locust eaten; and that which the locust hath left hath the canker-worm eaten; and that which the canker-worm hath left hath the caterpiller eaten." But we fear formaldehyde is too dangerous a drug even for the garden.

* * *

We have enjoyed reading a pleasant book by John O'London called "Is it Good English and Like Matters." The laws and conventions which regulate a living language such as our own have for many years interested us. The laws of grammar are to be found in many books, the majority of which are unreadable, the conventions are to be found in the writings of every author who tries to write in the manner of good writers. The laws and the conventions do not invariably agree. This is true of countries as well as languages: the British constitution is full of conventions which have no legal force, but the consequences of breaking them are so serious that in practice they are not disregarded. It is a mere convention that a bill in Parliament must be read three times in the House of Commons before it is passed there. The existence of a Prime Minister and a Cabinet, their functions and responsibilities, the powers of individual Ministers and the relations of the Government of the day to the Crown, are almost exclusively determined by convention. So too in the use of words in our language; the grammarians have given us their rules and regulations but the dominant power which compels us to avoid certain phrases or constructions is the public opinion of those who are supposed to be good judges of literary manners. John O'London's little book is well printed and costs only a florin; it is full of good points and is neither didactic nor pedantic. The author recognises the changes in fashion and the impossibility of restricting the liberty of writers in minute points. Every writer must be allowed a few fads of his own and these vary in accordance with the period and nature of his education, the choice of his favourite authors and his own idiosyncrasies. The standard of writing to-day is a high

one: we can recall very few authors of fifty or a hundred years ago who seem to be as fastidious as many of our present writers.

* * *

A few weeks ago we read in this *Journal* a note on the chemistry of bread which included a reference to the composition of starch. We were naturally very glad to see in this month's Journal of *The Institute of Brewing* a considerable paper by Professor A. R. Ling on "Some Recent Contributions to our Knowledge of the Chemistry of Starch." Professor Ling has studied this question for many years and done much in company with other British chemists to extend our knowledge of this material. Mr. Cornelius O'Sullivan, Dr. Horace Brown, Mr. Julian L. Baker and Professor Ling have made an interesting contribution to our science. We intend to publish a summary of Professor Ling's paper at an early date, but those who have a knowledge of the chemistry of carbohydrates will do well to consult the original paper During the last twenty years how much additional understanding of sugars, starch and cellulose has been attained! With the progress made also on insulin and its effect on the carbohydrates in the animal world, we are getting to know the part played by carbohydrates in life, not only why they act, but also how.

* * *

It was a fortunate coincidence that, unknown to each other, both the Society of Chemical Industry and the Chemical Industry Club chose November 14 as the date for their respective dinners. So soon as this was found out a desire was expressed to have a combined dinner, instead of two separate ones, and this has now been agreed A preliminary announcement of the dinner appears in this issue, and the details are being arranged by representatives of the Society and the Club. There were two Kings of Brentford, but their kingdom was not a success, there are joint managers of some companies and joint secretaries of some societies, but we cannot recall any dinner presided over by two chairmen It is as awkward for two chairmen to get up at the same time and say, "Ladies and Gentlemen, the King," as it would be for two sergeants to drill simultaneously the same squad. Mr Coley, the genial Chairman of the Club, solved this delicate problem, which has wrecked many a combined effort, by generously consenting to play the second fiddle. He can well afford to do so for his position in the Club is unique. He was the founder of it, the prime cause of its existence; he is the Chairman of it, and presides over its meetings with skill and tact, carefully avoiding partiality on the one hand, and impartiality on the other hand, and he will in the future retain in the hearts of his fellow members that affection which is the due of a really clubbable man It will be good for the Society and good for the Club, to have greater community of interest than has prevailed hitherto, the dinner will undoubtedly be a great success, and we shall expect from Mr. Woolcock, who will take the Chair, and from Mr. Coley, who will have the option on any other chair, speeches suitable for this memorable occasion.

CHEMISTRY AND THE STATE *

By SIR ROBERT ROBERTSON, K.B.E., F.R.S.

(Continued)

Health

The earliest legislation in respect of food dealt with articles from the Revenue standpoint rather than from that of safeguarding users against adulteration. Thus, the Adulteration of Coffee Act of 1718 refers to evil-disposed persons who make use of water, grease, butter and such-like materials for addition to coffee, "whereby the same is rendered unwholesome and greatly increased in weight, to the prejudice of His Majesty's Revenue and the health of his subjects." Similarly, the Tea Act of 1730 refers to the use of various materials and operations for sophisticating tea, "to the prejudice of the health of His Majesty's subjects and the diminution of the Revenue." The Tea Act of 1776, which deals specifically with the preparation of other leaves for use in imitation of tea, gives as an additional reason, "the injury and destruction of great quantities of timber woods and underwoods."

Since this legislation was mainly for the prevention of fraud on the Revenue, it was left to the Crown to ascertain the purity of the articles in question. To this end the Inland Revenue Laboratory, which was established in 1842 primarily for testing tobacco, became also the laboratory for the analysis of dutiable foods, such as tea, coffee, pepper. In this connexion it is of interest to note that the Government at times sought assistance from distinguished chemists not on its staff, as when Thomas Graham at University College, London, carried out for the Board of Inland Revenue an inquiry into the chemical means of detecting vegetable substances mixed with coffee for the purposes of adulteration. Among the early pioneers in the chemistry of food may be mentioned Dr. Hassall, who was the analyst of the "Lancet Sanitary Commission," and published the reports of that body on "Food and its Adulteration."

Besides the enactments with regard to certain dutiable foods referred to above, legislative action was taken with respect to bread, the Bread Act of 1822 dealing with the sale of bread in London and district, and that of 1836 with the sale of bread outside the London area. There was no provision for analytical examination of samples under these Acts, which still remain in force.

By the efforts of Lyon Playfair on matters of sanitation and the work of the Royal Commission on the Health of Towns of which he was a member, public opinion was being awakened during the 'forties to the social importance of the health of the community, a movement in which the Prince Consort took an enthusiastic part. This led to the Commission of 1869 and the foundation of the Local Government Board, through which the safeguarding of public health in England was systematically organised. From this Board and its successor, the Ministry of Health, a series of useful reports on questions of food have issued, most of which have involved chemical investigations.

* Presidential Address before Section B (Chemistry) British Association, Toronto, 1924.

In 1855 and again in 1856 a Committee was appointed by Parliament to inquire into the "Adulteration of Food, Drinks and Drugs." It was evident to these Committees that some provision for the chemical analysis of samples was necessary, but they made no provision for samples to be taken. This and other matters were provided for in an amending Act, which came into force in 1872. A Select Committee of Parliament was appointed in 1874 to inquire into the working of these Acts, and as a result of their report another Act, that of 1875, was substituted. By this Act the Local Government Board was given power to require evidence of competence from analysts, and the Inland Revenue (now the Government) Laboratory was appointed as the authority to which Courts of Law could refer disputed cases.

The Act of 1875 has been amended and extended by the Acts of 1879 and 1899, and other Acts have been associated or incorporated with it, such as the Margarine Act (1887) and the Butter and Margarine Act (1907), the whole series being quoted collectively as the Sale of Food and Drugs Acts, 1875-1907.

The provisions in the above Acts affecting chemists may be summarised as follows: (1) the appointment of public analysts by the local authorities is compulsory; (2) the Ministry of Health and the Ministry of Agriculture (when the interests of agriculture are in question) have power to step in if the local authority fails to utilise the services of the public analyst; (3) the appointment and dismissal of a public analyst by a local authority are subject to the approval of the Ministry of Health; (4) the analyst must afford the Ministry evidence of his competence for the work. It is the practice of the Ministry to accept for such purpose the Diploma of the Institute of Chemistry, together with the Certificate of that Institute in Therapeutics, Pharmacology and Microscopy.

The position of the Government Chemist in the administration of the Acts is as follows. (1) the Acts provide that in the hearing of any complaint in a court of justice the magistrates must, at the request of either party, and may themselves without any previous request, send the reserved portion of the sample to the Government Chemist for analysis. This provision is taken advantage of in a number of cases each year, and gives rise to a considerable amount of interesting work relating to methods of analysis, the alteration in food on storage, and the figures to be taken as standards for genuine articles. The necessity for such investigation is at once apparent in the case of milk, since samples cannot under ordinary circumstances reach the laboratory before the expiry of at least three or four weeks, and the fermentation that has taken place in this time has resulted in the loss of solid matter.

(2) The Acts provide for the examination at the Government Laboratory of samples of imported tea, margarine, and various dairy products, the object being (*a*) to prevent adulterated food of this character entering the country, and (*b*) to ascertain whether it conforms to the standards laid down for such food.

It may be pointed out that there is nothing in the United Kingdom corresponding with the series of food definitions and standards which exist in some of our Colonies, and in a marked way in the United States. The main provisions of these Acts are briefly that (1) no person shall mix any article of food with any ingredient so as to render the article injurious to health, and (2) no person shall sell to the prejudice of the purchaser any article of food which is not of the nature, substance and quality demanded by such purchaser. A few definitions and standards are, however, given in the Acts, and these have been added to by Regulations under the Acts, or by Regulations made under the Public Health (Regulations as to Food) Act, 1907, the Licensing Act, 1921, and the Milk and Dairies Act, 1922. Before regulations on questions of limits have been issued, it has been customary for the Crown to institute an inquiry into the particular subject.

A brief summary of the definitions and standards thus fixed is as follows:—(1) The strength of spirits must not be reduced more than 35 degrees under proof; (2) standards have been fixed for milk, separated milk, condensed and dried milks; (3) limits have been set up for water in butter, milk-blended butter and margarine, and for butter fat in margarine; (4) the addition to milk of water, preservative, colouring matter, separated or reconstituted milk is prohibited; (5) cream must not be mixed with a thickening substance, and the conditions with regard to the addition of preservative to it have been fixed.

In its care for the purity of drinking water the State has made several enactments. It may be said that this country led the way as the result of the great work of Frankland in devising means for determining the potable qualities of water, and in pressing for pure supplies. An enormous volume of useful work was carried out by the Royal Commission on Sewage Disposal of which Ramsay was a member. This sat from 1898 until 1914, when it dissolved, having projected further work on industrial effluents and their effect on river water, work which is just recently being followed up by an Advisory Committee to the Ministry of Agriculture and Fisheries.

The contamination of the atmosphere is a subject of concern to the Ministry of Health working under Acts from 1863 onwards. Limits have been set to the discharge of noxious and offensive gases, and the control is in the hands of a number of chemical inspectors, who have in addition carried out a large number of investigations of importance to general health and to industry. The contamination of the air in cities is watched by the Meteorological Office, which records the quantity of soot falling in different parts of the country. By such means the public conscience is being awakened to the necessity for the provision of a smokeless fuel, a subject engaging the attention of the Government Fuel Research Station.

Chemical control is also concerned with the question of danger to health arising in certain trades, such as that of the manufacture of matches, in which red was substituted by law for white phosphorus, with the limitation of lead in glazes, with the nature of the gases in mines, and with manufactures in which poisonous substances such as nitrobenzene and nitrous fumes are produced.

In 1900 there was a serious outbreak of sickness attributable to poisoning by arsenic, and a Royal

Commission was appointed to inquire into the cases and to ascertain by what safeguards the introduction of arsenic into food could be prevented. A very large amount of chemical work was carried out in connexion with this inquiry, and considerable attention was paid to the methods for the detection and examination of arsenic. Among those contributing specially to the problems may be mentioned Dr. George McGowan, the Government Laboratory, and a Joint Committee of the Societies of Public Analysts and Chemical Industry. At the Government Laboratory an electrolytic apparatus was devised in which the use of zinc for the production of hydrogen was not necessary. This apparatus has been modified by replacement of the expensive platinum cathode originally used by lead coated with mercury, which has been found to give very satisfactory results.

It was not until the end of 1916 that the control of the food supply of the country passed into the hands of a Ministry of Food. In the meantime much work of a scientific nature had been done in the way of endeavouring to educate the people on food values. A pioneer in this direction was Prof. W. H. Thompson, who occupied the Chair of Physiology in Trinity College, Dublin, and who became later Scientific Adviser to the Ministry of Food. He was unfortunately lost in the sinking of the Irish mail boat in which he was a passenger. Thompson communicated to the Royal Dublin Society early in 1915 an important paper dealing with the energy value and chemical constitution of foods, subsequently published as a pamphlet under the title of "The Food Value of Great Britain's Food Supply." The question of the food supply of the United Kingdom was receiving attention in 1916 from a Committee of the Royal Society which included among its members distinguished chemists, and at the request of the Board of Trade the Committee drew up a report on the food supply in which much of Thompson's work was incorporated. It is interesting to note that in the main the values given by Atwater in the "Chemical Composition of American Food Materials" were followed in the calculations. There can be little doubt that the decision of the Government to recover a larger proportion of the grain for human food in milling wheat, and to restrict the use in brewing and distilling of materials capable of use as food, arose from the suggestions put forward by this Scientific Committee.

The chemical examination of the enormous quantities of food, together with the inspection of the packing and the testing of materials used for the purpose, forwarded overseas from this country for the Army in the war was entrusted to the Government Laboratory. Chemists were established at the various receiving depots, and all goods delivered by contractors were inspected, and, if considered necessary, sampled and analysed as to their conformity with specification. The chemist reported upon each delivery before the Army authorities proceeded to issue it.

The Medical Research Council, now under a Committee of the Privy Council, deals with subjects coming within the province of biochemistry, and the organic chemist has here an opportunity for preparing substances which the knowledge now available indicates as likely to be of value in combating, for example, diseases due to blood parasites.

Agriculture

The connexion of the State with scientific agriculture goes back to the beginning of the nineteenth century. The period from 1770 to 1820 was one of great activity in agricultural development. It was then that several of the oldest agricultural societies were formed, and the Chair of Agriculture and Rural Economy founded in Edinburgh University.

The first Board of Agriculture was formed in 1793, and it was to this Board that Humphry Davy, himself one of its members, delivered during the years 1802-1812 the courses of lectures which were afterwards published under the title of the "Elements of Agricultural Chemistry." Davy in his introductory remarks dealing with the object of the lectures sets out clearly what he understood by agricultural chemistry—it "has for its object all those changes in the arrangement of matter connected with the growth and nourishment of plants; the comparative values of their produce as food; the constitution of soils; the manner in which lands are enriched by manure, or rendered fertile by the different processes of cultivation." This statement sets forth the position to-day, and in the progress that has been made towards the attainment of these objects the chemist has played an important part.

Although Davy quotes the results of his chemical work on a series of grasses, no great advance was made for many years, and when it did come it was at the instance of private enterprise. To John Bennet Lawes, the founder of Rothamsted, is due the initiation of experiments which began in 1834 and have continued uninterruptedly until to-day. Joseph Henry Gilbert joined Lawes in 1843, and the association of the two was not broken until Lawes' death in 1900. When Gilbert died in 1901, Sir A. D. Hall became director, and he was succeeded in 1912 by the present director, Sir John Russell.

The next experimental station in England was that founded by the Royal Agricultural Society, on the Duke of Bedford's estate at Woburn under the direction of Dr. A. Voelcker, and now carried on by his son Dr. J. A. Voelcker. The Royal Agricultural College at Cirencester was founded in 1845.

The development of the scientific study of agriculture was thus left largely to such institutions as that of Rothamsted, and to certain agricultural colleges which did not receive State aid.

The first legislative action on behalf of agriculture with which the chemist was concerned was an Act for the protection of the agriculturist against fraud from the purchase of inferior or worthless manures and feeding stuffs. By the Fertilisers and Feeding Stuffs Act of 1893, superseded by the Act of 1906, the seller of artificial fertilisers and certain classes of artificially prepared feeding stuffs was compelled to give with the goods an invoice guaranteeing the percentages of specified constituents on which the value of the article depended, and county authorities were required to appoint agricultural analysts for the purpose of checking the statements on the invoice by analysis of samples. The Board of

Agriculture also appointed a chief analyst who was required to analyse the reserved samples in cases where discrepancies were of such a nature as to lead to the possibility of proceedings in Court.

It will thus be seen that, with the exception of the encouragement given to the work of Davy, the first State action was not towards the development of agriculture, but for the repression of fraud. There were, however, movements from time to time in the direction of scientific inquiry into problems connected with agriculture, such as investigations into the effect of food and breed on milk, and into the efficiency of sheep dips, with both of which the Government Laboratory was closely associated.

No systematic educational work in scientific agriculture was attempted in Great Britain before 1909, when an Act was passed allocating annually the sum of £500,000 for "aiding and developing agriculture and rural industries by promoting scientific research, instruction and experiments in the science, methods and practice of agriculture (including the provision of farm institutes)." Under this Act, a system of agricultural research was framed, based on university and on research institutions like Rothamsted, and linked up with the agricultural colleges. The scheme formulated enabled the Development Commissioners appointed under the Act to form new institutes as well as to extend the existing ones. Rothamsted was largely extended, and increased facilities afforded for work on Plant Physiology (Imperial College), Plant Breeding (Cambridge University), Animal Nutrition (Cambridge), Dairying (Reading), Animal Pathology (Royal Veterinary College), and on similar subjects. In many of these the chemist was essential. Another part of the scheme was the foundation of scholarships awarded to selected graduates of universities tenable for a three-year course of research. In certain selected teaching institutions technical advisers for farmers were appointed, and researches not capable of being pursued at an institute were maintained elsewhere.

The provision of this scientific work for the benefit of agriculture is carried out by the Commissioners through the medium of the Board of Agriculture, with which policy is discussed and details arranged. It represents the first co-ordinated attempt by the State in the United Kingdom to secure a comprehensive scientific study of the problems of agriculture, and the first systematic endeavour to apply scientific method to the development of agriculture. Results followed at once, and as an illustration it may be pointed out that in the eight years from 1912 to 1920 Rothamsted issued, in spite of the adverse effects of the war, 75 scientific papers, published eight books, and contributed numerous articles for farmers and teachers, and the Cambridge Animal Nutrition Station also published 60 papers in the same period. Other institutes also contributed to knowledge on this subject.

During the war, agriculture in this country was affected in several ways—for example, by (1) shortage of the usual feeding stuffs for cattle, and (2) shortage of fertilisers, particularly potash and nitrogen, both as nitrates and ammonium salts. At the same time there was a demand for an increased production owing to the diminished supplies of essential foods from abroad.

The attention of chemists was directed to these points. Fortunately the research institutes provided by the funds of the Development Act referred to above were in existence and available for making investigations. Thus the staff at Rothamsted under Russell gave special attention to the shortage of manures and prepared monthly notes for the guidance of farmers, while the Animal Nutrition Institute at Cambridge under T. B. Wood provided monthly notes on the uses of available feeding stuffs. In the latter part of the war, conferences were held weekly at the Food Production Department in which research workers from the institutes took part. These meetings had such value that the Ministry of Agriculture and Fisheries have now constituted an Advisory Council in Agricultural Research at which the directors of the institutes meet periodically to review the progress being made.

When the war-time requirements of nitrogenous fertilisers are considered, it is significant that the production of nitrogen in the form of ammonia showed no increase in the first years of the war, and only a six per cent. increase in 1917 over 1913. The restriction of nitrate supplies for munitions caused a greater demand for nitrogen in the form of ammonia, and it may be expected that in the future even larger quantities will be needed. The Nitrogen Products Committee estimated that the possible demand in the near future for artificial nitrogenous fertilisers for the United Kingdom would be 100,000 tons of nitrogen, or four times the quantity used in 1913.

Of the fertiliser ammonium sulphate, we produced before the war five times as much as we required for our own use, but we imported also over 100,000 tons a year of sodium nitrate from Chile. During the war the importation of this salt was quadrupled and nearly all was taken up for munitions, being converted into nitric acid for the purpose of nitrating glycerine, cotton, toluene and phenol, and made into ammonium nitrate for the explosive amatol. All our explosives therefore depended on the importation of Chile saltpetre, a condition of affairs which gave rise to great anxiety. Although we still had sufficient ammonia, there was no plant available for oxidising it to give the nitric acid required. As no sodium nitrate could be spared for agriculture, its place was taken by ammonium sulphate, of which increasing quantities were used for manuring the soil to obtain increased productivity. At the same time this salt was being increasingly used for making ammonium nitrate, so that the time approached when, in place of the ample margin before the war, a shortage of ammonia was in sight.

The claim of munitions on sulphuric acid also materially reduced the quantity of ammonium sulphate as well as of superphosphate by about 40 per cent., and chemists had to devise means for using nitre-cake in its place in the manufacture of these fertilisers.

Anxiety as to the want of capacity of the country for fixation of atmospheric nitrogen had led in June, 1916, to the foundation of the Nitrogen Products

Committee, the results of whose labours will be found in a massive Blue Book full of information on statistics, on processes, and on the comparative merits of methods for developing power. A staff of chemists and physicists attached to the laboratory of this Committee was actively engaged on investigations on the conditions of manufacture of ammonia by the Haber process, as well as in determining the physico-chemical constants of the gases involved. Much valuable work was accomplished both on the combination of hydrogen and nitrogen and also on the oxidation of the product to nitric acid, so that the Committee was able to recommend the erection of a trial plant in February, 1917, and by October of that year the Department of Explosives Supply recommended the process worked out for adoption in a national factory, and a start had been made towards its erection at the end of the war.

This project was taken over by Synthetic Ammonia and Nitrates, Ltd., which has continued the research work and erected the large-scale plant. It is satisfactory to be able to announce that, instead of being about the only great nation not engaged in the fixation of nitrogen from the air, we have now in Great Britain a plant producing at the moment 150 tons of synthetic ammonia a week. From the point of view of agriculture as well as of national defence, this cannot fail to afford a fresh, if somewhat delayed, confidence.

The shortage of potash supplies was apparent soon after war broke out, since nearly all potash came from Germany. Attention was immediately drawn to other possible sources of supply and to means whereby the potash in stable combination in the soil might be made available. Russell at once called attention to the potash salts in the ash of sea-weed, bracken, hedge-clippings, wood-waste, and similar substances, and, he also advised the use of lime, and in certain circumstances of sodium salts, whereby potash in the felspars and clays became available.

Numerous suggestions put forward as to possible sources of supply of potash were inquired into. In one interesting case, where a small-scale plant was put into operation under the supervision of the Government Laboratory, a good yield of potash was obtained from felspar, but the process involved the production as a by-product of so large a quantity of an inferior quality of cement that unless a market could be obtained for this there was no possibility of working the process successfully.

A source of supply that was used to a certain extent was the flue-dust of furnaces, which was found to contain a fair though variable quantity of potash. Considerable developments were made by Mr. Kenneth Chance, of the British Cyanides Co., in the direction of obtaining from the ores dealt with in the United Kingdom a large supply of potash, and an extensive scheme of operation was contemplated before the Armistice.

Another direction in which supplies became restricted was in respect of phosphatic manures. Importation of bones, mineral phosphates, and guanos, owing to war conditions, could not be maintained, and, owing to the demand for sulphuric acid for essential munitions of war, the supply for manufacture of superphosphate was strictly limited. Hence attention was directed to the examination of the results obtained by using finely ground natural mineral phosphates and basic slag. These insoluble phosphates were found to possess a greater value as fertilisers than had been thought.

The shortage of food-stuffs for cattle arose partly from decreased imports, particularly of linseed, cottonseed and grain, and partly from causes within the country, as for example the dilution of flour with maize and other cereals and the milling of the grain to obtain an increased percentage of flour for human food, whereby the quantity of milling offals was reduced. The attention of chemists was at once directed to the question of new or hitherto little used food-stuffs. For some years prior to the war the importation into Continental countries, particularly Germany and France, of valuable oil-seeds had been rapidly increasing, thus providing oils for margarine manufacture and valuable cakes and meals as food for cattle. The case of palm-kernels, a valuable source of oil and cake, is a striking one, for British West Africa exported before the war about 230,000 t., of which 35,000 t. came to England and 181,000 t. to Germany, and a similar condition applied to copra, earth-nuts and sesame seed. These and many other seeds began to be diverted to the British market, and the cakes or meals, after examination of feeding value, formed a useful addition to the food supplies, as was illustrated by the great increase in the manufacture of margarine.

Home supplies were also explored, materials which had hitherto been discarded were tried, and waste material from a variety of sources was utilised. In all this the work of the chemist was essential. The elucidation of the composition of the material, of the digestibility coefficients of its various constituents, and of its feeding value was the contribution of the chemist to this great problem of the nation.

Since many of the war-time expedients mentioned above were of a makeshift character, it is not surprising that they did not survive when normal economic conditions arose. Thus, when sulphuric acid again became available, the troublesome use of nitre-cake was abandoned and blast-furnace flue-dust was no longer collected. It was disappointing that the nitrogen fixed in the large surplus stocks of explosives, both in the form of nitric esters and of nitrogen compounds, could not profitably be utilised. Many of the difficulties were overcome in the case of the nitric esters by the application of a process of alkaline hydrolysis, but the attempt was abandoned on account of the difficulties which arose during process in freeing the product from poisonous impurities and in putting it on an economic basis.

The war-emergency work has had some lasting effects, of which may be mentioned the development of a process for making "synthetic farmyard manure," the increased use of basic slag as a phosphate fertiliser, and the increased attention that is being devoted to the newer nitrogenous fertilisers, more particularly those produced by fixation of atmospheric nitrogen.

The lessons of the war have not, however, been entirely lost. The last report of the Development

Commissioners, for the year ended March 31, 1923, shows advance in every direction. In addition to the sum available from the Development Fund of the Act of 1909, it was possible to make increased grants owing to the money received under the Corn Production Acts (Repeal) Act, 1921. The special fund enabled grants to be made for additional research, as, for example, the extension of the advisory scheme in connexion with agricultural research, the provision of scholarships for children of agricultural workers, and the endowment of a Chair in Animal Pathology at Cambridge. In order to prevent overlapping and to secure co-ordination, the Development Commissioners are working in consultation with the Medical Research Council and the Department of Scientific and Industrial Research.

It may be said that the greater part of the work on agricultural chemistry since the war has been of a fundamental nature, the results of which have not yet become capable of translation into agricultural practice, although they may be expected to exert ultimately a powerful influence on farming.

Other Activities

In addition to the activities that have been grouped under the respective headings, there are many others bearing on State problems which have occupied the attention of chemists.

Thus, expeditions, such as that of the *Challenger*, have been fruitful in results of chemical work. The investigations of Dittmar on the composition of sea-water and of Murray on mineral phosphates may be recalled in this connection.

For data on the chemical composition of rocks the Geological Survey is indebted to the work of Percy, Dick and Pollard, and for work on the formation of igneous rocks to Teall, Harker and Flett. The remarkable experiments of Sir John Hall on rock-formation at the beginning of the nineteenth century have been described in a recent British Association address. On several occasions the choice of building-stone, especially for the Houses of Parliament, has been before groups of geologists and chemists, especially with respect to the action of atmospheric impurities, and, although the causes of decay are fairly clear, its arrest still forms a difficult problem.

The difficulties in selecting colours sufficiently fugitive to prevent the removal of obliteration marks from postage and fiscal stamps were to a large extent solved by the activities of Warren de la Rue.

Investigations on such matters as the above for various Departments of State form part of the work of the Government Laboratory, which in addition, during the war, had to advise concerning the conservation of materials, the control of imports and exports by the War Trade Department, and on the nature of contraband goods.

Organised Applied Research

In the middle of 1915, at a time when our shortage of many essential materials brought out the need for the application of more scientific methods to our industries, if we were to succeed in competition with other countries after the war, the Department of Scientific and Industrial Research was founded. It set out to assist firms in an industry to co-operate with one another and employ a staff of scientific men to solve their problems and develop their industry, to assist other Government Departments desirous of having investigations carried out, to organise research into problems of practical utility of wide importance, and to foster the prosecution of researches in pure science. With the exception of the last, these aims can be considered as coming under the designation of organised applied research. The Department has always strongly insisted that it is this type of work only that it seeks to organise, the assisted worker in pure research being left entirely free to follow his bent. As regards scientific policy, the Minister in charge of the Department is advised directly by a Council of independent scientific men, and these are represented also on the various Boards and Committees entrusted with the supervision of such investigations as are directed by the Department itself.

Research Associations.—From the success attending applications of scientific research in military and industrial problems during the war, the lesson was drawn that our industries in peace-time should be infused with fresh and more vigorous life by methods which had proved their worth at our time of need. Foresight in these matters was necessary, since it behoved Great Britain, no longer with the industrial world at its feet, to make the utmost use of its resources, by adopting the methods that were most efficient and solidly based on science, in order to produce material that would maintain the tradition of the excellence of British goods. While it was recognised that the most powerful chemical industries maintained efficient research staffs, it was decided to encourage separate industries to organise themselves for the co-operative prosecution of research. To the associations erected under this scheme grants, for a term of years only, and usually on a pound-for-pound basis, are made from a fund of a million pounds voted by Parliament in order to demonstrate to the industries the advantage of investigating their own technical problems, for it was recognised that many industries would have to carry out research themselves before they could properly appreciate its application. In its last published Report the Department remarks on the continuance of these grants to the associations beyond the originally intended period of five years, as this period has proved insufficiently long for the equipment of laboratories and the effective launching of important investigations, especially during a time of industrial depression.

A very wide field is covered by the research associations. Among those that have been set up in which chemistry is important are associations for the textile industries, for rubber, leather, and shale oil, for flour and sugar, for non-ferrous metals, cast-iron, glass, refractories and Portland cement, and for scientific instruments and the photographic industry.

As the results obtained by the associations are primarily for the benefit of their constituent members, the onlooker has a chance of gauging the chemical work carried on only from the communications which, following an enlightened policy, the management of some of them permits to be published; and as many of these are contributions to "pure" chemistry, an example is afforded of the opportunity as well as

of the necessity for work of this kind in the case of investigations undertaken primarily for an industrial purpose.

It would be impossible to review the work of the research associations for all these industries, even if the data were available, and so reference will be made only to some of their publications, relating to textile fibres, cotton, flax, wool and silk, as the work published presents many intesting features. Thus there are being studied the products of the hydrolysis of cotton, with an obvious bearing on the constitution of cellulose, the chemical constituents of cotton waxes, and the action of micro-organisms on cotton fibres and fabrics. Flax, hemp and ramie fibres are being investigated as to their distinguishing characteristics and behaviour with reagents that affect their lustre and absorption of dyes. Wool has been found to have a selective action, whereby it absorbs the alkali from the soap used in scouring, and methods have been evolved for accurately following the action in practice. Similarly with silk, a systematic study is being made of the action of acids and alkalis on the components of this fibre. In the respective laboratories the chemical and physical properties of each of these fibres are being studied and correlated for the purpose of explaining, for example, their strength and lustre, and at a recent meeting of the Faraday Society the methods and results of workers in all these fibres were reviewed in a General Discussion.

A close scientific scrutiny is being applied to the tanning of leather, and the chemical and physical changes involved, together with a bacteriological study of the process. Equally important for this industry and for that of making photographic plates is the study of gelatin, whose chemical and physical properties are being elucidated, whilst work of benefit to pure science has been published on the effect of light on the photographic plate. The study of the chemistry of glass and the physical properties associated with changes in its composition is another another example of work that has been reported in the literature for improvement of an industry.

The record, as has been stated, must be incomplete but the subjects mentioned present the appearance of being valuable in the scientific study of material and process, and can scarcely fail to lead to the betterment of the respective industries.

Boards.—The Boards and Committees under the Department may be broadly divided into those which undertake the investigation of work of national importance, and those which undertake work of specific importance to Government Departments and correlate the scientific work that these carry out.

A large amount of chemical work is carried out by these Boards. The Departmental Research Boards and Committees dealing with chemical subjects are concerned with the cause of the deterioration of fabrics by organisms and light, and their fireproofing; with the changes that food undergoes under varying conditions of storage, and the constitution of fats; with the chemistry of the treatment of timber; with the survey of our coal resources and the economic usage of coal; with the production of alcohol and liquid fuel from waste vegetable matter; with the chemical aspects of the problems of adhesion, lubrication, restoration of museum exhibits; with building materials, paints, and the preservation of stone, and with the properties of several of the minor metals. For subjects of the magnitude and importance of some of these, staff and equipment have in several instances been provided on a large scale, and a growing number of monographs and communications to the literature issues from the respective Boards.

The Co-ordinating Board for Chemistry, like the similar Boards for other sciences, was founded for the purpose of securing interchange of information among Government technical establishments, seeing that outside interests are informed, when this is practicable, and arranging for researches not otherwise provided for. The Board carries out these duties in consultation with representatives of the Fighting Services and of other Government Departments materially affected, and with independent chemists, when departmental schemes of work are reviewed in the light of information that may be in the possession of any of the members of the Board. To this Board are referred questions of wider importance than are within the purview of any one Department, and it keeps under its consideration the development of the natural resources of the country. With further facilities for undertaking investigations, it will be in the position to extend such work and to arrange for subjects not otherwise provided for, as well as for those at present under investigation.

Assisted General Research

Apart from the indirect help afforded to the universities by means of Government Grants, direct assistance is given by the Department of Scientific and Industrial Research to research workers who may be students, or independent workers, and to important pieces of pure research. To these grants no conditions are attached; they are given for the extension of knowledge.

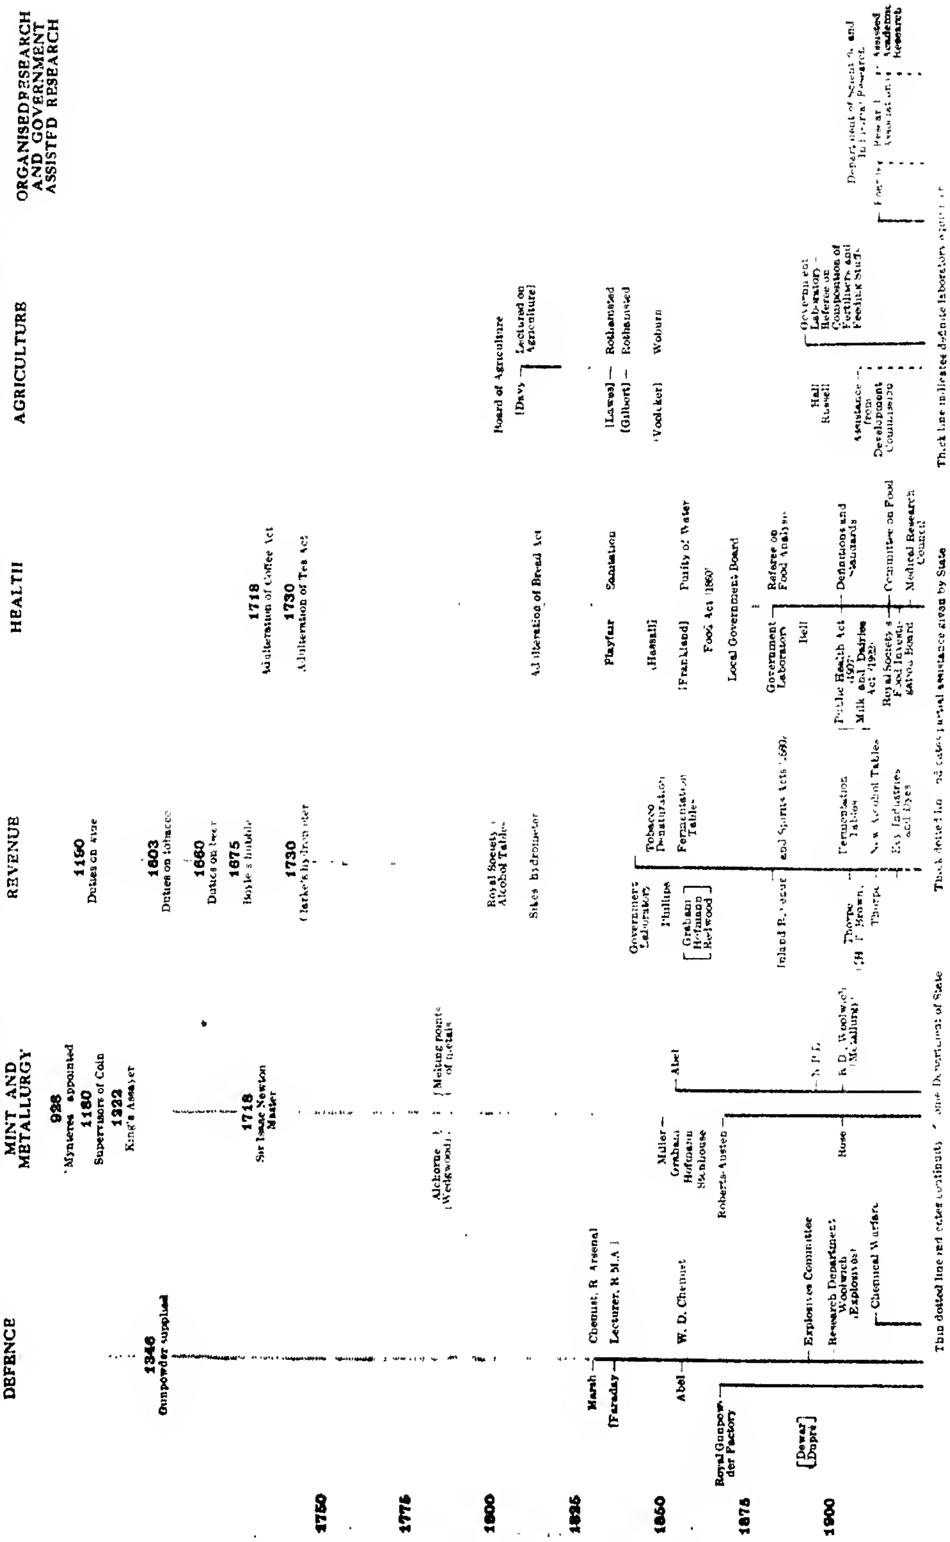
One of the objects of these grants is to encourage the supply of highly-trained scientific research workers to meet the growing needs of the Government, the industries of the country, and indeed of the Empire. The lack of such was felt acutely during the war, although now, for chemists with the usual qualification at any rate, the conditions have changed.

Students are given grants on the recommendation of their professor that they are a type likely to be greatly benefited by spending two years at research work after taking their degree. In this case the award is for promise and not for achievement, and the hope is entertained that the necessity for these grants will gradually disappear when university finance is on a sounder basis.

Grants are given to independent workers who have shown their capacity for research, and who are handicapped by lack of facilities. Further, for work of unusual importance, substantial financial assistance may be given when it appears desirable.

In this way comes recognition of the national importance of the highest type of scientific work, and to this, of course, no conditions are imposed as to the lines on which it should be carried out.

CHART SHOWING DEVELOPMENT OF STATE'S ACTIVITIES IN CHEMISTRY IN THE UNITED KINGDOM



SUMMARY

The State's appeal to chemistry has developed through the gradual recognition of the need for the application of that science to matters relating to its preservation, its currency, its financial support, its health, its food supply, its industries, and finally to academic science. A chart illustrating this development historically is appended to this address.

In the course of this development, advantage has been taken, if sometimes tardily, of the general advance in chemical knowledge, and frequent recourse has been had to the advice of well-known chemists of the day, and collectively of the Royal Society; thus for various purposes the following chemists, as officials or consultants, have in the past afforded assistance in the solution of specific problems referred to them, or by taking part in Commissions: Boyle, Newton, Davy, Faraday, Daniell, Graham, Hofmann, Redwood, Abel, Roberts-Austen, Percy, Dupré, Playfair, Frankland, Ramsay and Dewar. It has happened in several instances that as a result of these Commissions and references to chemists some definite chemical activity of the State has emerged.

It will be convenient in this summary to review the State's chemical activities before, during, and after the war.

BEFORE THE WAR

Defence.—For its defence, establishments for the production of explosives were early maintained, and when this ultimately took the form of a chemical manufacture the Government factory took the lead in devising efficient processes, while from the various State research establishments has issued during the last fifty years an important body of original contributions to the theory of explosives and to the knowledge of their properties.

Metallurgy.—The metallurgical progress of the country has always been a concern of the State by reason of its application to defence by land and sea, and close touch has been maintained with successive developments in the manufacture and use of cast-iron, wrought iron, steel and non-ferrous alloys. While the main advances in process have been made in the great iron and steel works, material contributions to knowledge in this sphere have been made by chemists in the Government service.

Revenue.—For its revenue, imposts were applied in early times, but with great uncertainty, until the charge was put on a scientific basis. Very accurate tables for the strength of alcohol were worked out under the supervision of the Royal Society at the end of the eighteenth century, to be superseded by revised ones issued only a few years ago, when, in addition, new tables were issued also by the Government Laboratory, for determining the gravity of worts before fermentation. The question of rendering alcohol unpotable, but still useful for industrial purposes, has occupied much attention. As some misapprehension still exists as to the availability of alcohol for industrial purposes, a statement has been included in which the main facilities are indicated. It was on account of the necessity for safeguarding the revenue that the Government Laboratory was primarily erected, although it now performs chemical work for all State Departments.

Health.—The three main steps with regard to public health and sanitation in this period were the forcing of these questions into prominence by Playfair, with the consequent Commissions and legislation leading to the formation of the Local Government Board and its successor, the Ministry of Health, which has many varied activities in preserving purity of air and water and protecting the workman in dangerous trades; secondly, the determination of standards for a safe water supply by the pioneering work of Frankland; and thirdly the appointment of public analysts by the local authorities, with the Government Laboratory as referee, for safeguarding the supply of food.

Agriculture.—Science was being applied to agriculture about the end of the eighteenth century, and at the beginning of the next Davy did pioneering chemical work for the Board of Agriculture. Private endeavour is responsible for the next development, State action being limited to the prevention of fraud in the sale of fertilisers and feeding stuffs. In 1909, however, the annual allocation of a sum of money to the Development Commission for the advancement of agriculture stimulated research in a large number of institutions engaged in the scientific study of problems in which chemistry enters.

Other Activities.—In addition to the chemical work reviewed in the foregoing sections, there is a variety of subjects connected with State Departments to which chemists have contributed, such as the composition of the sea, and the composition and physical chemistry of rocks and building-stone. At the Government Laboratory a large number of investigations have been conducted on matters directly referred from Government Departments.

DURING THE WAR

In all the activities described, the war requisitioned the work of the chemist, but, naturally, predominantly to meet the demands of active warfare.

Defence.—The attention that had been bestowed on the subject of propellants enabled expansion to take place with no important alteration in the technique of their manufacture, to which was adapted a new type of cordite, ultimately made on the largest scale, without using an imported solvent. For high explosives we were in much worse case, as these had not been made by the Government, and were manufactured in Great Britain only in small quantity. Their study at Woolwich led to a rapid evolution of new processes, substances, and methods of use. Thus a method was worked out for the manufacture of trinitrotoluene, and to save this substance a new high explosive, amatol, devised. This explosive, consisting of ammonium nitrate and trinitrotoluene, passed exhaustive trials and was ultimately produced at the rate of 4000 tons a week. The production of the ammonium nitrate for the mixture was in itself a stupendous undertaking. In the Research Department, Woolwich, the number of qualified chemists engaged in the study of explosives in all their aspects ultimately exceeded a hundred, while for manufacture and inspection

over a thousand were employed. The ideal set before himself by Lord Moulton in 1914, to produce nothing less than the maximum of explosives of which the country was capable, was realised, and they assumed a quality and character that caused them to be copied by our Allies, and in reliability proved themselves superior to those of the enemy.

Starting unprepared, and without the advantage of a well-developed fine-chemical industry, we were able ultimately to make a reply in the field of chemical warfare that was rapidly becoming more and more effective; at the same time, by study and often self-sacrificing experiment, protecting the soldier by the development of very efficient respirators. In this connexion and in that of explosives nearly every professor of chemistry in the country and many from overseas were engaged.

Metallurgy.—The enormous demand for metals led to an unprecedented concentration of the metallurgical industries on the needs of the State, and to an equal concentration of metallurgical science on investigation devoted to improvement in quality of materials for new and special war purposes. The work of the Aircraft Production Department, aided by many metallurgists and enigneers, on alloy steels, of the National Physical Laboratory on aluminium alloys, and of the Metallurgical Branch of the Research Department, Woolwich, on the heat-treatment of heavy forgings and on the drawing of brass, is typical of the successful effort made in every quarter. The knowledge thus gained was disseminated and has had a great and permanent effect on manufacture.

Health.—A committee of the Royal Society had been studying food values, and were able to afford the Food Controller, when he took office, valuable data bearing on the rationing of food. They had considered subjects which shortly became of much importance, such as a better recovery of flour in milling wheat. The chemical examination of the food for the Army in the war, carried out by the Government Laboratory, employed a large staff of chemists. For the supply of many fine-chemical substitutes used in medicine and surgery, formerly imported from abroad, such provisional arrangements had to be made as the organisation of many university laboratories on a semi-manufacturing basis.

Agriculture.—Effects on agriculture during the war were shortage of the usual feeding stuffs for cattle and of fertilisers. The chemists stationed at Rothamsted gave special attention to the shortage of manures and prepared instructions for the guidance of farmers; and several sources of supply of potash were exploited. As sulphuric acid was required for explosive work, fine grinding of phosphates and basic slag was found to be more efficient than was expected. Shortage also directed the attention of chemists to the use of little known foodstuffs.

Other Activities.—In many other activities in connexion with the war chemists were directly involved, such as in affording advice on the conservation of materials, on the numerous questions arising from the operations of the War Trade Department, on the restriction of imports and exports, and on matters of contraband.

After the War

The magnitude of the chemical effort, it can be claimed, was a factor in winning the war which must be reckoned as of importance only second to that of the bravery of our forces in the field. But it has left a lasting mark, and given to chemistry a value which, were it not for the rapidity with which the achievements of science are forgotten, ought to keep before the public its connexion with almost every phase of activity.

Defence.—To take our subjects in the same order, we may consider some of the effects of the energy spent on the production of munitions. The intensive study of explosives and of other chemical substances used in the war has led to a more complete knowledge of their chemistry, their physical and explosive properties, and has advanced chemical theory. These advantages are not of military importance only, but are reflected in the production of trade explosives, and the records of the Department of Explosives Supply afford examples of treatment of many problems of interest to the general chemical technologist.

A further benefit was reaped by chemists in every position, from the Professor to the youngest graduate, coming into direct contact with manufacturing methods and thus gaining insight into the applications of their science. It became apparent that there was a shortage of a type of chemist which had been developed in Germany, skilled in the transference of the chemical process from the laboratory to the works scale in the largest enterprises. A chemist of this type is one who, besides having a sound knowledge of chemistry and physics, has had experience in the materials of construction used on the large scale and in the operation of the usual types of plant for carrying out the operations of chemical manufacture, and who is capable of working out flow-sheets illustrating the process, and operating plant with every regard to economy. As a result of the war-time experience of our deficiencies in this direction has arisen the movement for erecting Chairs of Chemical Engineering in some of our universities. It is to be expected that from these schools, especially where the instruction is superimposed upon a full graduate course, will emanate men who will lead the way in the application of academic science to industry.

Metallurgy.—While the interest of metallurgical science in war material has fortunately fallen to a peace-time level, State participation in the support of scientific research remains far greater than before the war. In metallurgy it is exercised through the Department of Scientific and Industrial Research, with its organisations of the National Physical Laboratory and the Industrial Research Associations. The State maintains efficient research establishments for the Fighting Services, but it is significant that the largest of these is undertaking industrial metallurgical research on a considerable scale, for the benefit of the brass and other industries. State support and encouragement are undoubtedly powerful factors in the rapid progress now taking place in every branch of metallurgical science in this country, and there is scarcely any related industry which can fail to benefit.

Revenue.—Since the war the principal matters affecting the revenue are the higher duties, which

have rendered necessary a further denaturation of alcohol. Improved facilities have been granted for the use of alcohol for scientific purposes and in industry; regulations have been formulated for the use of power alcohol, and duties have been established on imported fine chemicals and synthetic dyestuffs.

Health.—The food shortage during the war called attention to the nature and quantity of our food supplies, and led to further investigations being undertaken by the Department of Scientific and Industrial Research on food preservation and storage. Committees are also working on the preservatives and colouring matter in food, and on the pollution of rivers by sewage and trade effluents. A great field is open in the co-operation of chemistry with medicine in the discovery of substances suitable for the treatment of the numerous blood parasites.

Agriculture.—So far as fertilisers are concerned, the lack of a supply of fixed nitrogen from the air which obtained throughout the war has now been rectified, and Great Britain for the first time is no longer exceptional among the nations by neglecting to provide itself with synthetic ammonia for agriculture and for munitions. Such war-time expedients as the use of nitre-cake instead of sulphuric acid for making ammonium sulphate and superphosphate and the recovery of potash from flue-dust have not survived, but there has been a gain in the further development of "synthetic farmyard manure" and the increased use of basic slag. The present activity in research in agricultural chemistry of a fundamental character is leading to a better understanding of problems of the soil and of plant and animal nutrition, and cannot fail to be of ultimate benefit to farming.

Organised Applied Research and Assisted General Research.—Established during the war as a result of an appreciation of the contrast between the successful application of scientific method to military purposes and the want of such application to many of our manufactures, the Department of Scientific and Industrial Research has extended over a wide field. Its main activities have been sketched in the directions of State encouragement to industry to apply chemistry to its problems, of State investigation of vital problems beyond the sphere of private enterprise, and of assistance to academic workers.

In the expansion that has occurred in the chemical sections of State Departments since the war, it is interesting to note the increase in the number of chemists that are employed. As far as can be gathered, the number of chemists working in departments maintained wholly by the State is 375 for the present year, compared with 150 in 1912, while in establishments to which the State affords partial support, such as those under the Development Commission and the Research Associations, the corresponding numbers are 150 and 50. In addition, grants are made to 145 research students and to 11 independent research workers, involving a yearly sum of about £50,000.

From the foregoing account of the connexion of the Departments of State in the United Kingdom with chemistry, it is possible to trace a gradual development and ultimately a change in attitude, in passing through the stages of compulsion, expediency, and assistance.

From motives of security the State was compelled to give heed to chemical matters involved in its defence; it was constrained to uphold the standard of its currency; and it was obliged to secure a revenue. As a consequence, the first chemical departments were set up in connexion with these activities, and from them have emanated notable additions to chemical knowledge, improvements in methods of manufacture, and specifications for Government requirements that have led to improved material becoming available for civilian use. Although mostly conducted with inadequate staff, the study of these questions, it can be claimed, proved of national advantage when the time of need arose.

In the next stage, the public conscience having been awakened by the pioneering work of Playfair, it appeared expedient to safeguard health by attention to sanitation, and, as the quality of food was unsatisfactory, to set up a chemical control. Although a start was made by Davy, progress in this subject passed to private enterprise, and a century elapsed before direct assistance was afforded to this important matter. Out of these activities come our present system of supervision over the purity of air, water, and food, and also the recent progress made in investigating problems of the soil.

The last and more recent stage is in the nature of a recognition that the State is under an obligation to assist science, and in this case the science of chemistry, on which so many important industries are based. It took the war to bring home the danger that, although the record of the country as regards discovery in pure science was unrivalled, its systematic application was too often left to other countries, with the result of lamentable shortages during war and the risk of many industries being ineffective in peace. A measure of Government intervention and action appeared requisite, and research became the business of a Government Department. Outside of the great firms which maintain progressive chemical staffs, the firms in numerous industries have been encouraged and assisted to co-operate in the betterment of their manufactures by the application of the methods of science, and from these associations and the organisations dealing with national problems begins to flow a stream of communications indicative of useful work accomplished. Nor is the foundation of it all neglected, for encouragement is given to workers in the academic field to follow out their ideas, whithersoever they may lead them, in accordance with the truth that "research in applied science might lead to reforms, but research in pure science leads to revolutions."

It is important to be able to record an advance in securing an interchange of information among Government Departments, and between their work and that of the universities, a matter which before the war was unsatisfactory, as it was mainly personal and sporadic. And it is a hopeful sign also that, although the knowledge and appreciation of the methods and capabilities of science are still generally wanting, there have been of late signs that these matters are coming to engage the attention of those who guide the policy of the State.

FORTHCOMING EVENTS

Aug. 9. NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS. Annual General Meeting, to be held in the Lecture Theatre of the Institute, Newcastle-on-Tyne, at 2 p.m.

Sept. 4 and 5. IRON AND STEEL INSTITUTE, Autumn Meeting at British Empire Exhibition, at 10.30 a.m. each day. (1) "Changes of Volume of Steels During Heat Treatment," by L. Aitchison and G. R. Woodvine. (2) "Investigations on the Herbert Pendulum Hardness Tester," by C. Benedicks and V. Christiansen. (3) "Effect of Changes in Total Carbon and in the Condition of Carbides on the Specific Resistance and on some Magnetic Properties of Steel," by E. D. Campbell and G. W. Whitney. (4) "Pickling: The Action of Acid on Iron and Steel, and the Diffusion of Hydrogen Through the Metal," by C. A. Edwards. (5) "Examination of Iron from Konarak," by J. N. Friend and W. E. Thorneycroft. (6) "On the Nature of High-Speed Steel," by M. A. Grossman and E. C. Bain. (7) "Improvements in the Brinell Test on Hardened Steel, including a New Method for Producing Hard Steel Balls," by A. Hultgren. (8) "Present Position of the Theories of the Hardening of Steel," by W. Rosenhain. (9) "Effect of Free Surfaces on the Plastic Deformation of Certain Metals," by F. C. Thompson and W. E. W. Millington.

Sept. 8 to 11. INSTITUTE OF METALS. Annual Autumn Meeting, to be opened at the Institution of Mechanical Engineers, when W. M. Corse, S.B., will deliver the third annual Autumn Lecture. On September 9 the morning will be devoted to reading and discussion of papers, followed by luncheon at the Connaught Rooms, Kingsway, the afternoon to be spent at Wembley.

The following papers will be read:—"A Method for Measuring Internal Stress in Brass Tubes," by R. J. Anderson and E. G. Fahlman; "The Application of the Ideal Solubility Curve to the Interpretation of Equilibrium Diagrams in Metal Systems," by D. H. Andrews and Prof. J. Johnston; "Seventh Report of the Corrosion Research Committee of the Institute of Metals," by G. D. Bengough and R. May; "Comparative Results on Copper-Silicon-Aluminium and Other Aluminium Alloys as Obtained on Separately Cast Specimens and Specimens cut from a Crankcase Casting," by E. H. Dix and A. J. Lyon; "The Determination of Sodium in Aluminium," by D. M. Fairlie and G. B. Brook; "The Extrusion of Brass Rod by the Inverted Process," by R. Genders; "Investigation of the Effects of Impurities on Copper. Part II—The Effect of Iron on Copper," by D. Hanson and Grace W. Ford; "The Relationship Between Tensile Strength, Temperature and Cold-Work in Some Pure Metals and Single Solid Solutions," by D. H. Ingall; "On the Effect of Progressive Cold-Rolling on the Brinell Hardness of Copper," by H. Moore; "Experiments on the Working of Nickel for Coinage," by Sir T. K. Rose and J. H. Watson; "Some Experiments on the Effect of Casting Temperature and Heat-Treatment on the Physical Properties of a High-Tin Bronze," by F. W. Rowe; "Some Experiments on the Influence of Casting Temperature and Mass on the Physical Properties of Admiralty Gun-Metal," by F. W. Rowe; "Studies in the Aluminium-Zinc System," by T. Tanabe; "Metal Spraying and Sprayed Metal," by T. H. Turner and W. E. Ballard.

NOTES FROM WEMBLEY

The attractions of the British Empire Exhibition continue in undiminished splendour, and visitors return again and again, ever finding fields and pastures new. Notes on some of the exhibits have been published from time to time in this *Journal*, but how incomplete they have to be! One could fill the whole year's issues of *Chemistry & Industry* and still go on. One would like to linger over the ever-changing stand of the British Dyestuffs Corporation, with its attractive models of plant for making intermediates and dyes, its fascinating array of colour. The giants of alkali industry claim attention, but must be passed; one must neglect the magnificent crystals of various alums on the stand of Peter Spence and Co., Ltd., the attractive blue of copper sulphate shown by James H. Dennis and Co., Ltd.; this time one must resist the attractions of the magnesia exhibit of the Washington Chemical Co.; J. and J. White, Ltd., allure in vain with their fine show of chromium compounds. A detour, to avoid more temptation, and there is Johnson, Matthey and Co., Ltd., with their display of precious metals in such a demure setting, their weights, platinum crucibles, silver nitrate, mercury, so many exhibits that tempt one to write on and on. But across the way an array of pipes calls insistently, and soon one is examining Doulton's exhibit, admiring their acid eggs, elegant in form and finish, their plant for the manufacture of nitric acid, their acid-resisting piping, single, double and treble, their excellent candle filters. There is an interesting vacuum filter on this stand, of earthenware also, but of large capacity and capable of withstanding considerable pressures: it is hoped to return to this filter later. But Doulton's exhibit guards the entry to an array of glassware.

At the stand of Chance Brothers and Co., Ltd., with their 100 years of experience, one expects to be interested, and one is not disappointed. Chemists all know this firm's resistance laboratory glassware, of which there is a goodly assembly, and everyone knows of Chance's sheet glass, coloured glass, rolled glass. There is the optical glass, seen everywhere nowadays ennobled in tortoiseshell, and of which, as of microscope slides and cover glasses, the firm were the pioneer manufacturers in this country. Of special note are "Calorex" glass, which cuts off about 80 per cent. of the heat of the sun, but transmits about 65 per cent. of the light, and "MAXimum" daylight glass, which is a combination of lenses and prisms which collects all available light and distributes it to the best advantage; the industrial utility of two such glasses is very great.

Near by, one can visit Ackroyd and Best, Ltd., of Morley, on whose stand is a series of miners' safety lamps, of which over a quarter of a million are in use. Of excellent mechanical finish, and provided with fittings and accessories (including most ingenious relighters) to ensure safety, easy cleaning, and easy handling, these lamps should be useful in many branches of the chemical industry, as they enable tanks containing explosive gases to be inspected or cleaned in safety. The firm also

makes resistance glassware for laboratory and lighting use and produces automatic tub greasers or oilers that should find application in connexion with conveying and similar plant.

Behind the gas section is the stand of the Thermal Syndicate, Ltd., of Wallsend-on-Tyne, whose exhibit will attract chemical manufacturers as well as chemists. "Vitreosil" pure silica ware, in general use in laboratories, is shown in its various forms, and there are "Vitreosil" basins and balloons for concentrating and distilling acids, carburising boxes for the heat treatment of small pieces, calottes for use in the Kessler plant, a large condensing coil, coolers, pipes and connexions for acid manufacture and large chemical ware for nitric and sulphuric acid and other condensing plants. These large pieces are evidence of the skill with which the difficult technical problems of manufacturing silica ware have been overcome.

In one corner of the Chemical Section is a very interesting stand—a key-industry exhibit. One cannot do justice to this stand, or to the exhibitors, Baird and Tatlock (London), Ltd. Before the writer is a handsome volume of nearly 1000 pages which is labelled "Vol. 1: Chemistry," and describes the firm's products. Three other volumes are devoted to Physiology, Biological Sciences, and Physics, and there are numerous special pamphlets dealing with the analysis and testing of oils, cement and paint, the determination of hydrogen-ion concentration, and other subjects. The stand can be said to be a synopsis of the catalogue, which is divided into sections dealing with laboratory fittings and equipment, furnaces, chemical apparatus, physico-chemical apparatus (measuring, calorimetric, optical, hydrogen ion and electrical), apparatus used in metallurgy and mining and cement testing, organic chemical apparatus including special apparatus for research work, and concludes with a very complete list of chemicals for laboratory work and a general index. The catalogue is a monument and the "B.T.L." stand is a worthy introduction to it. Both must be seen to be appreciated.

SOCIETY OF CHEMICAL INDUSTRY

CHEMICAL INDUSTRY DINNER

It has now been arranged that the Autumn Dinner of the Society, already intimated to be held on November 14, will be a joint function under the auspices of the Society of Chemical Industry and the Chemical Industry Club. The Dinner will be held in the Edward VII. Rooms of the Hotel Victoria, Northumberland Avenue, London, W.C. 2, and will be presided over by Mr. W. J. U. Woolcock, President of the Society. It is hoped that a large number of members of each of the bodies mentioned will, in due course, procure tickets for themselves and their ladies. Full details will be intimated later, but members are asked in the meantime to note the above date and place for the dinner.

CORRESPONDENCE

CHEMOR—THE POLICY RATHER THAN THE FORM

Sir,—There can be no doubt that, as several of your correspondents contend (and some of us illustrate!) we of the chemical profession are in need of either more profound knowledge of the science of language or expert guidance in its use.

If I fully understand Mr. Bousfield's (June 27) answer to my preceding communication (June 20) he is not disposed to press the point that the adoption of the word "chemor" would involve the coinage of a new and unneeded term for the science. I, on my part, am willing to concede that the majority of the words of this class ending in "or" are of Latin origin, direct or indirect (though there are exceptions, such as "sailor"), but I cannot see that that precludes our attaching the same suffix to a root of obscure origin if thereby we get a useful, discriminatory and euphonious word.

Mr. Bousfield points out that the "sister sciences" have practicians (or must it be "practicists"?) designated by words ending in "ist." True, as regards the majority, but must we disown from the family *arithmetic*, *astronomy*, *geometry*, *mathematics*, *philosophy*, and *theology*, because they prefer to give their children names with other endings? In applied sciences may we not even find the termination "or," for instance, in *surveyor* and *navigator*.

Indeed, if the chemist will insist [illegible] the [illegible] exact etymological parallels he wil[illegible] in line, not with his closest relative[illegible] casuist, the dentist and the palmist. I[illegible] will reflect upon the relations betwe[illegible] word[illegible] *art*, *artist*, *artistry*, *artisan*, *artifice*, [illegible] of *artificership*, or will compare *psychiatry*, [illegible] and *psychiatrist* with the corresponding terms ref[illegible]ring to other sciences, he will realise that actu[illegible] language is not as "logical" as if he could "remal[illegible] it to his heart's desire"—by Act of Parliament [illegible] otherwise. Let him even look at his own wor[illegible] "logical" and decide whether he *must* refer to t[illegible] science as "logicianry" or to the scientist a[illegible] "logist."

Furthermore, review of the discussion wil[illegible] that I have not proposed to abolish the [illegible] "chemist" nor even to prohibit its application to the "chemor" as well as the pharmacist. My point is that it is futile to expect the latter to abandon his claim to the word held in common with us, a claim that, as regards both time and province, extends far beyond the authority of the Pharmacy Act of 1869, but that we *can* invent and copyright a new term with the special definition we wish to reserve for ourselves.

If "chemor" is philologically unsound—as to which I remain unconvinced—there are alternatives. Mr. Bousfield's reference to physics is suggestive for the words *physicist* and *physician*, though derived from the same root, are quite distinct in meaning. So also are *artist* and *artisan*. Related to mechanics we have no less than three forms, *mechanic*, *mechanician* and *mechanist*.

"Chemic," though now unused appears once to have been employed as a synonym for alchemist

and might now be revived in a new sense. It is so distinctly obsolete in its old meaning as to carry no objectionable connotation. "Chemician" is the approximate analogue *arithmetician*, *logician*, *mathematician*, *mechanician* and *musician*, and we might also consider "chemicker," which would have the advantage of resembling the German word for chemist.

Conservative minds naturally react against *any* new word. But surely chemists need not be renitent in regard to such a matter. The language is ours. Why not mould it to our purposes?

When Sédillot, reviewing the work of Pasteur, introduced the word "microbe," exception was taken to it on the ground that in Greek *mikrobios* suggested rather short life than minuteness. Littré, though admitting this, nevertheless endorsed Sédillot's choice and advised him "not to trouble to answer criticisms but let the word stand for itself, which it will no doubt do." "As you justly remark," he wrote, "the question is not what is most purely Greek, but what is the use made in our language of the Greek roots." If a French lexicographer could take such a liberal view, why not a British chemist?—I am, Sir, etc.,

J. F. Snell,
Professor of Chemistry

Macdonald College, Que., Canada
July 26, 1924

OBITUARY

SIR GEORGE BEILBY

All those interested in scientific research and its application to industry will hear with great regret of the death, in his seventy-fourth year, of Sir George Beilby, LL.D., F.R.S.

Sir George was the son of G. T. Beilby, M.D., of Edinburgh, and received his scientific training at Edinburgh University. In 1869, at the age of nineteen, he commenced his industrial career with the Oakbank Oil Company. His pioneering work on the manufacture of shale oil is well known and the improvements he effected in collaboration with William Young gave new life to the industry to enable it to compete with imported petroleum oils. After some years of valuable work in this field Sir George turned his attention to new processes for the production of cyanides. In this he was again successful in building up a large and successful company working on his inventions, particularly one relating to the recovery of gold by the cyanide process.

While in Glasgow Sir George took a deep interest in educational matters and for many years was chairman of the governors of the Royal Technical College. In this capacity he was largely responsible for the development of the practical side of scientific training in the College and for enlisting the sympathy and help of other commercial magnates.

Throughout his industrial career Sir George was always interested in fuel economy and in the abatement of the smoke nuisance. His studies of the coal question led, in 1903, to a valuable report to the Royal Commission on Coal Supplies. In 1912–13 he served on the late Lord Fisher's Commission on Fuel and Engines for the Navy and it was his experimental work on which the findings of that committee were very largely based. The committee reported that the only way of securing a home source of fuel oil was to develop a new process for the carbonisation of coal at a much lower temperature than that employed in gas making. A great deal of pioneering work was later carried out under his direction at the Maryhill Works of the Cassel Cyanide Company and became of great value later in the early stages of the experimental work of the Fuel Research Board.

During the war, when the necessity for further work on fuel culminated in the formation of a Fuel Research Board, Sir George was appointed chairman and director. Under his direction the Fuel Research Station at East Greenwich was built and equipped for both laboratory and large scale investigations on the wide schemes adopted by the Government. About the middle of 1923, having placed this great national institution on a sound basis, he retired from active participation. As a consultant, however, he gave advice freely up to within a few days of his death. His last published work, on oil production in the Empire, was presented at the World Power Conference, though his illness prevented his reading it personally.

One important service which he rendered to the community was the institution of the thermal method for charging for town gas, the far-reaching advantages of which have already become apparent.

In the realms of pure science Sir George was always an active worker, and his many papers serve as models of careful scientific observation. His work on the microstructure and physical properties of metals, started as long ago as 1920, culminated some two years ago in a masterly work covering the whole period. His experience in this line of study enabled him to start an illuminating research on the structure of coke, the end of which is not yet in sight.

Sir George was elected a Fellow of the Royal Society in 1906 and received the honour of knighthood in 1916. He had honorary degrees conferred on him by the Universities of Glasgow, Birmingham and Durham. He acted as President of the Society of Chemical Industry (1899), the Institute of Chemistry (1909–12), the Institute of Metals (1916–18) and the Chemical Section of the British Association (1905).

Sir George Beilby was a man of the highest character. He was very reserved and sensitive, but from his friends and from all who came in contact with him in his work he won admiration and affection. His own straightforwardness and honesty of purpose made him severe on quacks, but the trier could always be certain of Sir George's sympathy and help. His death is not only a great loss to science but to all who have been near him in his work.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech.	£23 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	£45 per ton.
Powder	£47 per ton.
Acid Hydrochloric	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers' works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Methylated Spirit 64 o.p.—	
Industrial	3s. 1d.—3s. 5d. per gallon, according to quantity.
Mineralised	4s. 2d.—4s. 6d
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	5¾d. per lb.
Potass. Chlorate	3d.—4d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£3 10s. per ton d/d.
Soda Caustic, solid	Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals	£5 5s—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton, carr. paid.
Sod. Bichromate	4½d. per lb.
Sod. Bisulphite Powder 60/62%	£18—£19 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Sulphide conc. 60/65	About £14 10s. per ton d/d.
Sod. Sulphide cryst.	£9 per ton d/d.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	5¾d.—1s. 4d. per lb., according to quality.
Crimson	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 1d. per lb.
Barytes	£3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide	3s. 9d. per lb.
Carbon Bisulphide	£24—£26 per ton according to quantity.
Carbon Black	7d. per lb. ex wharf. Dearer.
Carbon Tetrachloride	£56 per ton, drums free.
Chromium Oxide, green	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	45s per cwt., barrels free.
Lead Hyposulphite	7½d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£15 10s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Sulphur Chloride	3d. per lb., carboys extra.
Thiocarbanilide	2s. 6d. per lb.
Vermilion, pale or deep	4s. 10d. per lb.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£14 10s. per ton d/d. Demand active.
Grey	£19—£20 per ton. Fair demand.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 per ton, according to grade and locality. Demand below normal.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. „ „ 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 7d. per gall. Unrefined.
Wood Naphtha—	
Miscible	5s. per gall. 60% O.P. Market dull.
Solvent	5s. 6d. per gall. 40% O.P. Fairly good demand.
Wood Tar	£5 per ton.
Brown Sugar of Lead	£46 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	6½d.—6¾d. per lb. Quiet.
Crude 60's	1s. 9d.—1s. 11d. per gall., according to district. Still quiet.
Acid Cresylic, 97/99	2s 1d.—2s. 2d. per gall. Demand still good. Market firm.
Pale 95%	1s. 10d.—1s. 11d. per gall. Quiet.
Dark	1s. 10d.—1s. 11d. per gall. Steady business.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	8d.—9d. per gall. Quiet.
Unstrained	7d.—8d. per gall.
Benzole—	
Crude 65's	10½d.—1s. per gall. ex works in tank wagons.
Standard Motor	1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure	1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.
Toluole—90%	1s. 5½d. per gall.
Pure	1s. 8d.—2s. per gall.
Xylol coml.	2s. 3d. per gall.
Pure	3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	9d.—9½d. per gall. Few inquiries.
Middle Oil, Heavy Oil, Standard Specification	5½d.—6d. per gall in Lancashire 6d.—7d. per gall. in Yorkshire.

Naphtha—	
Solvent 90/160 ..	1s. 1d.—1s. 4d. per gall. according to district. Quiet.
Solvent 90/100 ..	1s. 1d.—1s. 4d. Quiet.
Naphthalene Crude—	
Drained Creosote Salts	£4—£6. Quiet.
Whizzed or hot pressed	£9 per ton. Little business.
Naphthalene—	
Crystals and Flaked ..	£13—£16 per ton in Yorkshire and London respectively.
Pitch, medium soft ..	55s.—60s. per ton f.a.s. for next season. Frequent inquiries.
Pyridine—90/160 ..	17s. 6d. per gall. Market less firm.
Heavy ..	12s.—12s. 6d. Little business.

INTERMEDIATES AND DYES

There has been a fair demand for dyestuffs during the past week. Prices remain constant. A number of intermediate products have been reduced in price.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% ..	1s. 7d. per lb.
Acid H.	4s. per lb 100% basis d/d.
Acid Naphthionic ..	2s. 4d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech. ..	1s. 1d. per lb. Improved demand.
Acid Sulphanilic ..	9½d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	7¾d.—8½d. per lb. naked at works.
Aniline Salts	7¾d.—9d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95% ..	1s. 1d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 19/31° C. ..	4½d. per lb. Demand steady.
m-Cresol 98/100% ..	2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C. ..	2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline	2s. 3d.—2s. 11d. per lb.
Dichloraniline S. Acid ..	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£85 per ton.
Diethylaniline	4s. 6d. per lb. d/d., packages extra, returnable.
Dimethylaniline	2s. 3d. per lb. d/d. Drums extra.
Dinitrobenzene	9d. per lb. naked at works.
Dinitrochlorbenzol ..	£84 10s. per ton d/d.
Dinitrotoluene—48/50° C.	8d.—9d. per lb. naked at works.
66/68° C.	1s. 2d. per lb. naked at works.
Diphenylamine	2s. 10d. per lb. d/d.
Monochlorbenzol ..	£63 per ton.
β Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine ..	1s. 4d. per lb. d/d.
β-Naphthylamine ..	4s. per lb. d/d.
m-Nitraniline	4s. 9d. per lb. d/d.
p-Nitraniline	2s. 3½d. per lb. d/d.
Nitrobenzene	5¼d.—5½d. per lb. naked at works
o-Nitrochlorbenzol ..	2s. per lb. 100% basis d/d.
Nitronaphthalene ..	10½d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis
m-Phenylene Diamine ..	4s. per lb. d/d.
p-Phenylene Diamine ..	10s. 3d. per lb. 100% basis d/d.
R. Salt	2s. 6d. per lb. 100% basis d/d.
Sodium Naphthionate ..	2s. 3d. per lb. 100% basis d/d.
o-Toluidine	8½d. per lb.
p-Toluidine	3s. 3d. per lb. naked at works.
m-Toluylene Diamine ..	4s. 3d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P. ..	£45 per ton.
Acid, Acetyl Salicylic ..	3s. 2d.—3s. 5d. per lb., according to quantity. Good demand. Price firm.
Acid, Benzoic B.P. ..	3s. per lb.
Acid Boric B.P.	Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	19s.—21s. per lb.
Acid, Citric	1s. 5½d.—1s. 6d. per lb., less 5% for ton lots. Market very weak.
Acid, Gallic	3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst ..	6s. 9d. lb. Resublimed quality 8s. per lb. Market firm; increasing demand.
Acid, Salicylic	1s. 6d.—1s. 9d. per lb. Market unsettled and difficult.
Acid, Tannic B.P. ..	3s. per lb. Market quiet.
Acid, Tartaric	1s. 1¼d. per lb. less 5%.
Amidol	9s. per lb. d/d.
Acetanilide	2s. 1d.—2s. 3d. per lb. for quantity. Demand slow.
Amidopyrin	13s. 3d. per lb. Neglected. Stocks low.
Ammon. Benzoate ..	3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate ..	12s. 6d. per oz. for English make.
Barbitone	15s.—15s. 6d. per lb. Quiet market.
Benzonaphthol	5s. 3d. per lb. Small inquiry.
Bismuth Salts	A steady market. Prices according to quantity:
Bismuth Carbonate ..	12s. 9d.—14s. 9d. per lb.
,, Citrate	11s. 4d.—13s. 4d. ,,
,, Salicylate ..	10s. 2d.—12s. 2d. ,,
,, Subnitrate ..	10s. 9d.—12s. 9d. ,,
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides	Unsettled. Spot supplies short. Raw materials dearer. Market advancing. Forward quotations equal to 1s. 3d. lb. for potassium bromide. K.I.D. paid.
Calcium Lactate	Demand active. Good English make can be had from 1s. 7d. to 2s. 6d. per lb.
Chloral Hydrate	4s.—4s. 3d. per lb. Very firm and scarce.
Chloroform	2s. per lb. for cwt. lots. Very steady.
Creosote Carbonate ..	6s. 6d. per lb. Little demand.
Formaldehyde	£52 per ton, ex works. English make in casks.
Glycerophosphates—	Fair business passing.
Calcium, soluble and citrate free	7s. per lb.
Iron	8s. 9d. per lb.
Magnesium	9s. per lb.
Potassium, 50% ..	3s. 6d. per lb.
Sodium, 50%	2s. 6d. ,,
Guaiacol Carbonate ..	10s. 6d.—11s. 3d. per lb.
Hexamine	3s. 6d. per lb. for English make. Market steady.
Homatropine Hydrobromide	30s. per oz.
Hydrastine hydrochlor ..	English make offered, 120s. per oz.
Hypophosphites—	
Calcium	3s. 6d. per lb., for 28-lb. lots.
Potassium	4s. 1d. per lb.
Sodium	4s. ,,
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 5d. per lb., according to quantity.
Magnesium Carbonate—	
Light Commercial ..	£36 per ton net.
Magnesium Oxide—	
Light Commercial ..	£75 per ton, less 2½%.
Heavy Commercial ..	£26 per ton, less 2½%.
Heavy Pure	2s.—2s. 3d. per lb., according to quantity. Steady market.

Menthol—	
A.B.R. recryst. B.P.	53s. 6d. per lb. Market better.
Synthetic	**26s.—35s. per lb., according to quantity. English make. Strong demand.**
Mercurials	Market flat.
Red oxide	5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	**3s. 6d.—3s. 7d. ,,**
White precip.	**4s. 7d.—4s. 8d. ,,**
Calomel	**3s. 11d.—4s. ,,**
Methyl Salicylate	1s. 10d.—2s. 3d. per lb. Keen competition.
Methyl Sulphonal	**26s. per lb.**
Metol	**11s. per lb. British make.**
Paraformaldehyde	2s. 10½d.—3s. per lb. Not very active.
Paraldehyde	1s. 5d.—1s. 6d. per lb. in free bottles and cases.
Phenacetin	6s. per lb. Price and demand steady.
Phenazone	7s. 6d. per lb. A shade firmer. Forward prices higher.
Phenolphthalein	6s. 6d. per lb. Ample supplies.
Potass. Bitartrate— 99/100% (Cream of Tartar)	**88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.**
Potass. Citrate	**1s. 10d.—2s. 2d. per lb.**
Potass. Iodide	**16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues heavy.**
Potass. Metabisulphite	**7½d. per lb., 1-cwt. kegs included.**
Potass. Permanganate	6½d. per lb. Keen competition keeps price low.
Quinine Sulphate	**2s. 3d. per oz., in 100 oz. tins. Very heavy demand.**
Resorcin	5s. 6d.—5s. 9d. per lb.
Saccharin	**63s. per lb., in 50-lb. lots.**
Salol	**3s. 6d.—3s. 11d. per lb.**
Silver proteinate	**9s. 6d. per lb.**
Sod. Benzoate, B.P.	2s. 6d. per lb. Ample supplies. B.P. quality available.
Sod. Citrate, B.P.C., 1923	**1s. 11d.—2s. 2d. per lb., according to quantity.**
Sod. Hyposulphite— Photographic	**£13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.**
Sod. Metabisulphite cryst.	**37s. 6d.—60s. per cwt. nett cash, according to quantity.**
Sod. Nitroprusside	**16s. per lb. Less for quantity.**
Sod. Potass. Tartrate (Rochelle Salt)	**75s.—82s. 6d. per cwt., according to quantity. Steady market, good demand.**
Sod. Salicylate	**Market more active. Powder 2s. 2d.—2s. 4d. per lb. Crystal at 2s. 4d.—2s. 6d. per lb. Flake 2s. 9d. per lb.**
Sod. Sulphide— Pure recryst.	**10d.—1s. 2d. per lb., according to quantity.**
Sod. Sulphite, anhydrous	**£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.**
Sulphonal	15s. 6d. per lb. Easier.
Thymol	19s. per lb. Very scarce indeed. Still rising.

PERFUMERY CHEMICALS

Acetophenone	**12s. 6d. per lb.**	
Aubepine	**15s. 3d. ,,**	
Amyl Acetate	**2s. 9d. ,,**	
Amyl Butyrate	**6s. 9d. ,,**	
Amyl Salicylate	3s. ,,	Cheaper.
Anethol (M.P. 21/22° C.)	**4s. 6d. ,,**	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	**2s. 10½d. ,,**	
Benzyl Alcohol free from Chlorine	**2s. 10½d. ,,**	
Benzaldehyde free from Chlorine	**3s. 6d. ,,**	
Benzyl Benzoate	**3s. 6d. ,,**	
Cinnamic Aldehyde Natural	16s. ,,	
Coumarin	**20s. ,,**	
Citronellol	17s. ,,	
Citral	9s. Price reduction due to selling competition.	
Ethyl Cinnamate	13s. 6d. ,,	
Ethyl Phthalate	**3s. 3d. ,,**	
Eugenol	**11s. ,,**	
Geraniol (Palmarosa)	**35s. ,,**	
Geraniol	**11s.—18s. 6d. per lb.**	
Heliotropine	7s. 9d. ,,	
Iso Eugenol	**15s. 9d. ,,**	
Linalol ex Bois de Rose	**26s. ,,**	
Linalyl Acetate	**26s. ,,**	
Methyl Anthranilate	**9s. 6d. ,,**	
Methyl Benzoate	**6s. ,,**	
Musk Ambrette	**45s. ,,**	
Musk Xylol	14s. ,,	
Nerolin	**4s. 9d. ,,**	
Phenyl Ethyl Acetate	15s. ,,	
Phenyl Ethyl Alcohol	**16s. ,,**	
Rhodinol	**57s. 6d. ,,**	
Safrol	**1s. 10d. ,,**	
Terpineol	**2s. 4d. ,,**	
Vanillin	26s. per lb.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	**15s. 6d. per lb.**
Anise Oil	**2s. 8d. per lb.**
Bergamot Oil	18s. per lb. Cheaper.
Bourbon Geranium Oil	**36s. 6d. ,,**
Camphor Oil	**75s. per cwt.**
Cananga Oil Java	**10s. 6d. per lb.**
Cinnamon Oil, Leaf	**6½d. per oz.**
Cassia Oil, 80/85%	**8s. 9d. per lb.**
Citronella Oil—	
Java 85/90%	5s. 8d. per lb.
Ceylon	3s. 7d. per lb.
Clove Oil	7s. 6d. per lb. Firm.
Eucalyptus Oil 70/75%	2s. 1d. per lb. Fair business.
Lavender Oil—	
French 38/40% Esters	30s. per lb. Very firm. Higher price expected owing to bad crops.
Lemon Oil	3s. per lb.
Lemongrass Oil	3d. per oz.
Orange Oil, Sweet	13s. per lb.
Otto of Rose Oil—	
Bulgarian	37s. 6d. per oz. Production below average.
Anatolian	18s. per oz.
Palma Rosa Oil	**19s. per lb.**
Peppermint Oil—	
Wayne County	21s. per lb. Firm spot and forward.
Japanese	14s. 3d. per lb.
Petitgrain Oil	9s. 3d. per lb.
Sandal Wood Oil—	
Mysore	**26s. 6d. per lb.**
Australian	**21s. per lb.**

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition not later than October 14th, they are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on August 28th.

I.—Applications

Carrier Engineering Corporation. Refrigerating systems. 18,316. July 31. (U.S., 7.8.23.)

Lodge-Cottrell, Ltd. (Metallbank und Metallurgische Ges.). Electrodes for electrical precipitation of suspended particles from gaseous fluids. 18,026 and 18,091. July 28 and 29.

Moseley. Process for oxidising etc. materials. 18,366. Aug. 1.

Wayne Tank and Pump Co. Filtering apparatus. 18,182. July 30. (U.S., 4.4.24.)

I.—Complete Specifications Accepted

5309 (1923). Somerville and Williams. Adsorbent materials and the manufacture and application thereof. (219,352.)

10,264 (1923). Pike. Method and apparatus for producing calcining and clinkering material. (219,369.)

10,800 (1923). Drew and Laidlaw. Means for generating steam and combustion products under pressure for power purposes. (219,377.)

11,457 (1923). Erickson. Filters. (219,413.)

30,063 (1923). Lodge-Cottrell, Ltd. (Metallbank und Metallurgische Ges. A.-G.). Apparatus for the electrical precipitation of suspended particles of gaseous fluids. (219,570.)

2220 (1924). Kantny. Apparatus for liquefying and separating gases. (219,599.)

II.—Applications

Anglo-Persian Oil Co., Ltd., and O'Brien. Refining mineral oils etc. 18,424. Aug. 1.

Barker, and Bernsford. Apparatus for separating coal from dirt etc. 17,924. July 28.

Du Boistesselin. Process for agglomerating coal dust etc. 18,101. July 29. (Fr., 29.9.23.)

Duckham, Finlayson, Smith, and Woodhall Duckham (1920), Ltd. Operating vertical retorts for carbonising fuel. 18,478. Aug. 1.

Milner and Munroe. 18,212. *See* XIXA.

Moeller. Treating peat etc. 18,482. Aug. 2.

Oil Development Trust, Ltd. Hydrocarbon containing material. 17,992. July 28.

VOL. 43 NEW SERIES | LONDON, AUGUST 22, 1924 | NO. 34

EDITORIAL

WE publish this week a characteristic contribution from Prof. H. E. Armstrong dealing with Prof. Bancroft's recent paper on the action of metals on nitric acid. It does not deal exclusively with this topic, others find their way spontaneously into the argument. After reading the article we were reminded, somewhat illogically, of a saying quoted in Boswell's "Johnson": "*Qu'il y a d'esprit! Il y a tant, répondit Mme. de Bourdonne, que je n'y ai pas vu de corps.*" Prof. Armstrong's universal plodding has not prisoned up his nimble spirits in his arteries; he retains some slight disapprobation of modern ionic views of chemistry, which he can ne'er express, yet cannot all conceal. When we say he can ne'er express it, we mean only that he cannot express it so definitively and so forcibly that it can be done once and for all. Just as formaldehyde is reputed to have a cumulative effect, so he believes that these small, almost innocuous doses of criticism will gradually destroy the pernicious influences and will keep alive a spark of genuine chemistry, which though now overladen by dull ashes of positive and negative signs, will some day blaze forth and illuminate the surrounding atmosphere. It is almost time that he kneeled down—not humbly—on his knees, and with distended lungs and cheeks blew the spark into a flame. We have a very hazy idea how in the ordinary households they managed to keep their home-fires burning before the days of matches; of course, they had tinder-boxes at one period, but the making of sparks and their conversion into flames must have been a laborious business, and it is obvious from the old poets that it was a calamity to let a wood fire so die out that it had to be relighted. We think it is Homer who speaks of preserving the spark in ashes so as to avoid a long journey to a distant neighbour in search of something to start a new fire. And what a business it must have been to transport it for a distance; the fashion of drinking tea and coffee could not have spread as it has done in damp climates but for the lucifer match! We appeal to Prof. Armstrong to shed the elusive and gentle poetry with which he envelops his views, to discard the metaphor and allusion which permeate his arguments and to give us his notions on metals and nitric acid in plain chemical words, whose rugged simplicity will enable even editors to understand them. Let him attack the Ionians in harsh Doric, and leave the soft Lydian airs to a more effeminate body of readers!

* * *

The conclusion of an agreement of some sort between Germany, France, Britain and several other countries is a matter of considerable interest to all industrial chemists. The particular agreement made a few days ago is considered by public men in this country as an achievement much to the credit of Mr. Ramsay MacDonald and the Government of which he is the chief. He has shown himself to be possessed of tact and patience; everyone was tired of the state of European politics which we had endured so long and the time was ripe for an alteration. Even so, a less capable man might easily have bungled the matter and left the situation in a dangerous state. The details of the agreement are difficult to understand and easy to criticise, but the spectators cannot follow the forces at work, the attractions and reactions, and they are bound in such matters to assume, not that the agreement is the one most suited to European politics, but that it is the best which is possible to persuade the parties to agree to. This is a vital distinction which is frequently forgotten: in our editorial wisdom we could easily have solved the problems of Reparations and the Ruhr, the Covent Garden strike or any other strike, and have persuaded the Bankers to lie down with the Bolsheviks; our only difficulty was that we could not have persuaded the parties most concerned to fall in with our solutions. Mr. Ramsay MacDonald and the Foreign Office have done well; but there are many other difficulties to be overcome before any satisfactory course of action will develop. In the manufacture of certain articles Germany will be a better customer than competitor; in the manufacture of many chemical compounds Germany may easily be a competitor to be feared and an insignificant customer.

There are economical problems of singular importance to be faced; there are, especially in Germany, some political dangers of great moment. European trade has been thrown out of gear by the War; the most essential requirements of good trade, credit, confidence and stability, are lacking and it will take two or three years to establish these; everything is abnormal and unstable, the mark, the franc and the pound have no permanent relation to each other; a new equilibrium has to be established and we have all to become gradually accustomed to the new conditions whatever they are before trade can be in a healthy state again. Credit, confidence and stability are of slow growth; no nationalisation, no artificial treatment of national debts, no direct action of strikers, no revolutionary ideas can take their place. The agreement with Germany is to be welcomed to the extent to which it encourages credit, confidence and stability; probably this will be a very considerable extent, but it is too early to judge.

* * *

This week we publish for the first time a paper contributed to the Institution of Chemical Engineers. We are glad to do this and we hope that in the future the Transactions of the Institution will be as important and interesting as this one, a contribution by Professor Hinchley and Mr. Himus on "The Effect of a Current of Air on the rate of Evaporation of Water below the Boiling Point." The paper gives the result of about two hundred and fifty experiments and it appears that these were carefully carried out on a logical and scientific plan. The rate of evaporation of water in a pan over the top of which there is a current of air seems to be directly proportional to the difference between the vapour pressure of the water in the pan and the vapour pressure of water in the air. There is a definite rate of evaporation when there is no current of air, and between this limit and a speed of current of five inches per second the increase in rate of evaporation is approximately proportional to the speed of the current. The data are given with a degree of accuracy sufficient for many operations conducted on a large scale, and the various graphs are convenient for reference. The only experiments of this nature we have ourselves conducted, blowing a current of air over a hot cup of tea in a railway refreshment room, have invariably been so hurriedly carried out that accurate determinations have been practically impossible, even on those rare occasions when time permitted a completion of the experiment. We think plants exposed to much wind, especially very dry winds, have in some instances developed special devices for preventing an undue loss of water. The evaporation of liquids on a large scale, either in vacuo or at the normal pressure of the air, is now so common an occurrence that a careful study of the conditions is essential. The authors of the paper call attention to the scanty literature on this subject. An investigation on the lines they have adopted involves much time and attention, and what is more it involves some little thinking, so the paucity of literature is not surprising.

THE EFFECT OF A CURRENT OF AIR ON THE RATE OF EVAPORATION OF WATER BELOW THE BOILING POINT.*

By G. W. HIMUS, B.Sc., A.R.C.S., D.I.C. (Associate-Member), and J. W. HINCHLEY, A.R.S.M., F.I.C., Wh.Sc. (Member)

At a conference of the Chemical Engineering Group of the Society of Chemical Industry held in Glasgow in 1922, one of the authors discussed the subject of evaporation in general and put forward certain tentative formulæ. Systematic research in this subject has been planned for work in the new Chemical Engineering Laboratories of the Imperial College of Science and Technology. This paper is the first submitted, and deals in more detail with certain aspects of evaporation of water in currents of air.

It is a matter of regret that the so-called educational economy of the last few years has withheld a large proportion of the sum voted for the equipment of those laboratories. The apparatus with which this work was done was, in consequence, inadequate, but it is hoped that more sympathetic treatment may enable us in the near future to carry on the work with more satisfaction. We thought it better, however, to present the paper as it is, rather than to wait for the future when more refinements could be added to the apparatus.

To the chemical engineer, a knowledge of the rate of evaporation, and the ability to estimate that rate from a knowledge of the physical properties of the substances in hand, and the atmospheric and other conditions obtaining in the plant is a matter of considerable moment. Not only is the design of crystallising and drying plant directly dependent on such knowledge, but evaporation plays a by no means unimportant part in the working of cooling towers and other plant.

In spite of, or perhaps, because of the frequency with which such problems arise for solution, the literature of the subject is meagre. Investigation of an index of scientific and technical papers reveals the fact that information relevant to the point at present under discussion is relatively small. Of papers on evaporators and on their design and operation, there is no end. The meteorologist seems to be well supplied with information on the subject, while the hydraulic engineer, the agriculturist and the physiologist are also catered for. The chemical engineer, however, can find but little help, as the work either deals with evaporation as applied to a specific type of plant, or else is almost entirely mathematical, and in some cases seems to be devoid of experimental backing. Furthermore, in general, the conclusions of the mathematical analyses of the problem are apt to be couched in such form that they cannot be applied to practical problems. The paper concerns itself with evaporation from water surfaces at different temperatures under varying conditions of draught.

* Read at the Second Annual Meeting of the Institution of Chemical Engineers, July 16, 1924.

Experimental.

The evaporating pans used were made of sheet copper, all being of the same depth, viz., three inches, and supplied with heating coils of Ni-chrome wire, carried on half-inch silica tubes set along the lengths of the pans about a quarter of an inch from the bottom.

Four pans were employed, 3 in. × 12 in., 6 in. × 12 in., 12 in. × 12 in. and 6 in. × 18 in., the first with one, the second with two, and the third with four heating coils. The 6 in. × 18 in. pan had two coils only. The heaters in the 3 in. × 12 in., and the 6 in. × 12 in., were wound with 105 turns of wire in each; in the foot square pan, the inner coils had 105 and the outer 130 turns, while those in the 6 in. × 12 in. pan carried 150 turns.

A duct through which a current of air could be blown over the evaporating pan in use was provided. This duct was made in four sections of galvanised iron, each section being 2 ft. long, three of them 9 in. high by 1 ft. 6 in. wide. The remaining section, in one end of which was the fan creating the draught, was 18 in. square at the fan end and tapered to the same section as the other three sections. The end of the duct remote from the fan was left open. The photograph (Fig. 1) gives a general view of the apparatus.

Fig. 1

The section of the duct below which the pan was placed was provided with a window 1 ft. square in the roof, and one in each side 1 ft. by 6 in. In the bottom a hole was cut which sufficed to admit entrance of the upper edge of the evaporating pan, the remainder of the open space round the pan being closed by pieces of galvanised iron.

The draught was created by means of a fan driven by belt and pulley from a motor, means of adjustment of the speed within fairly narrow limits being provided by an external resistance. In order to obtain greater limits of variation of draught, a series of driving pulleys from about 4 in. to 18 in. in diameter was furnished.

The temperature of the water in the pan was determined by means of a mercury thermometer hung from a wire across the duct, the tubes containing the heating elements being covered by 40-mesh copper gauze bent into the shape of inverted U's—this to cause better distribution of convection currents in the water.

In several experiments the temperature at different points of water was taken, but was found to be substantially the same throughout, the difference from point to point being of the order of half a degree.

The evaporating pan when in use was carried on one pan of a balance, so arranged that the upper edge of the pan was just above the level of the bottom of the duct.

The general method of conducting the experiments was as follows:—

(a) The temperature of the water in the pan was brought to the desired point by regulation of the heater-current and was maintained steady or very nearly so. During this preliminary period the draught was on, the speed of the air-current being determined by means of a fan-type anemometer placed at the open end of the duct on the middle line thereof.

(b) The conditions having become steady, the pan of water was rapidly counterpoised, a stop-watch was started and the temperature of the water was noted.

(c) A known weight was then placed alongside the pan of water, the magnitude of the weight depending on the rate of evaporation, and the apparatus was observed, the time being noted when the balance again stood level. The temperature of the water was then taken again.

(d) Another weight was then placed alongside the pan, and the time taken for equilibrium to be established was noted. This was repeated a number of times, till a suitable weight of water had been evaporated.

(e) The amount of water evaporated in one experiment depended on the conditions, falling as low as twelve grammes in the case of the smallest pan without draught, and rising to as much as six to eight hundred grammes in the case of the largest pan. The accuracy of weighing was in the neighbourhood of 0·02 grammes.

(f) The dew point of the air of the laboratory was taken by means of a Hinchley hygrometer at least once during each experiment, and the barometer was read periodically.

(g) The results were calculated to kilogrammes of water evaporated per square metre of surface per hour, and for each pan and each draught these rates were plotted against the difference between the vapour pressures of the water at the temperature of that in the pan, and at the dew point observed during the experiment.

(h) About two hundred and fifty experiments in all were carried out, a small number of these being in still air, these latter to test the validity of the formula published for evaporation in still air by Hinchley (*J.S.C.I.*, 1922, xli, 242 T).

FIG. 5

(i) The details of a single experiment which serves to indicate the general run of the observations may be given :—

No. 121. Pan area ½ sq. foot (6 in. × 12 in.), draught transverse to pan. Barometer 758 mm. Correction factor to 760 mm., 0·998.

Time. Min. sec.	Water Temp. °C.	Loss in Weight.	Dew Point. °C.	Air Temp. °C.	Draught.
0	79·0	—	1·1	3	4·17
4 55	79·0	100	—	3	metres
9 55	79·0	100	—	3·2	per
14 55	78·6	100	—	3·2	second
	78·9	300	1·1	3·1	

Rate of evaporation, 26·0 kilos per square metre per hour.
corrected, 26·95 „ „ „ „ „ „
Vapour pressure water in pan .. .. .. 338 mm.
„ „ „ „ air .. .. .. 5 mm.
Difference .. .. 333 mm.
Rate of evaporation of water per 1 mm. difference = 0·078 kilos per square metre per hour.

(j) It will be observed that a correction has been made to the observed rate of evaporation for the deviation from 760 mm. of the barometer. This is in accordance with the correction indicated by Hinchley in the paper quoted above.

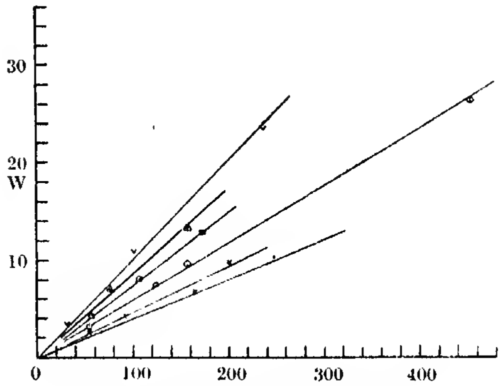
Throughout the following, the symbols used are as follows :—

W is the rate of evaporation in kilos per square metre per hour corrected to a barometric pressure of 760 mm.

p_e is the vapour pressure of the water in the pan in mm. of mercury.

p_a is the vapour pressure of the water in the air in the same units.

v is the velocity of draught in metres per second.



Evaporation in 12 in. square pan.

v Draught 5·70 metres per second.

Fig. 7

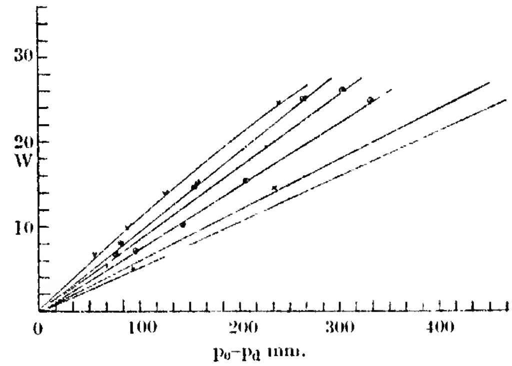
Results and Conclusions

(1) The Imperial College formula for evaporation of water in still air was found to hold good, viz.,

$$W=\left(\frac{p_e - p_a}{50}\right)^{1\cdot2}$$

(2) Over a range of draughts from 0·9 metres per second, and with water temperatures of from 20° to 70° C., the rate of evaporation is found to be, for practical purposes, in accordance with the law $W=a(p_e-p_a)$, where a is a coefficient varying only with the draught, and is equal to $0{\cdot}031+0{\cdot}0135$ v.

(3) Figures 2 to 9 show the experimental results plotted against a (p_e—p_a) basis, the rates being obtained at a number of fixed draughts in each pan. It is seen that the plots are substantially



Evaporation in 6 in. × 1 ft. 6 in. pan on right side of duct.

v Draught 5·78 metres per second.

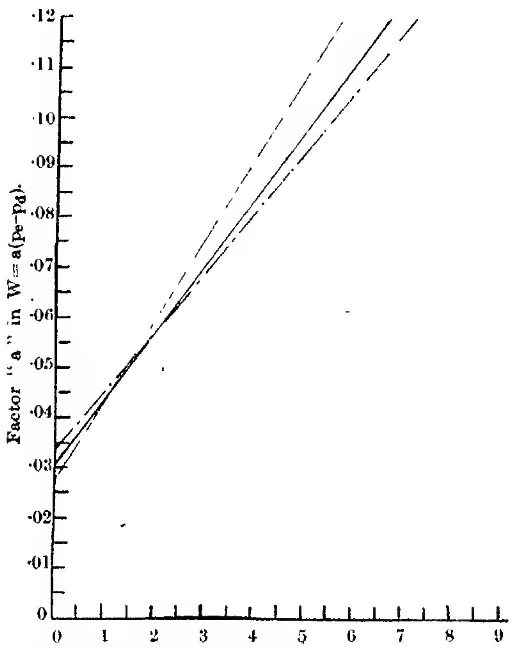
Fig. 9

straight lines, although at temperatures of over about 60° C., particularly with the larger pans, there is a deviation from the straight-line law. Such deviation may be ascribed to the fact that under these conditions the mean value of the dew point,

and therefore of p_d over the surface of the pan, may vary considerably from that of the air of the laboratory. The errors resulting from the assumption that the straight-line law holds good, will, however, under practical conditions of working, seldom exceed five per cent., as in drying-room practice, the temperatures and velocities will seldom rise as high as those of a number of the experiments in which these faults are apparent.

(4) The individual formulæ for the various pans studied are :-

3 in. × 12 in. pan, transverse draught	$W = (\cdot 028 + \cdot 016\ v)(p_e - p_d)$
Ditto, longitudinal draught ..	$W = (\cdot 030 + \cdot 013\ v)(p_e - p_d)$
6 in. × 12 in. pan, transverse draught	$W = (\cdot 034 + \cdot 012\ v)(p_e - p_d)$
Ditto, longitudinal draught ..	$W = (\cdot 031 + \cdot 016\ v)(p_e - p_d)$
12 in. × 12 in. pan	$W = (\cdot 027 + \cdot 012\ v)(p_e - p_d)$
6 in. × 18 in. pan	$W = (\cdot 034 + \cdot 012\ v)(p_e - p_d)$
Mean for all pans	$W = (\cdot 031 + \cdot 0135\ v)(p_e - p_d)$



Showing variation with draught of factor "a" in $W = a(p_e - p_d)$.
—·—·— Average all pans.

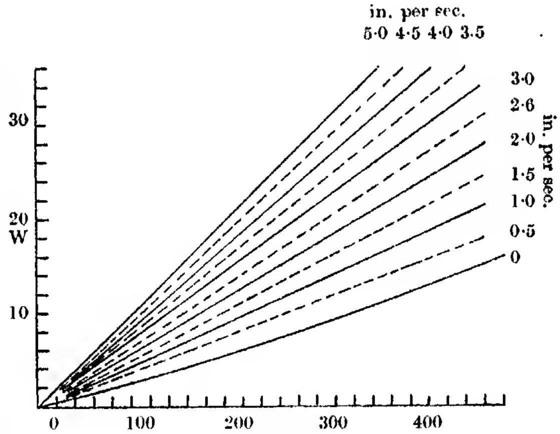
———— 6 in. pan. Transverse draught.

Draught. Metres per second.

Fig. 10

(5) It will be observed that, according to the formulæ above, in still air, the rate of evaporation should be directly proportional to the vapour pressure difference, whereas, in the absence of draught, it is found that the rate is proportional to this difference to the power of 1·2. This probably arises from the fact that in the absence of draught, the air over the pan will be in motion due to convection currents, the magnitude and effect of these currents rising with the temperature. It will be recalled that a similar case is met with in the formula for loss of heat from surfaces due to air contact: instead of the temperature difference, we have the temperature difference to the power of 1·23.

(6) According to the above formulæ, preheating of the inlet air to the duct should have no effect on the rate of evaporation, provided that the air be not heated to such a temperature that transfer of heat from it to the water surface takes place. This conclusion has not yet been experimentally verified.



Rates of evaporation calculated for various draughts, plotted against $(p_e - p_d)$. Formula $W = (\cdot 031 + \cdot 0135v)(p_e - p_d)$.
"No-draught" line is calculated from $W = \{[\cdot 02(p_e - p_d)]\}^{1.2}$
W = Kilos. of water per sq. m. per hour.

Fig. 11

(7) It will be noticed that in the formulæ for the individual pans, the "no draught" and the "draught" constants vary, the former from 0·016 to 0·012, and the latter from 0·027 to 0·034. Furthermore, this variation is not regular, and seems to bear no relation to the size of pan. Despite careful checking of the work, it has not been found possible to account for this, but it is suggested that this may be caused, in part, at any rate, by the fact that the draught was inclined somewhat to the axis of the duct, the result being that the distribution of the draught relative to the water surface must have been different in different pans; in other words, the vertical component of the velocity varied in the different pans. A knowledge of the intensity of the draught at various points over the water surface would probably clear up this point, but apparatus for determining this satisfactorily was not to hand.

(8) Figure 10 shows the variation of the factor "a" in $W = a\ (p_e - p_d)$ with draught, (*a*) the average of all the pans, (*b*) the 3 in. and (*c*) the 6 in. pan with transverse draught.

(9) On figure 11 is plotted a series of graphs showing the rates of evaporation calculated from the general equation arrived at from the experiments,

against vapour pressure difference. It will be noted that the calculated draught evaporations are far above the no-draught results from the Imperial College formula, up to a vapour-pressure difference of 480 mm. and with draughts from 0·5 to 4·0 metres per second. The question, whether, at lower draughts than those plotted, the straight line law will give place to some law intermediate between the draught and no-draught formulæ could not be solved practically, owing to the difficulty of determining such very low draughts, but it seems obvious that the change from the curve to the straight line may occur when the vertical component due to turbulence becomes greater than that due to convections.

(10) The formula indicates that in the case of water solutions for which Raoult's law holds, the rate of evaporation may be evaluated accurately from a knowledge of the vapour pressure depression. This has not been tested in the present investigation, but passing mention may be made of the fact that the Imperial College formula for still air evaporation is found to apply to the evaporation of solutions of glycerine.

(11) Carrier (quoted by Hinchley in paper above) gives a formula for rate of evaporation, which, in metric units, is $W = 0{\cdot}0178\ (1+v/1{\cdot}17)\ (p_e - p_d)$.

The present formula if transposed into the same form becomes $W = 0{\cdot}031\ (1+v/2{\cdot}29)\ (p_o - p_d)$.

According to the Carrier formula, the rate of evaporation in a draught of 1·17 metres per second is double that in still air for the same vapour pressure difference, whereas the present formula shows that the effect of draught is almost exactly half this.

In the absence of knowledge of the exact apparatus and means by which Carrier determined his figures, it is not possible to suggest any definite explanation of the discrepancy.

(12) While admitting that the present formula is by no means an exact expression of the relation of the rate of evaporation to the physical conditions, it is hoped that the conclusions embodied in the present paper may find use amongst chemical engineers who have to solve evaporation problems.

Edge Effect.—The experiments suggest that an edge effect exists (*i.e.*, that a proportion of the area is protected from the currents of air at the edges of the pan), but that it was very small.

Vibration and Ripples.—At a point when ripples began to be definitely produced an increased evaporation was apparent. Vibration of the apparatus produced a similar result. At the higher velocities ripples were always in evidence.

Effect of the Dimensions of the Duct.—This effect has not been well investigated, but at high velocities and temperatures there could be no question of the effect on the curves.

Further Experiments.—Owing to the fact that p_d changes somewhat during the passage over the surface, and with a view to reducing this to small dimensions, a narrow pan was made (1 in. × 12 in.). The results with this pan were more irregular, the departure from the straight line appeared to be greater, and the velocity factor was higher.

Use of the Formula.—It is hardly necessary but it may be desirable to indicate how the formula may be applied in the design of evaporators and dryers. Having assumed the standard conditions at the inlet and outlet of the air, the rates of evaporation at these points may be estimated. The logarithmic mean of these results will give the average rate of evaporation throughout the plant and indicate the area of surface required for the conditions assumed.

We wish to thank The Sturtevant Engineering Co., Limited, for the gift of a large portion of the apparatus.

WHY WAS I BORN SO SOON?

(With acknowledgments to Bernard Shaw)

By HENRY E. ARMSTRONG

" If Science was what Science seems,
And not the Science of our dreams,
How much we'd hate her—
But she ain't "
—*Kipling* (*revised*).

Some may well reply—" Why at all ? A more confounded nuisance never was. Worse than any kid, with his perpetual ' whys ' and heuretic twaddle. We agree with the Dauphin and dislike being consecrated with his rancid oil, let alone made to fight. Damn his Joan'ian ' voices,' urging us to think ; we want to be let alone, not worried to answer absurd riddles. We are happy in our ionised 'ell and don't wish for even a day off ; it has been made quite comfy by Sir James Dewar and Prince Conti, not to mention the saintly trinity, Arrhenius, Nernst and Ostwald, who have taught us to disregard water and chop logic with equanimity."

This by way of Shavian preface. When a riddle is posed, sometimes someone says—" Ask another," so let me follow such precedent and modestly ask—Is Wilder D. Bancroft a beaten-fraud and have I, all my life, been a born fool and the whole world chemical

a body of wiseacres; or is perhaps the leg in the other boot? Unless Bancroft and I *are* rank rotters, the mind chemical *is* in a peculiar state of suspended animation, needing some catalyst to awaken it from its long-continued condition of catalepsy. This, however, is no mere riddle but a serious problem in psychology—the psychology of the crowd sciential. We chemists think we are awfully fine fellows, whether or no we can roll a pill, superior to the vulgar herd—but it is to be feared that our 'superbity,' however much it may be Nobel'ised, has no reasoned foundation; not only "from the stalls and in the Press is an atmosphere of hypocrisy spread" but also from the lecture desk and the text-book.

Why do I bring the slim Bancroft upon the stage in such connexion, in connexion with myself? Why this outburst of spleen? The exciting cause is a long disquisition, entitled *Action of Metals on Nitric Acid*, by the said Wilder D., in the May issue of the *Journal of Physical Chemistry*, a copy of which he has most obligingly sent to me. I shall ask that it be buried or burnt with me. The opening sentence is significant:—

> "For nearly thirty years, I have carried the reduction of nitric acid by metals in my note-books as a major problem to be taken up as soon as possible and, at different times during that period, I have suggested it to graduate students as a desirable thesis subject—all in vain."

What the state of those note-books must be, exposed as they have been so long to the influence of so corrosive an acid, can be imagined, if we think of the youthful Ira Remsen's early experiment, when he placed a copper coin upon his father's bare mahogany and poured upon it a few drops of Aquafortis. As he says, the miraculous effect, not only upon the copper and the mahogany but upon his fingers and trousers and the carpet, was startling and one that he never forgot. Bancroft's soul, however, like that of the multitude, seems not to have been easily seared by the acid and, until this year, note-books notwithstanding, he has displayed no fiercely burning curiosity to explain its marvellous behaviour. Like the world chemical, he has had eyes to see, nay more, he assures us, he has desired to see; yet he has not seen; I will not use the language of Thermodynamics and say, which is absurd! but simply remark—that the ways of the workers in science are mysterious. Have I assisted in his conversion? Last year, in Cambridge, England, I cast my gauge at him and challenged him to consider the facts of chemical change in general *from an electrolytic standpoint.* He did not then accept battle but said—"he would go home and read." Apparently, he has not only read but also marked, learnt and inwardly digested, quite a little and in a way which would be flattering to my vanity had I any such element left in me. After telling us what the great Ostwald believed in 1899; that Mellor is distinctly non-committal but inclines to Ostwald; that Roscoe and Schorlemmer dodge the whole question (Chorus of Chemists: "And so do all of us"); the gospel according to Veley; how Howe plays safe with a vengeance—he refers to the work done by a former City firm, that of Acworth and Armstrong, at a time which is prehistoric to the pedagogues of to-day, the year of our gracious Lord one thousand eight hundred and seventy seven. After quoting with approval their statement:—

> "We regard the action of the metal as consisting simply in the displacement of the hydrogen of the acid,"

he adds the following, showing how his soul, like John Brown's, has gradually been marching on towards a state of sanity and understanding:—

> "This is, of course, a special statement of the electrolytic theory of corrosion, long before it was developed as a general theory by Whitney in 1903. A few years later, I pointed out that the most striking characteristic of an electrolytic action is that it occurs in two places—at the anode and at the cathode. This peculiarity can be made less marked by bringing the electrodes nearer and nearer together. When the distance between them vanishes, we have a chemical reaction in the ordinary sense of the word and not an electrochemical reaction. Any chemical reaction, therefore, which can be made to take place electrolytically, must consist of an anode and a cathode process. Considering the matter in this light, we see that there is a possibility of the anode and cathode processes interfering and of one perhaps masking the other."

The general results of the discussion are summarised in ten paragraphs, the first being:—

> "The action of nitric acid on metals can be considered profitably as a case of electrolytic corrosion, the anode reaction being the formation of the nitrate. This is the view advocated by Armstrong in 1877."

The second is:—

> "The nature of the metal shows itself in at least three ways; in the reducing power as measured by over-voltage; in the catalytic action of the metal; and in the catalytic action of the salt of the metal. These three factors are to be studied in detail"

It is not for me to say that the first is good—it is the issue to be disputed. The second, entirely Snarkian as it is, may be alright but seems to make confusion worse confounded, being compounded of fuming, furious, otherwise frumious, words, without any defined, accepted meaning (compare *Journal of General and Industrial Chemistry*, July, p. 763).

However, I have a sort-of-a-kind of Rip-van Winklish, Wellsian Sarnac (the Dream) feeling on thus being woken up, though after only forty-seven years, to find myself dubbed a prophet, with evidence before me that a logical idea can be got into a present-day chemist's mind: the probability of ever penetrating its thick cuticle had seemed too remote. It is fortunate my rescuer from a wilderness of oblivion should be the Giant Wilder, who publicly ranks, with Brutus, as an honourable man; his words, therefore, may well be adsorbed by the hitherto earless multitude. Granted poetic license, my grati-

tude could not be better expressed than in the Omarian lines :—

"A Book of Verses underneath the Bough,
A Jug of Wine, a Loaf of Bread—and Thou
Beside me singing in the Wilderness—
Oh, Wilderness were Paradise enow."

Provided the jug were big enough,* we might discuss Aquafortis to a finish and preach confusion to the many.

I feel that I owe an abject apology to Bancroft for my entirely previous behaviour. In extenuation, I can only plead that I was subject to much evil electrolytic communication in my early youth, not the least being, that in 1870 I happened into the position formerly held by Grove of gas-battery and "Grove-battery" fame. Often, with my own hands, I had to set up 50 Grove cells for use with a Duboscq projection-lantern and so sucked my fill of nitrous fumes and gained not only respect for the depolariser but began to ask myself what its function was.

Everything conspired then to my electrical 'temptation.' A set of Faraday's Researches was knocked down to me, at Stevens' Auction Rooms, together with one of Frankland's zinc ethyl digesters.

Still, it is a horrible thought, as marking our rate of progress, that my son, already a Past-President of the Society of Chemical Industry, has not been taught by his text-books to know what I knew before his synthesis was even begun. He will shortly visit Cornell (I venture no geographical indication of its location) and will, I trust, return from its tents imbued with a reasoned faith and carrying the message of a revised *entente chimique* from one to the other shore, so near but yet so far, of the great salted pond he will cross.

Smee, the inventor of the Smee cell, was one of my bosses; De la Rue another; he and Hugo Müller were at work, close at hand, at their silver chloride non-polarisable cell. To-day, no chemical student has anything to do with an electric-battery: poor soul, electrons are just fed to him from a wire, as food is to the Strasburg geese. Like the mechanic, he is being reduced to watching a machine, instead of doing things with his own hands. In my early youth I acquired a nasty way of myself burrowing for answers to some of the "Whys?" that came into my mind. Later on, Paley's Evidences and the Law Courts infused elementary notions of logic into my composition, at the same time making me suspect of all argument. My downfall was completed by compiling an introductory text-book of Organic Chemistry, the only branch of chemistry with logic in it and some sense of proportion. I may be pardoned mentioning these details but it is well to make clear that light—may be darkness in my case—only comes with pain and tribulation, through experience, not a degree-course. It is written :—

"One's feelings lose poetic flow,
Soon after twenty-seven or so."

This may be true of poetry but not of chemistry: the chemist only begins about that age to reflect and be worth his salt. Indeed, my faith was not declared and complete until 1885, when I adopted $C = \frac{E}{R}$ as my motto and not only sought to evaluate E but asserted that chemical change only took place when (at least) a three-component system was constituted: I could then safely predict that a mixture of hydrogen and oxygen would be found to be inexplosive. I already, at that date, put aside the Arrhenius speculation as without foundation in fact, taking particular objection to the absurd distinction drawn by the school between the two hydrides, HCl and H_2O. Hofmann, twenty years before, had taught me to appreciate their substantial identity in behaviour—but he *was* a chemist, with regard for facts.

Unfortunately, to-day chemists are not like boys—they will not be chemists: they elect, like sheep, to go astray. Their leaders are described to a T in *Lycidas*, particularly as interpreted by Ruskin in *Sesame* and *Lilies*, a book to be studied in preference to any chemical text-book.

The method of our schools—the product of our vile examination system, which makes both *Lehr* and *Lernfreiheit* impossible—is that of the turned-up trousers hem, not that of Zadig as expounded by Huxley in his incisive essay. The situation has been described before to-day :—

"Professionizing moral men

. . . . .

The poems bought in youth they read
And say them over like their creed,
All autumn crops of rhyme seem strange;
Their intellect resents the change."

Perhaps in 1932, even Bancroft will assert the absurdity of the Arrhenic faith and will be accepted of men. Last, will come, not merely the recognition of her beauty but of the almighty power as a chemical agent, when duly married, of fair Hydrone. Then, my shade will have to apologise for my horribly previous behaviour: I shall take care to leave him with a fully executed power of attorney.

Physicists are indulging in the highest flights of imagination as to the electronic structure of atoms, while chemists have no consistent theory of the commonest interchanges of molecules—of chemical change in general. Our backwardness in framing a comprehensive theory is a disgrace to our cloth. What happens to a metal in nitric acid matters little—what does matter is the fact, that the souls of our young chemists are being filched from them by the present race of teachers, who are but foisting dogma upon them; "blind mouths," indeed, withholding from their pupils the art and power of thinking for themselves, of thinking logically and with regard for truth. The present ways of education lead directly to the devil and dullness. No other conclusion is possible, if Bancroft be indeed a Daniel come to judgment, a credible witness.

* We have it from the Knight of Yadil, that wine was appropriately served to him in New York in a bedroom jug—as a natural detergent.

Then, tear him to pieces, ye tribe of idolators, if ye can; if ye cannot, repent ye of your ways, cast down your ikons, think what ye are doing and let others think.

Cory clearly foresaw our situation in writing :—

"Fair ladies, by your leave,
I would exhort you, spin and weave
Some frugal, homely cloth.
I warn you when I lead the tribes,
Law shall strip you; threats nor bribes
Shall blunt the just man's wrath."

NOTES FROM WEMBLEY

It is related that after Dickens had visited the "Great Exhibition" he wrote to a friend: "It is a dreadful thing to be obliged to be false, but when anybody says: 'Have you seen so-and-so?' I say 'Yes,' because if I didn't, I know he would explain it, and I can't bear that. . . ." Readers of the notes on the British Empire Exhibition that have been published from time to time in *Chemistry and Industry* may or may not feel with Dickens, but it cannot but be a general experience that so many "so-and-so's" are yet to be seen that visits have to be multiplied.

Lack of space last week prevented mention of an interesting exhibit on the stand of Messrs. Baird and Tatlock (London), Ltd., in the Chemical Section. The exhibit, due to Messrs. Ridsdale and Co., of Middlesbrough, illustrates the British chemical standards movement and the "Analoid" system of analysis. There is no need to emphasize the importance of accurate analysis for chemical research, but when a sample, say, of ore, is examined by several chemists, the need for standard methods is not always realised. Messrs. Ridsdale show nearly ninety standardised samples, and these are used widely at home and abroad, nearly 50,000 g. having been supplied in the eight years of existence of the movement. With every portion of standard, a certificate is supplied showing the co-operators, and the method and results of each analyst and the average result. The value of such standards is incontestable whether for chemist, manufacturer, buyer or engineer, and it is interesting that the movement is voluntary, the co-operators giving both service and material. The "Analoid" system of analysis is a standardised method for steel, iron and slag, the object being to minimise variable factors, and to obtain results more quickly, cheaply and simply.

One must be particularly tall to watch the dough go in and biscuits come out of the working bakery exhibited by Messrs. Baker, Perkins, Co., so thick is the crowd, and so unwilling is it to move. The smooth working of the plant is, indeed, fascinating, and gives reason to surmise that all the chemical plant made by this engineering firm at Peterborough is equally well-designed.

An interesting visit can be paid to the stand of Messrs. G. and T. Weir, Ltd., Glasgow, in the Palace of Engineering, whether to their display of pumps or to the smaller stand devoted to Monel metal and nickel. Specimens are shown illustrating the many uses of monel metal due to its resistance to alkalis, hot gases, most acids, saline solutions, extremes of temperature, corrosion and abrasion. All the ordinary operations of machining, welding, casting, polishing, etc., can be applied to the metal, which is used in making wire screens for paper mills, textile plants, glue manufacture, alkali works and gas works, as sheeting for hydro extractors, centrifugal dryers, dye vats, and in the form of bolts used in soap and alkali works. Its resistance to high temperatures and fire action has led to its use in glass furnaces, superheaters, valves and furnace stay bars, and it is particularly suitable for making pump impellers which must withstand the action of hot liquids at high velocity. In the chemical industry monel metal is finding wide application, and its freedom from tarnish is an additional recommendation wherever appearance is important.

Allen West and Co., Ltd., a firm which specialises in the manufacture of motor control apparatus, shows a large and comprehensive range of gear for the control of motors of all sizes, from small industrial machines to the large motors used on colliery winders and haulages. Oil-immersed, iron-clad, totally enclosed switchgear is shown as a 5-panel board and also separate units. The switchgear consists of a 375 amp. type "SM" circuit breaker for the incoming unit in the centre of the board, having a triple-pole isolating switch, and trifurcating box. A patent safety interlocking device is fitted, which prevents the removal of either the oil tank or cover while the isolating switch is on. It also prevents the closing of the isolating switch if either the oil tank or cover is removed. The break has a free handle and consequently cannot be held closed on an overload. On the left of the incoming panel is a type "SM" star delta starter, and a type "SM" auto transformer starter. The design of these starters is similar to the main incoming circuit breaker unit; they are used for starting up squirrel-cage induction motors. On the extreme right of the board is a type "SRI" combined stator and rotor starter, for starting up slipring induction motors; this is suitable for motors up to 30 h.p. It comprises a 3-pole contactor switch for the stator circuit with overload trips, the contactor operating coils acting as a no-volt release, and a multi-contact face-plate switch, with quick step-to-step motion, for cutting resistance out of the rotor circuit. Both the stator and rotor switches with the resistance are housed in the one case, whereby a very compact unit is obtained. The operation is by one handwheel only, and the stator switch cannot be kept closed on an overload or failure of voltage. This oil immersed switchgear is also shown made up for use in fiery mines and other places where the air is laden with dangerous fumes. Another interesting exhibit, also representing the latest practice, is the complete equipment for controlling a four motor crane. Other exhibits such as the complete equipment for controlling a 1500 h.p. winder motor, air break drum controllers, of the ordinary industrial type, for use in collieries, stamped steel resistances, lifting magnets, or special insulating material, are worthy of close inspection.

FORTHCOMING EVENTS

Sept. 4 and 5. **Iron and Steel Institute**, Autumn Meeting at British Empire Exhibition, at 10.30 a.m. each day. (1) "Changes of Volume of Steels During Heat Treatment," by L. Aitchison and G. R. Woodvine. (2) "Investigations on the Herbert Pendulum Hardness Tester," by C. Benedicks and V. Christiansen. (3) "Effect of Changes in Total Carbon and in the Condition of Carbides on the Specific Resistance and on some Magnetic Properties of Steel," by E. D. Campbell and G. W. Whitney. (4) "Pickling: The Action of Acid on Iron and Steel, and the Diffusion of Hydrogen Through the Metal," by C. A. Edwards. (5) "Examination of Iron from Konarak," by J. N. Friend and W. E. Thornoycroft. (6) "On the Nature of High-Speed Steel," by M. A. Grossman and E. C. Bain. (7) "Improvements in the Brinell Test on Hardened Steel, including a New Method for Producing Hard Steel Balls," by A. Hultgren. (8) "Present Position of the Theories of the Hardoning of Steel," by W. Rosenhain. (9) "Effect of Free Surfaces on the Plastic Doformation of Certain Motals," by F. C. Thompson and W. E. W. Millington.

Sept. 8 to 11. **Institute of Metals.** Annual Autumn Meeting, to be opened at the Institution of Mechanical Engineers, when W. M. Corse, S.B., will deliver the third annual Autumn Lecture. On September 9 the morning will be devoted to reading and discussion of papers, followed by luncheon at the Connaught Rooms, Kingsway, the afternoon to be spent at Wembley.

The following papers will be read:—"A Method for Measuring Internal Stress in Brass Tubes," by R. J. Anderson and E. G. Fahlman; "The Application of the Ideal Solubility Curve to the Interpretation of Equilibrium Diagrams in Metal Systems," by D. H. Andrews and Prof. J. Johnston; "Seventh Report of the Corrosion Research Committee of the Institute of Metals," by G. D. Bengough and R. May; "Comparative Results on Copper-Silicon-Aluminium and Other Aluminium Alloys as Obtained on Separately Cast Specimens and Specimens cut from a Crankcase Casting," by E. H. Dix and A. J. Lyon; "The Determination of Sodium in Aluminium," by D. M. Fairlie and G. B. Brook; "The Extrusion of Brass Rod by the Inverted Process," by R. Genders; "Investigation of the Effects of Impurities on Copper. Part II—The Effect of Iron on Copper," by D. Hanson and Grace W. Ford; "The Relationship Between Tensile Strength, Temperature and Cold-Work in Some Pure Metals and Single Solid Solutions," by D. H. Ingall; "On the Effect of Progressive Cold-Rolling on the Brinell Hardness of Copper," by H. Moore; "Experiments on the Working of Nickel for Coinage," by Sir T. K. Rose and J. H. Watson; "Some Experiments on the Effect of Casting Temperature and Heat-Treatment on the Physical Properties of a High-Tin Bronze," by F. W. Rowe; "Some Experiments on the Influence of Casting Temperature and Mass on the Physical Properties of Admiralty Gun-Metal," by F. W. Rowe; "Studies in the Aluminium-Zinc System," by T. Tanabe; "Metal Spraying and Sprayed Metal," by T. H. Turner and W. E. Ballard.

Sept. 15. **British Empire Exhibition.** Conferences of Engineering Societies, to be held in Conference Hall No. 4, at 10.30 a.m. Short papers on various Engineering Subjects will be read and discussed.

SOCIETY OF CHEMICAL INDUSTRY

CHEMICAL INDUSTRY DINNER

It has now been arranged that the Autumn Dinner of the Society, already intimated to be held on November 14, will be a joint function under the auspices of the Society of Chemical Industry and the Chemical Industry Club. The Dinner will be held in the Edward VII Rooms of the Hotel Victoria, Northumberland Avenue, London, W.C. 2, and will be presided over by Mr. W. J. U. Woolcock, C.B.E., President of the Society.

It is hoped that a large number of members of each of the bodies mentioned will, in due course, procure tickets for themselves and their ladies. A circular letter with further particulars and a form of application for tickets will be issued early in September, but members are asked in the meantime to note the above date and place for the dinner.

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

The price of Volume VIII (1923) to members of the Society is 7s. 6d., and to non-members 12s. 6d., post free in each case.

Fellows of the Chemical Society have the privilege of purchasing the volume at the price of 10s. post free.

A set of Volumes II to VIII inclusive can be purchased by a member of the Society at the price of £2 2s 6d., and by a non-member at the price of £3 15s., post free in each case.

CHEMICAL SOCIETY'S ANNUAL REPORTS

The Council of the Chemical Society has decided to increase the price of future issues of the Annual Reports on the Progress of Chemistry, and the volume for 1924 (XXI) which will be issued next year will be sold to the public at 10s. 6d., plus postage. To members of the Society of Chemical Industry will be given the privilege of purchasing the volume at 9s., post free. Orders, accompanied by the appropriate remittance, should be sent to the Assistant Secretary, Chemical Society, Burlington House, London, W. 1, before the end of the present year.

DEATHS

Beilby, Sir George T., F.R.S. (Original Member), of 29, Kidderpore Avenue, Hampstead, London, N.W. 3, Former President of the Society. On August 1, 1924.

Berk, Frederick W. (elected 1893), of 1, Fenchurch Avenue, London, E.C., Chemical Manufacturer. On June 23, 1924.

Biggart, William L. (elected 1891), of 29, Catherine Street, Greenock, Public Analyst. On March 14, 1924.

Dobbie, Sir James J., F.R.S. (Original Member), of Fairlie Cottage, Fairlie, Ayrshire, late Government Chemist. On June 19, 1924.

Earp, William R. (Original Member), of Preston Brook, near Warrington, Chemical Manufacturer. On July 25, 1924.

Farrington, T. (Original Member), of 4, Waterloo Place, Cork, Ireland, Chemical Engineer. On May 2, 1924.

Lorleberg, Charles (elected 1909), of Messrs. R. W. Greeff and Co., Thames House, Queen Street Place, London, E.C., Director. On June 11, 1924.

ACADÉMIE DES SCIENCES

On June 23 M. Rateau communicated a paper by M. Dumanois, showing that tetraethyl lead used in aviation engines to prevent "knocking" enabled the volumetric degree of compression to be raised from 5 to 9. M. Mesnager communicated a paper by M. de Fleury on the use of light alloys for the pistons of internal-combustion engines, showing that it is not the thin piston but the piston which is sufficiently thick that is required in light metal. M. Lindet recorded that M. Hethe has obtained the glyceride myristine from milk fat by direct crystallisation in ether. He also stated that, according to M. Saillard, this year the molasses would contain more raffinose than in preceding years, and that this sugar seemed to form in the beets at the end of the season and during storage.

On July 16 M. Schloesing presented a note by MM. Hein and Andubert on the agglutination and coagulation of rubber latex, the object being to define the agglutinating and coagulating power of various agents so that the rubber could be classified and compared. Prof. Moureu described some work on the radio-activity of hot springs in Madagascar and Reunion. In general the gases of the springs are feebly radio-active, but the dissolved radium is present in double the usual quantity and in one spring thorium emanation was identified. It is known that the injection of serum from another species of animal may cause poisoning. In a paper presented by Dr. Roux, MM. Lumiere and Couturier showed that sera lose their toxic power when held in a vacuum, a conclusion which suggests that carbonic acid plays an important part. In fact, on subjecting sera detoxicated in a vacuum to the action of carbonic acid under pressure the sera recovered their toxicity. The conclusion was that the toxicity of normal sera was due to the physical state of the flocculate, the form of which depends on a labile fixation of carbonic acid on certain amido groups of the proteins, or on other elements present.

On July 21 Prof. Haller described work on the essential oil of the iris by MM. Langlais and Goby, who have isolated from it, in addition to irone, a series of fatty acids including caprylic, pelargonic, capric, lauric and other acids. M. G. Bertrand described researches tending to show that zinc is a growth factor for organisms in which it exists in small quantities. Dr. Roux described a gravimetric method, due to M. Fosse, for estimating cyanamide.

The following chemistry prizes have been awarded: Prix Montyon des Arts Insalubres, divided between M. B. André (2500 f.) and M. Lazennec; Prix Lacage (10,000 f.), for the best work on chemistry, to Prof. C. Matignon; Prix Jecker (10,000 f.), for progress in organic chemistry, to Prof. Simon, of the Natural History Museum; Prix Houzeau, to M. Chevenard; and the Fondation Cahours (3000 f.) to Mlle. S. Weil.

On July 28 Dr. Roux communicated a paper by N. M. Fernbach and Stoleru showing that the antiseptic power of hops was only shown in culture media having a sufficient hydrogen-ion concentration. This observation is of practical interest to the brewer, as it shows that the quantity of expensive hops necessary could be reduced by increasing the acidity, which in addition assists to stabilise the beer and aids the preservative action of the hops.

Prof. Moureu described the result of work by M. Job on the catalytic activation of ethylene by organo-metallic compounds, and also announced that Prof. Matignon had obtained oxalic acid from carbon monoxide and potassium carbonate heated to 470° C. under a pressure of 243 atmospheres.

On August 4 Dr. Roux discussed the conclusions arrived at by M. J. Regnier on the variation of the anæsthetic power of a solution of cocaine chlorhydrate as a function of the hydrogen-ion concentration. The anæsthetic power depends on the reaction of the solution; if this is alkaline, anæsthesia is more rapid and lasts longer.

THE FRENCH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

The annual meeting of this association has just been held at Liège (Belgium), under the presidency of M. Viala. The chemical section, presided over by M. Huybrechts, had a number of interesting papers. M. Lance described the substitution of carbon monoxide (produced in an auxiliary generator) for metallurgical coke in the blast-furnace, the object being to reduce the consumption of coke and to produce by-products such as liquid hydrocarbons and hydrogen. Prof. Grignard and M. Stratford discussed the cracking of petroleum. M. J. Pougnet described the action of ultra-violet rays and considered the allotropic modifications of bodies in false equilibrium, and M. Meunier showed that gaseous mixtures which react violently, *e.g.*, hydrogen and oxygen, methane and air, do not react when brought into contact with flame unless the proportion of the constituents of the mixture was confined within certain limits. Synthetic resins and their uses were discussed by M. G. Kimpflin.

From biological observations made with M. Mangin, M. Viala explained there was documentary evidence that the scale insect ("Phthiriose"), which caused great damage to the vine in Palestine, lived at the time of the Hebrews on the aerial parts of the vine. The scale insect, which is extremely sensitive to variations in atmospheric moisture, lives to-day, however, solely on the roots, thus showing the change in the climate of Palestine since biblical times. To aid its resistance against drought the scale insect lives in association with a fungus which grows around the wound made in the vine by the insect, over which it forms a protective covering.

NITROGEN FIXATION IN FRANCE

The National Industrial Office for Nitrogen recently established in France has been attached to the Directorate of Hydraulic Power, under the Ministry of Public Works.

CORRESPONDENCE

"METHANOL"

Sir,—The Federation of Swedish Chemical Industries hereby begs to draw your attention upon the following :—

Methyl alcohol has, as it is known, in many different countries caused and still causes a lot of poisoning cases. Especially in its pure state, the smell and the taste of methyl alcohol is so like the smell and the taste of ethyl alcohol, that a confusion can happen very easily. Already the denomination methyl *alcohol* may give rise to the supposition that one has to do with an article which eventually may be used as a substitute for ethyl alcohol and thus is good for drinking. Besides this a slightly indistinct or damaged label may cause a confusion. Certain countries have already become aware of the danger this implies and changed the name methyl alcohol to *methanol*, by which one may consider the most important cause of confusion as eliminated. The National Wood Alcohol Association has introduced the name methanol in the U.S.A. In Germany just as in England it has been partly adopted, for instance by the firm of E. Merck in Darmstadt. "Methanol" is no new denomination; it was introduced in 1892 at the International Nomenclature Congress in Geneva.

In Sweden, on account of the restrictions for selling of alcoholic drinks and their high prices, the abuse of substitutes of all kinds, including also methyl alcohol, has been rather frequent. It has even been proposed to dye the methyl alcohol in order to prevent confusion with ethyl alcohol. In order to preclude difficulties which may arise in the trade of methyl alcohol, as well as on account of the above mentioned social reasons, the Federation of Swedish Chemical Industries considers it to be its duty to recommend the adoption of the term *methanol*. The principal thing is that this is done in practice, *i.e.*, that the article bears the proposed denomination *everywhere* where non-experts are handling it, as for instance in manufactures, warehouses, during transport, etc.

All interested parties, producers as well as users, have declared themselves for the change of the name. Some of the former, besides, expressed the desire that the Federation of Swedish Chemical Industries should inform foreign professional circles about the change. Even the Swedish authorities and unions, *e.g.*, the Royal Swedish State Department of Health, the Royal Administration of the Swedish State Railway and the Pharmaceutical Society have declared that they will adopt the new denomination *methanol* which thus soon will be generally used in Sweden.

As the same reasons as in Sweden probably exist also in your country the Federation of Swedish Chemical Industries takes the liberty to inform your Society about this change and begs to ask you kindly to communicate it to the interested circles and contribute to the general adoption of the denomination *methanol* by publishing the above in your *Journal*.

Our association is addressing a similar communication to the respective unions in other countries.—
I am, Sir, etc., OTTO LEGIÉUR,
Sveriges Kemiska Industrikontor Federation of Swedish Chemical Industries
Stockholm, August 15, 1924

OPTICAL ACTIVITY AND POLARITY THEORIES

Sir,—An attempt has recently been made to relate the magnitude of the molecular rotation of an optically active substance to the "polarity" of the groups attached to the asymmetric atom (H. G. Rule, *J.C.S.*, 1924, **125**, 1121). It is claimed that, in general, "the replacement of a hydrogen atom in an optically active compound by a positive substituent displaces the rotation in the opposite sense to that due to a negative substituent, and that the magnitude of the displacement corresponds more or less closely to the position of the substituent in the polar series, so far as this can be judged from the limited data at our disposal."

The suggestion is an interesting one. Unfortunately, however, the meaning of the term "polarity," when applied to a group of atoms in a chemical compound, is not free from obscurity. Dr. Flürscheim (*J.C.S.*, 1909, **95**, 718), by comparing the strengths of substituted benzoic acids with that of benzoic acid $\left(\text{k polar} = \frac{\text{k meta} + \text{k para}}{2\ \text{k benzoic acid}}\right)$ deduced the following electropolar series: $-NH_2$, $-CH_3$, $-H$, $-OH$, $-Cl$, $-NO_2$; in which $-NH_2$ is regarded as a strongly positive group and $-NO_2$ as strongly negative.

Flürscheim's classification of these groups appears to have been generally accepted. Thus Prof. Robinson (Annual Reports of Chem. Soc., 1922, p. 98) writes that "the groups $-CH_3$, $-H$, $-Cl$, $-NO_2$ represent a descending series in regard to the electropositive character of the constituent atoms," and he explains the relative influence of these groups upon the case of hydrolysis of substituted benzyl chlorides as an example of *general polar effect*. The introduction of the $-CH_3$ group is supposed to render the molecule more electropositive and therefore more easily hydrolysed, whilst the introduction of the chlorine atom or $-NO_2$ group renders the molecule less electropositive and therefore less easily hydrolysed.

Flürscheim's view has also been endorsed by Prof. Lapworth. "There appear to be, for example, (*a*) general polar effects, certain atoms tending to raise or lower the affinity of the molecule as a whole for an electric charge." (Lapworth and Shoesmith, *J.C.S.*, 1922, **121**, 1392.)

On the other hand, according to the theory of induced alternate polarities, although the $-CH_3$ group must be regarded as positive in its *general* polar influence, the C-atom in this group is *negative* from induced polarity, $-\overset{-}{C}\overset{+}{H}_3$. In a similar manner the N-atom in the negative $-NO_2$ group has an *induced positive* polarity $-\overset{+}{N}\begin{smallmatrix}\nearrow O \\ \searrow \overset{-}{O}\end{smallmatrix}$. It would appear, therefore,

that the $-NO_2$ group may be described either as highly negative or as highly positive according as one happens to be thinking of its general polar influence or of its induced alternate polar influence. This circumstance renders the interpretation of the meaning of the phrase "polarity of groups" somewhat difficult.

From the introductory paragraphs of Mr. Rule's paper, in which he speaks of the work of Vorländer, Flürscheim, and Michael having "*prepared the way for the theory of induced alternate polarity put forward by Lapworth*," one draws the conclusion that when Mr. Rule refers to the "polarity" of a group attached to an asymmetric atom he is thinking of the induced polar influence of this group and not of its general polar effect. This impression is strengthened by a consideration of the order in which Mr. Rule places his groups: $-OH$, $-Cl$, $-CH_3$, $-H$, $-CO_2H$, $-CN$, $-NO_2$. This sequence, as Mr. Rule explains, can be arrived at by an examination of benzene substitution data.

On the other hand, Mr. Rule's statement that the very similar series: $-Cl$, $-OH$, $-CH_3$, $-H$, $-CO_2H$, $-CN$, $-NO_2$, can be deduced from "the influence of various groups on the dissociation constants of substituted acetic (or benzoic) acids" is a surprising one. For it is a familiar fact that chloroacetic acid resembles cyanoacetic acid in being stronger than the unsubstituted acetic acid; and that the three chlorobenzoic acids, like the three nitrobenzoic acids, all have higher dissociation constants than benzoic acid. In these cases the *general* polar effect evidently predominates over any other influences which may be at work. In other words, the effectiveness of the group in increasing the strength of the acid is in agreement with its position in Flürscheim's electropolar series: $-NO_2$, $-Cl$, $-OH$, $-H$, $-CH_3$, $-NH_2$, rather than with its position in the induced polar series: $-NO_2$, $-CN$, $-H$, $-CH_3$, $-Cl$, $-OH$.

Mr. Rule makes the further claim that the series $-NO_2$, $-CN$, $-H$, $-CH_3$, $-Cl$, $-OH$, can be deduced from the inductive capacities of compounds of the types C_2H_5X and C_6H_5X. But since, according to the data quoted by Mr. Rule, the influence of these groups upon the inductive capacities is in the order $NO_2 > CN > Cl > CH_3 > H$ it is not easy to see how this claim can be justified.

The first of the examples by which Mr. Rule illustrates his hypothesis of the relation between optical activity and the "polarity of groups" attached to the asymmetric atom is a series of derivatives of lævo-rotatory amyl alcohol.

($R = C_4H_9$)	$[M]_D$
$R.\ CH_2\cdot OH$	$-5\cdot19$
$R.\ CH_2\cdot NH_2$	$-5\cdot10$
$R.\ CH_2\cdot Cl$	$+1\cdot81$
$R.\ CH_2\cdot C_2H_5$	$+6\cdot23$
$R.\ CO\cdot OH$	$+18\cdot21$
$R.\ CH_2\cdot CO\cdot OH$	$+10\cdot35$

With regard to this series Mr. Rule remarks "it will thus be seen that $-CO_2H$, the only positive group contained in the list, stands at one extreme with the highly negative hydroxyl group at the other." As Mr. Rule here speaks of the $-CO_2H$ group as positive, it is natural to assume that he is considering its induced alternate polar influence.

Writing the series again from this point of view, we have

$R\cdot\overset{+}{C}H_2\cdot\overset{-}{O}H$	$-5\cdot19$
$R\cdot\overset{+}{C}H_2\cdot\overset{-}{N}H_2$	$-5\cdot10$
$R\cdot\overset{+}{C}H_2\overset{-}{Cl}$	$+1\cdot81$
$R\cdot\overset{+}{C}\overset{-}{O}\cdot\overset{-}{O}H$	$+18\cdot21$
$R\cdot\overset{-}{C}H_2\cdot\overset{+}{C}O\cdot OH$	$+10\cdot35$

It will be observed that in all cases, except the last, the group R is in combination with *positive* carbon. From the point of view of the theory of induced alternate polarities, $-CO_2H$ is thus by no means "the only positive group contained in the list." On the other hand, $-CH_2\cdot CO_2H$ may, in the language of the theory, be described as the only negative group which is directly combined with the radical R. If, therefore, there were any relationship between the molecular rotation of a compound and the induced polar effect of a substituting group, one would anticipate a change in the sign of the rotation, on passing from $R\cdot\overset{+}{C}\overset{-}{O}\cdot\overset{-}{O}H$ to $R\cdot\overset{-}{C}H_2\cdot\overset{+}{C}O\cdot OH$. No change of this character is observed and hence one may conclude that the magnitude of the rotation is not dependent upon the *induced* polar effect of the substituting group.

It is equally difficult to trace any relationship between the magnitude of the rotation and the *general* polar effect of the substituting groups. It would seem, therefore, that when Mr. Rule speaks of a relationship between optical activity and the "polarity of groups" he is attaching to the word polarity a meaning different from either of the meanings hitherto commonly associated with the word.—I am, Sir, etc.,

"COAL AND POWER"

The Neglect of Science

Sir,—The publication of "Coal and Power," Hodder and Stoughton Ltd., price 1s. nett, which we are informed is the "Report of an Inquiry presided over by the Right Hon. D. Lloyd George," and has the approval of Mr. Asquith, is rather interesting to the chemist and the chemical engineer. The press is already full of articles on the question, mostly written by politicians and other people whose knowledge of the subject is limited to their gleanings from the Encyclopædia Britannica, and the episode is only another reminder that it is time the average chemist woke up.

If we do not have the actual control as well as the publicity, not only of coal and power but of many other subjects vested in the technical man, whether he be, in the broad sense of the word, engineer, chemical engineer, or chemist, instead of the politician, the lawyer, the accountant and similar people, we are bound to come a crash. The

state of the colliery industry has given us sufficient warning for years past, and the iron and steel industries are drifting more and more to a serious crisis. The real reasons are very largely lack of scientific methods, including the neglect of the trained technical man, and the almost entire absence in industry until the last year or two of the co-operative spirit.

It is, of course, easy to laugh at "Coal and Power" from a scientific point of view—and any technical journalist could have written the "power" section as part of his daily work—but at any rate it shows the terrible conditions under which many of the miners are compelled to live, and the chaos in the industry due to mining royalties, high railway rates, and all kinds of circumstances which handicap the technical management of coal mines.

I have the greatest respect for any one who has to do with practical coal mining, a difficult, dangerous and heart-breaking job, but the fact remains there are enormous savings to be made in the colliery industry, of which of course the Report gives no indication. As already stated in a letter in your issue of July 18, the colliery boiler plants use about $6\frac{3}{4}$ per cent. of the coal raised, that is for average years, say, 17,500,000 tons out of 260,000,000 tons. The nett working efficiency of colliery boiler plants is 55·5 per cent., and individual plants are running at anything from say $32\frac{1}{2}$ to $72\frac{1}{2}$ per cent. efficiency, the lower figure being due to the egg-ended boiler, a few of which are still in use. Incidentally it may be stated this type of boiler was invented about 1750, and the average efficiency is much less than 40 per cent.

If scientific methods were adopted, the efficiency of colliery boiler plants could be raised to 70 per cent., and 3,625,000 tons of coal saved. Based on the examination of about 400 colliery boiler plants I should say, roughly, that the average installation consists of "Lancashire" boilers entirely in the open air, with a very moderately efficient covering over the top and none at all on the boiler fronts, no feed-water economisers, no superheaters, very badly leaking brickwork and poor working conditions for the firemen, very inefficient pipe coverings, leaky joints, and bad feed-water, although there is generally ample boiler capacity.

It is not to be wondered at therefore that the average efficiency is 55·5 per cent., and it gives some idea of the utter neglect of scientific principles of steam generation when we reflect that the average boiler-plant efficiency of all the industries of the country is only about 58 per cent., and collieries are therefore not very much worse than the average. But another serious loss of efficiency in colliery operation is the neglect to use refuse fuels, of which millions of tons have been thrown away in the shape of anthracite "duff," pit sweepings, washery "slurry," high-ash content material and coke breeze (from coke-oven equipment.) At least another 2,500,000 tons of coal could be released for sale if part of such refuse fuels were used under the steam boilers. Why have not the colliery industry opened research stations and solved these and other problems?

As already indicated, I do not want to give the impression that the colliery industry is much inferior in this respect to any other, but we are squandering our coal and other resources in every direction simply because technical men such as the chemist are either not employed at all, or else regarded as of little or no importance and paid accordingly.

I have no space to deal with many other items in the Report, but the advantages of the super-power station are grossly exaggerated, no mention is made at all of the "pass-out" or "bleeder" principle, and low-temperature carbonisation is almost ignored, although one very promising principle —that of carbonising coal in front of steam boilers, as in the Merz and MacLellan process in England and that of Pintsch in Germany—is mentioned, presumably because the Report is largely a popular and very slipshod appeal for the super-power station.—I am, Sir, etc.,

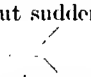
David Brownlie

A SUGGESTION

Sir,—Some little time ago you were kind enough to admit to the *Journal* a letter from me in which it was suggested that to allow of higher rates of movement of canal boats an "incurved collar" should be adjusted to the sides of canals to throw back the wash.

As cheap carriage, and quicker carriage, of heavy chemicals, and other materials, is of prime importance I am asking indulgence to make another suggestion, based on some laboratory experiments. The suggestion is to abandon the stern screw propeller for canals and use air expelled under moderate pressure from a considerable number of small openings arranged on the sides of the boat, or vessel, so that the air escapes in a direction *almost* in line with the side and slightly directed downwards.

Compressing the necessary volume of air is neither difficult nor expensive. The form of jet or opening that seems to meet most resistance from the water is one where the airpipe opens out suddenly into a cone or funnel of about 60°



Water full of air bubbles does not appear to have the same erosive power as the "solid" water driven by the propeller.

The water between the sides of the boat and the sides of the water container is filled with air bubbles which soften the swell and rush.

The arrangement of jets in slanting lines from about one foot under water to nearly the bottom of the boat sides would probably be the most efficient and the orifices of the air tubes half inch by one-eighth inch elipses ⬭ seem better than circles.

The best number of rows or series of these escape holes and their arranging and the pressure are matters requiring more elaborate experiments such as might be done at the N.P.L.

It will be agreed that by some means we must quicken canal traffic and when some start is made in this line possibly our derelict canals may be brought back to life.—I am, Sir, etc.,

W. R. Hodgkinson

Deep Cut, Hants
July 1924

PERSONAL AND OTHER ITEMS

The Canadian Institute of Chemistry has elected the following executive for the ensuing year. President, Dr. A. T. Charron; Vice-Presidents, Prof. R. Harcourt, J. W. Shipley, C. E. Wallen; Secretary, L. E. Westman; Treasurer, E. T. Sterne, and the following representatives were elected to the council to replace those retiring, Prof. E. H. Archibald, Vancouver; L. F. Cooper, Calgary; E. T. Sterne, Brantford; Prof. G. S. Whitby, Montreal, and F. Barnes, Shawinigan Falls.

At Oxford, Mr. A. J. Walker, B.A., Queen's College, has been elected to a scholarship for research in physical science of £200 a year for two years, to enable him to pursue research in organic chemistry.

The board of governors of the University of Toronto has awarded to S. C. Blaylock, general manager of the Consolidated Mining and Smelting Company of Canada, Trail, B.C., the McCharles prize for his work in connexion with the production of electrolytic zinc, and with the solving of the difficulty of treating complex lead, zinc and silver ore. Mr. Blaylock accepted the prize as Captain of the team, and it is to be distributed among the members of the staff. The money part of the prize has been given to the Trail Memorial building.

On August 15 the marriage was solemnised of Miss Eva S. E. Coleman, B.Sc., daughter of Mr. W. H. Coleman, and Dr. W. M. Cumming, senior lecturer in organic chemistry in the Royal Technical College, Glasgow.

The *Times* states that Glasgow Corporation, which opened a chemical department five years ago in association with the municipal gas works, made a profit last year of £270,000 from by-products.

On the occasion of the meeting of the British Association in Toronto, a special Convocation of the University of Toronto has conferred honorary degrees of Doctor of Science on Sir David Bruce, Sir Ernest Rutherford, Sir Charles Parsons, and Sir Edward Russell.

The following deaths are announced from Germany: Dr. K. Waldeck, technical director of the Nitrogen Stickstoffdünger- und Chemische Industrie A.-G., and R. Balhorn, founder of the Ruba soap works.

The death is announced of Sir Samuel Turner, founder of the firm of asbestos manufacturers bearing the same name.

J. H. Cremer, who died in July at Spartanburg, S.C., at the age of 80, had long been connected with the steel industry, and is said to have been the first to produce ferromanganese on a commercial scale in the United States.

We regret to announce the death of Mr. W. R. Bird, who was recently elected Chairman of the South Wales Section of the Society of Chemical Industry. Mr. Bird was returning from a motoring tour on the Continent when he was taken ill at Staines, and died after an operation. He was a director of Bird and Son, Ltd., Cardiff, tar distillers and oil importers, and was a willing worker in social and educational movements.

The centenary of the death of Karl Arnold Kortum, one of the last alchemists, fell on August 16.

Prof. Albert Hesse, for many years editor of the *Chemisches Zentralblatt*, has died in his fifty-eighth year. After studying natural philosophy at Münster, Berlin, and Göttingen, he gained his doctorate with a work on the terpenes. After a short time as chemical assistant at Göttingen he went into chemical industry, and contributed to the literature of chemical technology, being especially interested in ethereal oils. In 1902 he became editor of the *Chemisches Zentralblatt*. He was also known for his interest in economic and social questions in their relation to chemical industry.

With regret we announce the death, at the age of 64, of Prof. J. Wertheimer, dean of the Faculty of Engineering and Professor of Applied Chemistry in the University of Bristol. Educated at University College, Liverpool, and Owens College, Manchester, he was headmaster of the Leeds School of Science and Technology from 1887 to 1890, when he became principal of the Merchant Venturers Research College at Bristol. When Bristol University was founded and its faculty of Engineering absorbed the Technical College, Prof. Wertheimer became dean of the Faculty. He had published text books on chemistry, and had edited a series of technological works. In addition to valuable services to the University he served on various public bodies and, during the war, he organised the West of England industrial reserve for the production of munitions.

We regret to announce the death of Mr. Edward M. Johnson of the firm of Messrs. Locke, Lancaster and Johnsons, London, well-known as manufacturers of white-lead and other lead products. Mr. Johnson died on August 13 and was buried in Little Missenden Churchyard on August 16. The funeral was attended by many of his business friends, all of whom liked and respected him. He was 59 years of age.

GENERAL

Metallurgy in Belgium in 1923

The output of coal amounted to 22,916,070 tons (against 21,208,500 t. in 1922); coke, 4,156,700 t. (2,849,884 t., in 1922). The number of blast furnaces alight at the end of the year was 40, being 6 more than at the beginning of 1923, and 14 less than the total number alight on December 31, 1913; at the beginning of 1922 there were only 14 blast furnaces. The production of cast iron was 2,188,130 tons (1,605,620 t. in 1922); steel, 2,216,650 t. (1,497,610 t. in 1922); finished steel, 1,943,390 t. (1,409,990 t. in 1922), finished iron, 207,740 t. (180,252 t. in 1922). The production of zinc rose to 148,080 t. against 113,137 t. in 1922. The output of crude zinc by the Vieille Montagne Co. was 73,000 t. in 1923, compared with 63,000 t. in 1922. Amongst the products were 57,500 t. of sheet and worked zinc, and 24,600 t. of various zinc oxide and other oxide. Production by the same company included 11,400 t. of pig and 4400 t. of sheet lead, whilst the smelters produced 68,627 t. of sulphuric acid.

REVIEWS

The Simple Carbohydrates and the Glucosides. By E. Frankland Armstrong, D.Sc., Ph.D., F.R.S. (Monographs on Biochemistry, edited by R. H. A. Plimmer and F. G. Hopkins). Fourth Edition. Pp. xi+293. London: Longmans, Green and Co., 1924. Price 16s. net.

It is just fourteen years ago since the first edition of this monograph was published and the demand for three succeeding and enlarged editions shows not only the rapid development of the subject, but it is also a tribute to the manner in which the author has performed his task. The present edition has been thoroughly revised, and some 50 pages and two chapters added to the text. The author mentions Principal Irvine, Dr. T. P. Hilditch and Mr. Rex Furness as having given him many valuable suggestions. It must be distinctly understood that the monographs of this series do not aim at being full treatises on the subjects they deal with, the text being subsidiary to the bibliographical tables. This fact has been kept well in mind in any criticisms which the writer has been tempted to make of the present work.

There are few chapters in organic chemistry which present such fascination to the student as that dealing with the sugars, uniting as it does the work of the pure chemist and of the biochemist better than perhaps any other in the whole range of chemical literature. Nor can we forget that the story presented so ably in the present monograph is due to the researches of a single chemist, Emil Fischer. "The outstanding feature of his method," says Dr. Armstrong, "was his absolute devotion to experimental enquiry, the unwearying persistence of his efforts to attain a clearly foreseen goal, the gradual but always logical manner in which problems were approached, and the completeness of his attack. No one previously had set the same example of ordered, persistent enquiry." It certainly befits the case that the task of writing a monograph on the sugars should fall to the lot of one of Fischer's former pupils and assistants.

Fischer died in 1919, and he bequeathed to the world in general and to science in particular the rich legacy which is summarised in the present work. We owe to him the general scheme of the chemistry of the simple sugars as well as the conception of the glucosidic nature of the more complex members of the carbohydrate group. True lacunæ have been filled in here and there by other workers, but the frame work of the edifice is Fischer's and Fischer's only. Thus it would seem that with Fischer's death the subject of sugar chemistry passed from the hands of an individual into those of a community. Individual effort, however, still counts, and in this connexion it will not be invidious to mention the work emanating from the St. Andrews School, commenced by Purdie and continued by Irvine at St. Andrews and by Haworth at Newcastle, as well as that of C. S. Hudson in America. From both sources valuable results have already accrued, and we may anticipate a still richer harvest in the future.

Of the eleven chapters in this monograph the first four deal with the simple sugars (including the cycloses) and their derivatives; the fifth and seventh are devoted to the disaccharides and polysaccharides respectively; the sixth is concerned with hydrolysis and synthesis; whilst the subject matter of the remainder is under the following headings: The relation between configuration and biological behaviour, the natural and synthetic glucosides (two chapters), and the function of carbohydrates and glucosides in plants.

As regards the aldoses the bulk of the space is devoted to d-glucose and its derivatives, as being the best known typical member of the group. The ketoses are also dealt with though not at such great length. The author now favours the use of numerals instead of Greek letters to indicate the carbon atoms to which the oxygen ring is attached, thus avoiding confusion. Much importance is quite rightly attached to the evidence which has been brought forward of the existence of a new form of hexose, the γ-form, and in this connexion the writer is pleased to note that Irvine's recent suggestion is mentioned, namely, that the so-called γ-sugars may not be chemical individuals but simply the sugars acting as aldehydes and ketones. This suggestion receives support from the work of Ling and Nanji on the action of ammonia on glucose, as well as from some more recent work carried out in the writer's laboratory on the reduction of the sugars in which the presence of ammonia has been found necessary.

The existence of isomaltose is now regarded by the author as definitely established through the work of Ling and Nanji, but although mention is made of the isomaltose of Fischer which the author also isolated independently, no hint is given that the two sugars may be, and probably are, distinct substances. The hexatriose α-glucosidoisomaltose of Ling and Nanji should have been referred to under the trioses: it is even better characterised than isomaltose as it possesses a sharp melting point.

In dealing with a biochemical subject, the organic chemist is too apt to insist on the necessity of reactions proceeding by stages, forgetting that in the nature the dictum of the Greek philosopher, πάντα ῥεῖ applies. On p. 174 the early suggestion of E. Buchner and his co-workers that lactic acid or alternatively dihydroxyacetone are intermediate products in the alcoholic fermentation of the sugars is mentioned. The former was shown by Slator to be unfermentable by yeast, whilst the latter is only slowly fermentable. It may be pointed out, however, that many intermediaries have no actual existence at any given interval of time, *e.g.*, formaldehyde in the photosynthesis of the carbohydrates. They serve merely to indicate the paths through which the changes travel, and they can only be isolated when substances combining with them and removing them from the sphere of action are present. The author, however, evidently agrees with this view, for he states that dihydroxyacetone is probably fermented by yeast only after it has been converted into hexose, which is supported by Lebedeff's observation that the organic phosphate produced during the fermentation of dihydroxyacetone is identical with the hexose phosphate of Harden and Young.

The author states that the knowledge of the more complex carbohydrates having reached a stage when structural formulæ can be assigned to them with some degree of certainty, it has been felt desirable to introduce a new chapter dealing with so much of the chemistry of these substances as is required for the purpose. This statement disarms criticism. The new chapter covers 10 pages and is devoted entirely to structural considerations deduced from purely chemical work without reference to the action of enzymes. Most of the structural formulæ which have been proposed for the basal unit of cellulose are reproduced, including that of Irvine, tri-1 : 5 anhydroglucose. This latter requires that cellulose shall yield 70 per cent. of cellose, whereas the highest recorded yield which the writer has been able to find is 60 per cent. of cellose octacetate by Klein in 1912, which has been confirmed, although Karrer and Widmer state that cellulose contains more than 50 per cent. of cellose complex. There can be no doubt that cellulose yields on complete hydrolysis nothing but glucose as this has been established by Irvine. It would seem not improbable, however, that cellulose like starch consists of more than one polysaccharide. Hess, whose highly important work is not mentioned, brings forward evidence that cellose is a reversion product and also points out that cellulose itself is not a single substance.

With regard to starch, it is pointed out that the structural formula for the basal unit of amylopectin proposed by Ling and Nanji is a dimeric form of Irvine's triose formula for starch. No mention is made of the presence of hemicellulose in certain starch granules, notably in rice starch with which Irvine worked, as first pointed out by Sehryver.

Glycogen is dismissed in eight lines; it is said to take the place of starch in animals, but its sources in the vegetable kingdom are not alluded to. The other polysaccharides briefly noticed are inulin, mannan and xylan.

But few additions have been made to the highly suggestive concluding chapter on the function of carbohydrates and glucosides in plants. Physiologists have objected to the application of their word "hormone" by H. E. and E. F. Armstrong to denote substances such as hydrogen cyanide, hydrocarbons, alcohols, phenols, esters, ethers, etc., including as the author remarks, most of the substances which Overton and others have classed as solvents for lipoids—which are able to penetrate the walls of plant cells. Bayliss contends, for example, that the action of these substances should be looked upon as due to the removal of some obstacle which prevents access of an enzyme to a glucoside. That was certainly the way in which Overton [illegible] the phenomenon.

The [illegible] paragraphs in the chapter deal with the tannins and with the genesis of the carbohydrates in certain of the gramineæ.

In the bibliography the writer notices the omission of one or two papers cited in the text. The early editions of Czapek's "Biochemie der Pflanzen" and of Tollens's Kurzes Handbuch der Kohlenhydrate" are quoted instead of the latest editions.

In conclusion the writer would like to be permitted to add his tribute to the merit of Dr. Armstrong's monograph. It is a summary of the subject which will prove invaluable as a guide to the literature, not only for research workers, but also for those teachers whose lectures are based on original memoirs rather than on text books. Not the least important feature of the work is, moreover, the many suggestions which it contains, the value of which can only be appraised by the authority with which the author is able to speak on a subject which he has made his own.

Arthur R. Ling

Kurzes Lehrbuch der Chemie. By Werner Mecklenburg. Second Edition. Pp. xvi+793. Brunswick: F. Vieweg and Son, 1924. Price, paper 20 m., bound 23 m.

This book is based upon, and forms the thirteenth German edition of, Roscoe's "Lessons in Elementary Chemistry," which first appeared in 1866 and was translated, among other languages, into Chinese. Of the body little remains, but the spirit of Roscoe's book is preserved. The treatment is clear, with a practical tendency, and is descriptive rather than speculative. The theoretical portions are clear and adequate. The sections on the Phase Rule, in this connexion, are particularly good: cooling curves, the theory of double salts, reciprocal salt pairs, and alloys are dealt with very well. The description of the metals includes very brief accounts of the so-called "rare elements," and in this part the only thing which seems open to criticism is the treatment of the Periodic Law at the very end of the whole section.

The Organic section is very readable yet fairly detailed. Important technical details and the chemistry of daily life receive attention. This section is well balanced and up to date. The preparation of phthalic anhydride by air oxidation, the "impossible" compound triphenylmethyltetramethylammonium—$(C_6H_5)_3C{\cdot}N(CH_3)_4$—in which all five valencies of nitrogen are directly united with carbon, the compound $(C_6H_5)_2:N;O$, and the use of "tetralin" in artificial motor spirit (25 per cent. tetralin+25 per cent. alcohol+50 per cent. benzene), are all included. The book is well printed on good paper and the diagrams are clear.

J. R. Partington

Modern Electro-Plating: A Guide Book for Platers, Works Chemists and Engineers. By W. E. Hughes, M.A. Pp. vii+160. London: H. Frowde and Hodder and Stoughton, 1923. Price 16s.

This book, as its author states in his foreword, is essentially a collection of articles published from time to time in the official journal of the British Electrical and Allied Manufacturers' Association. Interested readers who followed these articles will be glad to have them in more permanent form. It was very unfortunate, however, that the author in arranging these in book form did not see his way to enlarge on the technological side of the subject.

The book is addressed particularly to platers, works chemists and engineers. Of these three classes, it will unquestionably be of most value to the second

named. It is difficult to imagine that the average electro-plater or even the average engineer would find very much assistance from the critical discussions of the work of other writers and investigators on the subject of the electro-deposition of metals with which this book is so freely interspersed. At the same time, to the works chemist, and particularly to the works chemist engaged in what may be termed "industrial research," the book contains very much of permanent value, and the critical descriptions of published literature on the subject will be very useful.

The chapter on the structure of electro-deposited metal fairly adequately fills a definite blank in existing text books on the subject, and is a subject with which the author is very well qualified to deal, since he has himself carried out some valuable investigations.

One serious defect of the book is the omission of any consideration of the precious metals, especially silver and gold. The electro-deposition of these two metals forms a very important section of the industrial electro-deposition of metals, and one is compelled to protest very vigorously against the undeservedly slighting references which are made in the one short paragraph in which silver receives mention at all. It is quite true that the basis of commercial silver plating is the "poisonous" cyanide of potassium, but the author does not hesitate to recommend essentially the same type of solution for copper. And one fails to see any really sound objection to the use of cyanide solutions under modern workshop conditions.

A further omission of importance is that of the deposition of alloys, particularly brass, a subject upon which the works' chemist or works' manager is very often in need of technical information.

In spite of these very obvious defects, however, the book is a welcome addition to the meagre literature of electro-plating.

W. R. Barclay

Kelly's Directory of Merchants, Manufacturers and Shippers of the World. 1924. Thirty-eighth edition. Vol. I, pp. ccci+2522. Vol. II, pp. cxviii+2158. London: Kelly's Directories, Ltd., 186, Strand, W.C. 2. Price 64s.

The new edition of Kelly's Directory includes all the well-known and useful features of previous editions. In volume I (the world, other than the British Empire), further information has been added to the section devoted to Russia, which, like the sections relating to other countries is provided with a sketch map showing the chief means of communication and some condensed information useful to traders. The second volume relates solely to the British Empire, in which the useful innovation has been made of including an alphabetical list of telegraphic addresses in Great Britain and Ireland. The information given appears to be remarkably comprehensive and the clear arrangement facilitates quick reference. The utility of Kelly's Directory is only fully realised when the copy is wanted while being used by someone else, and it is of value to many who are not traders.

REPORTS

Report on the Economic and Financial Conditions in Germany, April, 1924, by J. W. F. Thelwall, Commercial Secretary, Berlin, and On the Occupied Territories, by C. J. Kavanagh, Commercial Secretary, Cologne. Department of Overseas Trade. Pp. 190. H.M. Stationery Office, 1924. Price 5s.

The outlook in Germany was no more definite at the beginning of this year than it has been at any time since the war (*cf. Chemistry and Industry*, 1923, 683). During practically the whole of 1923 the country was cut off economically from the Occupied Territories and had to resort to far-reaching adaptations to meet the situation. Currency difficulties were great; the failure to establish the new gold mark led to the introduction of the rentenmark, a form of currency available only for home use and not quoted on the exchange, but which seems likely to fulfil its purpose of restoring normal conditions and paving the way to the introduction of a gold currency.

During the year German trading policy underwent a revision, and the restrictions on exports were drastically cut; a policy of protection hinders importation, but in this trade also some relaxation of the regulations has been made. The occupation of a large proportion of industrial Germany has made her dependent on imports even of some kinds of iron and steel goods. The textile industries did better in 1923 than in the previous year, exports showing an increase and imports a decrease. The export figures in the chemical and dyestuffs trades are comparatively good; the demand for potash salts and fertilisers showed an increase, but that for chemical and pharmaceutical preparations fell. Rubber goods, porcelain, earthenware and glass showed considerably increased exports. The total imports in 1923 were less than in 1922, but those of foodstuffs increased, as did also those of coal and coke, on account of reparations, deliveries and the Ruhr occupation.

In the report on the Occupied Territories is given an account of the chaotic conditions which prevailed during the Ruhr resistance and the currency debâcle. At present the territories are experiencing a phase intermediate between inflation and devaluation. The relations between the industrialists and the bankers are somewhat similar to those which arose in this country after the post-war boom; German manufacturers are not, however, saddled with large stocks, and once their financial problems are settled should find it easier to return to normal conditions. The value of the occupied areas lies chiefly in the coal-mining, metallurgical and chemical industries. Of the whole German coal resources, about 120 million t. per annum, 90 per cent., is now in occupied territory. This coal is the basis of German prosperity; about one-half is used in metallurgical industries, Lorraine also drawing on this source for coke. About 80 per cent. of the iron and steel works are situated in this area, which has a production equal to that of Great Britain. The Rhineland also draws on this district for supplies of coal-tar products.

Report on the Economic and Commercial Conditions in Turkey, April, 1924. By Col. H. Woods, O.B.E., Commercial Secretary, Constantinople. Department of Overseas Trade. Pp. 52. H.M. Stationery Office, 1924. Price 1s. 6d.

In the Turkish agricultural industry output was below normal in 1923, but prospects for 1924 are good. The Government has recently voted large sums to subsidise the industry, distributing seed and machinery gratuitously. Manufacturing industries have always been of minor importance, and military operations have resulted in the partial destruction of even the small industrial centres which existed before the war. The wine and spirit industry has been ruined by the introduction of a "dry" régime, and vine-growers have also suffered accordingly. The silk industry improved last year, but, as in all the manufacturing industries, lack of skilled labour, owing to the migration of Christians, has proved a great difficulty.

Trade in 1923 suffered from the political conditions as well as customs difficulties, and stocks of imports were kept as low as possible. The total imports were 458,744 t., and exports 350,484 t., most of this trade passing through Constantinople and Smyrna. The greatest value of imports was obtained from Great Britain, Italy coming second; the staple export from both countries to Turkey is cotton, and Italian competition in this line with British merchants has become severe. Detailed advice is given to assist British traders in selling their goods in Turkey.

Report on the Financial, Commercial and Economic Conditions in Rumania, March, 1924. By A. Adams, Commercial Secretary, Bucarest. Department of Overseas Trade. Pp. 66. H.M. Stationery Office, 1924. Price 2s.

The principal feature in the trade of Rumania during 1923 was the continued vitality of the importation of staple articles from Britain (*cf. Chem. and Ind.*, 1923, 776). Cotton textiles, sheet iron, iron bars, agricultural machinery and coal remained the chief articles in demand. The general conditions in the import trade have been such as to discourage big orders, and traders have generally taken the easiest terms of payment offered, which do not often come from British manufacturers. Chemicals are now difficult to obtain from Germany, and there should be a good demand for British chemical and pharmaceutical products if properly advertised. Coal imports dropped almost to zero during the war, but are now improving, though recent figures are not available.

The agricultural industry is making progress. Restrictions on cereal exports have been removed, giving an immense fillip to the trade, and the area under cultivation is increasing. The 1923 harvest was the best for some years.

The production of crude petroleum in 1923 was 1,509,804 t., showing an increase over previous years since the war. Export of crude oil is prohibited, and general restrictions are in operation in order that the country may obtain as much benefit as possible from the industry. Borings were made during the year to the extent of 114,705 metres. All mining properties in Rumania are to be held by the State. The coal production during 1923 is not yet known, but is expected to be larger than in 1922, when 2,116,000 t. was won. The production of salt in 1923 was 285,212 t. The sugar crop was good, and an export of 10,000 t. is anticipated. During the year 190,000 t. of Portland cement was produced, more than sufficient for local needs, which are, however, expected to increase. The metallurgical industries were hampered by the shortage of coke, as well as by financial difficulties. The problem of uniting the industries of Transylvania with those of the Old Kingdom are gradually being overcome, not only in the metallurgical industries but also in others of a more general nature.

Report on the Economic, Financial and Industrial Conditions in Finland, March, 1924. By C. H. Mackie, H.M. Consul, Helsingfors. Department of Overseas Trade. Pp. 68. H.M. Stationery Office, 1924. Price 2s.

In some respects the year under review was les satisfactory than 1922 (*cf., Chem. and Ind.*, 1923 1015). The large exports of that year were chiefl due to the depreciated currency of the country, bu since stabilisation was begun at the end of 192 the decrease in exports has been very marked. Export in 1923 were valued at 4385 million F. marks against 4468 million F. marks during the previou year. Great Britain takes more than one-third of t. exports from Finland. Imports in 1923 were valu at 4607 million F. marks, against 3970 million marks in 1922. Germany supplies about 30 per cen of the imports, Great Britain about 18 per cent., an the United States about 12 per cent. Great Britai is the chief supplier of coal, coke and textiles. Th demand for coal rose steadily during 1923, 524,670 t being imported, more than twice the total in 1922 a somewhat smaller demand is expected during th current year. Most of the chemicals imported ar obtained from Germany, which also supplies th bulk of the colours and colouring matters.

Industry experienced an uneventful year, findin great difficulty in obtaining sufficient working capita The boom in the textile industry in 1922 gave wa to a depression last year, when accumulated stock had to be worked off. The high cost of productio has led to a decrease in the export trade in glass, an factories are no longer working to capacity. Som paper mills are doing well, but others have had t suspend operations.

Dr. L. Benda, to whom was due the preparation of salvarsan, trypaflavin and similar compounds, recently celebrated his 25th year of service with Cassella und Co., Frankfort.

COMPANY NEWS

THE MAGADI SODA CO., LTD.

The proposals of Brunner Mond and Co., Ltd., for the reconstruction of the Magadi Soda Co., Ltd., have now been issued, and the chief points of the scheme are: A new company is to be formed with a share capital of £830,000, divided into 250,000 6 per cent. first preference of £1 each; 1,320,000 6 per cent. second preference of 5s. each; 600,000 12½ per cent. preferred ordinary of 5s. each; and 100,000 ordinary of £1 each. The new company is to issue £500,000 6 per cent. first mortgage debentures redeemable in 1945 at par, by means of a sinking fund commencing in 1929. For the first two years the debenture interest and dividend on preference shares are to be paid out of any profits for each year, but afterwards the interest and dividends become cumulative. Dividend on the preferred ordinary is only to be paid if earned and will be non-cumulative. Preference and preferred ordinary shares will have no voting right for the first two years, but voting power is given after that time on certain conditions. One director is to be nominated by the Governor of Kenya Colony, one by the present trustees for the first debenture holders, and the remainder by Brunner Mond and Co., Ltd. The names of the first directors have to be approved by the Colonial Office and by the Senior Official Receiver. The proposals for exchanging debentures and shares are: Each first debenture to be exchanged for a debenture in the new company for the same amount, all interest arrears being cancelled. Holders of second debentures and each unsecured creditor to receive the first preference shares equal in nominal value to 75 per cent. of the former company's indebtedness, all interest on second debentures and unsecured debts being cancelled. Each ordinary share to be exchanged for one second preference credited as fully paid; every twenty deferred shares to be exchanged for one second preference fully paid. Each holder of ordinary and deferred shares of the former company to have the right to subscribe in cash at par for the 600,000 preferred ordinary in proportion to holding of second preference. Provision is to be made for payment in full of certain creditors, such as the Government of Kenya Colony, Uganda Railway, etc.

The total amount of these debts is not to be more than £20,000, and will be provided by the new company. Brunner Mond and Co., Ltd., are to be allotted at par 100,000 ordinary shares to be paid for in cash, and such preferred ordinary shares as are not taken up by the second preference shareholders. Brunner Mond and Co., Ltd., will give guarantees to the satisfaction of the Official Receiver and the Colonial Government that the company will work the Magadi Soda Co.'s property to its full economic capacity. The scheme is subject to a lease being granted by the Colonial Office to the new company.

Mr. F. W. Babington, chemist in charge of the laboratory of Customs and Excise, Ottawa, is retiring on pension.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech.	£23 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	£45 per ton.
Powder	£47 per ton.
Acid Hydrochloric	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers' works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder	Spot £11 d/d.; Contract £10 d/d 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Methylated Spirit 64 o.p.—	
Industrial	3s. 1d.—3s. 5d. per gallon, according to quantity.
Mineralised	4s. 2d.—4s. 6d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	5¾d. per lb.
Potass. Chlorate	3d.—4d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£3 10s. per ton d/d.
Soda Caustic, solid	Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals	£5 5s—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton, carr. paid.
Sod. Bichromate	4½d. per lb.
Sod. Bisulphite Powder 60/62%	£18—£19 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Sulphide conc. 60/65	About £14 10s. per ton d/d.
Sod. Sulphide cryst.	£9 per ton d/d.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	5¾d.—1s. 4d. per lb., according to quality.
Crimson	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 11d. per lb.
Barytes	£3 10s. to £6 15s. per ton, according to quality.

Cadmium Sulphide	3s. 9d.—4s. per lb., according to quantity.
Carbon Bisulphide	£29—£31 per ton according to quantity.
Carbon Black	7d.—7½d. per lb. ex wharf. Dearer.
Carbon Tetrachloride	£56—£60 per ton according to quantity, drums extra.
Chromium Oxide, green	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	5d.—7d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	44s. 9d. per cwt., barrels free.
Lead Hyposulphite	7½d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£16 5s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Sulphur Chloride	3d. per lb., carboys extra.
Thiocarbanilide	2s. 6d. per lb.
Vermilion, pale or deep	5s. 1d. per lb. dearer.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£14 10s. per ton d/d. Demand active.
Grey	£19—£20 per ton. Fair demand.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 per ton, according to grade and locality. Demand below normal.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. ,, 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 7d. per gall. Unrefined.
Wood Naphtha—	
Miscible	5s. per ga[illegible]% O.P. Market dull.
Solvent	5s. 6d. per gall. 40% O.P. Fairly good demand.
Wood Tar	£5 per ton.
Brown Sugar of Lead	£46 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	6½d. per lb. Quiet.
Crude 60's	1s. 9d.—1s. 11d. per gall., according to district. Still quiet.
Acid Cresylic, 97/99	2s 1d.—2s. 2d. per gall. Demand still good. Market firm.
Pale 95%	1s. 10d.—1s. 11d. per gall. Quiet.
Dark	1s. 9d. per gall. Quiet.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	8d.—9d. per gall. Quiet.
Unstrained	7d.—9d. per gall.
Benzole—	
Crude 65's	10½d.—1s. per gall. ex works in tank wagons.
Standard Motor	1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure	1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.
Toluole—90%	1s. 5½d. per gall.
Pure	1s. 8d.—2s. per gall.
Xylol coml.	2s. 3d. per gall.
Pure	3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	8½d. per gall. Not much business.
Middle Oil Heavy Oil Standard Specification	5½d.—6d. per gall in Lancashire 6d.—7d. per gall. in Yorkshire.

Naphtha—	
Solvent 90/160	1s.—1s. 3d. per gall. according to district. Market flat.
Solvent 90/190	1s.—1s. 1½d. per gall. Demand maintained.
Naphthalene Crude—	
Drained Creosote Salts	£4—£6. Quiet.
Whizzed or hot pressed	£9 per ton. Little business.
Naphthalene—	
Crystals and Flaked	£13—£16 per ton in Yorkshire and London respectively.
Pitch, medium soft	55s.—60s. per ton f.a.s. for next season. Frequent inquiries.
Pyridine—90/160	18s.—18s. 6d. per gall. demand.
Heavy	12s.—12s. 6d. Little busine

INTERMEDIATES AND DYES

In the following list of Intermediates delivered include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 7d. per lb.
Acid H.	4s. per lb 100% basis d
Acid Naphthionic	2s. 4d. per lb. 100% ba
Acid Neville and Winther	5s. 8d. per lb. 100% basis d
Acid Salicylic, tech.	1s. 1d. per lb. Improved
Acid Sulphanilic	9½d. per lb. 100% basis
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	7¾d.—8¼d. per lb. naked at works.
Aniline Salts	7¾d.—9d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 1d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 19/31° C.	4½d. per lb. Demand steady.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Deman moderate.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Deman moderate.
Dichloraniline	2s. 3d.—2s. 11d. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£85 per ton.
Diethylaniline	4s. 6d. per lb. d/d., pac ed extra, returnable.
Dimethylaniline	2s. 3d. per lb. d/d. Drums
Dinitrobenzene	9d. per lb. naked at works.
Dinitrochlorbenzol	£84 10s. per ton d/d.
Dinitrotoluene—48/50° C.	8d.—9d. per lb. naked at w
66/68° C.	1s. 2d. per lb. naked at wo
Diphenylamine	2s. 10d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 4d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	4s. 9d. per lb. d/d.
p-Nitraniline	2s. 3½d. per lb. d/d.
Nitrobenzene	5¼d.—5½d. per lb. naked at work
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	10½d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-o-amido-phenol	4s. 6d. per lb. 100% basis
m-Phenylene Diamine	4s. per lb. d/d.
p-Phenylene Diamine	10s. 3d. per lb. 100% basis d/d.
R. Salt	2s. 6d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 3d. per lb. 100% basis d/d.
o-Toluidine	8½d. per lb.
p-Toluidine	3s. 3d. per lb. naked at works.
m-Toluylene Diamine	4s. 3d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	£45 per ton.
Acid, Acetyl Salicylic	3s. 2d.—3s. 4d. per lb., according to quantity. Good demand. Price firm.

Acid Boric B.P.	Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	19s.—21s. per lb.
Acid, Citric	1s. 5½d.—1s. 6d. per lb., less 5% for ton lots. Market very weak.
Acid, Gallic	3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst.	6s. 9d. lb. Resublimed quality 8s. per lb. Market firm; increasing demand.
Acid, Salicylic	1s. 6d.—1s. 9d. per lb. Market unsettled and difficult.
Acid, Tannic B.P.	3s. per lb. Market quiet.
Acid, Tartaric	1s. 1¼d. per lb. less 5%.
...dol	9s. per lb. d/d.
...anilide	2s. 1d.—2s. 3d. per lb. for quantity. Demand slow.
...pyrin	13s. 3d. per lb. Neglected. Stocks low.
...n. Benzoate	3s. 3d.—3s. 6d. per lb. according to quantity.
...a. Carbonate B.P.	£37 per ton.
...b Sulphate	12s. 6d. per oz. for English make.
...o.	15s.—15s. 6d. per lb. Quiet market.
...phthol	5s. 3d. per lb. Small inquiry.
...Salts	Prices according to quantity.
Carbonate	12s. 9d.—14s. 9d. per lb.
" Citrate	11s. 4d.—13s. 4d. "
" Salicylate	10s. 2d.—12s. 2d. "
" Subnitrate	10s. 9d.—12s. 9d. "
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
...romides	Unsettled. Spot supplies short. Raw materials dearer. Market very firm and advancing.
Ammonium	1s. 3d.—1s. 6d. per lb.
Potassium	1s. 1d.—1s. 4d. per lb.
Sodium	1s. 2d.—1s. 5d. per lb.
...lcium Lactate	Demand active. Good English make can be had from 1s. 7d. to 2s. 6d. per lb.
...oral Hydrate	4s.—4s. 3d. per lb. Very firm and scarce.
...loroform	2s. per lb. for cwt. lots. Very steady.
...ote Carbonate	6s. 6d. per lb. Little demand.
...ldehyde	£52 per ton, ex works. English make in casks.
...rophosphates—	Fair business passing.
...cium, soluble and ...itrate free	7s. per lb.
...on	8s. 9d. per lb.
Magnesium	9s. per lb.
Potassium, 50%	3s. 6d. per lb.
Sodium, 50%	2s. 6d. "
...uaiacol Carbonate	10s. 6d.—11s. 3d. per lb.
Hexamine	3s. 6d. per lb. for English make. Market steady.
Homatropine Hydrobromide	30s. per oz.
Hydrastine hydrochlor	English make offered, 120s. per oz.
Hypophosphites—	
Calcium	3s. 6d. per lb., for 28-lb. lots.
Potassium	4s. 1d. per lb.
Sodium	4s. "
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 5d. per lb., according to quantity.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£75 per ton, less 2½%.
Heavy Commercial	£25 per ton, less 2½%. Price reduced.
Heavy Pure	2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	62s. 6d. per lb. Market rising rapidly.
Synthetic	26s.—35s. per lb., according to quantity. English make. Strong demand.
Mercurials	Market flat.
Red oxide	5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	3s. 6d.—3s. 7d. "
White precip.	4s. 7d.—4s. 8d. "
Calomel	3s. 11d.—4s. "
Methyl Salicylate	1s. 10d.—2s. 1d. per lb. Keen competition.
Methyl Sulphonal	26s. per lb.
Metol	11s. per lb. British make.
Paraformaldehyde	2s. 10½d.—3s. per lb. Not very active.
Paraldehyde	1s. 5d.—1s. 6d. per lb. in free bottles and cases.
Phenacetin	6s. per lb. Price and demand steady.
Phenazone	7s. 6d. per lb. A shade firmer. Forward prices higher.
Phenolphthalein	6s. 6d. per lb. Ample supplies.
Potass. Bitartrate— 99/100% (Cream of Tartar)	88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate	1s. 10d.—2s. 2d. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues heavy.
Potass. Metabisulphite	7½d. per lb., 1-cwt. kegs included.
Potass. Permanganate	7½d. per lb.
Quinine Sulphate	2s. 3d. per oz. in 100 oz. tins. Very heavy demand.
Resorcin	5s. 2d. per lb.
Saccharin	63s. per lb., in 50-lb. lots.
Salol	3s. 6d. per lb.
Silver proteinate	9s. 6d. per lb.
Sod. Benzoate, B.P.	2s. 6d. per lb. Ample supplies. B.P. quality available.
Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity.
Sod. Hyposulphite— Photographic	£13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	75s.—82s. 6d. per cwt., according to quantity. Steady market, good demand.
Sod. Salicylate	Market more active. Powder 2s. 3d.—2s. 5d. per lb. Crystal at 2s. 5d.—2s. 7d. per lb. Flake 2s. 9d. per lb.
Sod. Sulphide— Pure recryst.	10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Sulphonal	15s. 6d. per lb. Easier.
Thymol	19s. 6d. per lb. nominal. Very scarce indeed. Still rising.

PERFUMERY CHEMICALS

Acetophenone	12s. 6d. per lb.	
Aubopine	15s. 3d. ,,	
Amyl Acetate	2s. 9d. per lb.	
Amyl Butyrate	6s. 9d. ,,	
Amyl Salicylate	3s. ,,	
Anethol (M.P. 21/22° C.)	4s. 6d. ,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 10½d. ,,	
Benzyl Alcohol free from Chlorine	2s. 10½d. ,,	
Benzaldehyde free from Chlorine	3s. 6d. ,,	
Benzyl Benzoate	3s. 6d. ,,	
Cinnamic Aldehyde Natural	16s. ,,	
Coumarin	19s. 6d. ,,	Cheaper.
Citronellol	17s. ,,	
Citral	9s. ,,	
Ethyl Cinnamate	13s. 6d. ,,	
Ethyl Phthalate	3s. 3d. ,,	
Eugenol	10s. 6d. ,,	Cheaper.
Geraniol (Palmarosa)	35s. ,,	
Geraniol	11s.—18s. 6d. per lb.	
Heliotropine	7s. 9d. ,,	
Iso Eugenol	15s. 9d. ,,	
Linalol ex Bois de Rose	26s. ,,	
Linalyl Acetate	26s. ,,	
Methyl Anthranilate	9s. 6d. ,,	
Methyl Benzoate	6s. ,,	
Musk Ambrette	45s. ,,	
Musk Xylol	14s. ,,	
Nerolin	4s. 9d. ,,	
Phenyl Ethyl Acetate	15s. ,,	
Phenyl Ethyl Alcohol	16s. ,,	
Rhodinol	57s. 6d. ,,	
Safrol	1s. 10d. ,,	
Terpineol	2s. 4d. ,,	
Vanillin	26s. per lb.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	15s. 6d. per lb.	
Aniso Oil	2s. 6d. per lb.	Cheaper.
Bergamot Oil	17s. 6d. per lb.	Again cheaper.
Bourbon Geranium Oil	36s. 6d. ,,	
Camphor Oil	75s. per cwt.	
Cananga Oil Java	10s. 6d. per lb.	
Cinnamon Oil, Leaf	6½d. per oz.	
Cassia Oil, 80/85%	8s. 9d. per lb.	
Citronella Oil—Java 85/90%	5s. 8d. per lb.	
Citronella Oil—Ceylon	3s. 7d. per lb.	
Clove Oil	8s. per lb.	Firmer.
Eucalyptus Oil 70/75%	2s. 1d. per lb.	
Lavender Oil—French 38/40% Esters	30s. per lb.	Very firm. Higher price expected owing to bad crops.
Lemon Oil	3s. per lb.	
Lemongrass Oil	3d. per oz.	
Orange Oil, Sweet	13s. per lb.	
Otto of Rose Oil—Bulgarian	37s. 6d. per oz.	Production below average.
Otto of Rose Oil—Anatolian	18s. per oz.	
Palma Rosa Oil	18s. per lb.	Cheaper.
Peppermint Oil—Wayne County		Firm spot and forward.
Peppermint Oil—Japanese	16s. per lb. nominal.	Market rising rapidly.
Petitgrain Oil	9s. 3d. per lb.	
Sandal Wood Oil—Mysore	26s. 6d. per lb.	
Sandal Wood Oil—Australian	21s. per lb.	

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before October 28th they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on September 11th.

I.—Applications

Broadley. Drying, grinding, mixing, etc. machine 18,930. Aug. 9.

Carlino. Means of pulverising and separating cereals, minerals, etc. 18,921. Aug. 9.

Loew. Filters. 18,711. Aug. 6.

Sterling. Apparatus for treating vapours from plants employing a gaseous heating medium. 18,689. Aug. 6.

I.—Complete Specifications Accepted

15,563 (1923). Dredge. Heating ovens for baking, roasting, drying and like purposes. (219,778.)

16,387 (1923). Fisher, Humphries and Co., Ltd., and Hutchinson. Rotary drying-cylinders. (219,787.)

16,861 (1923). Soderlund, Boberg, Testrup and Techno-Chemical Laboratories, Ltd. Drying processes and apparatus. (219,792.)

II.—Applications

Brooke. Gas-purifiers. 18,756. Aug. 7.

Bunge. Coke-oven installations. 18,610. Aug. 5. (Ger., 6.8.23.)

Jackson (Koppers Co.). Coking-retort ovens. 18,748. Aug. 6.

Kohlenscheidungs Ges. Distilling bituminous substances at a low temperature. 18,716. Aug. 6. (Ger., 24.11.23.)

Minerals Separation, Ltd., and Wood. Manufacture of fuel briquettes. 18,750. Aug. 6.

Soc. l'Air Liquide. Purification of coke-oven gases etc. 18,793. Aug. 7. (Fr., 17.11.23.)

II.—Complete Specifications Accepted

2892 (1923). Moore and Hunter. Apparatus for manufacture of combustible gas or gases. (219,471.)

11,602 (1923). Becker. Coking retort ovens. (211,817.)

11,633 (1923). White (Aero Pulverizer Co.). Methods and apparatus for pulverizing coal or other fuel and feeding it for combustion. (219,739.)

14,871 (1923). Habets. Method of improving coke as fuel for stoves and the like. (219,772.)

17,768 (1923). Humphreys and Glasgow, Ltd. (Gartley and Evans). Means for controlling or operating water-gas apparatus. (219,805.)

19,941 (1923). Pehrson. Method of and apparatus for the distillation or gasification of combustible materials. (202,625.)

30,169 (1923). Moore and Hunter. Method of and apparatus for manufacturing combustible gas or gases. (219,865.)

30,170 (1923). Moore and Hunter. Method of and apparatus for manufacturing combustible gas or gases. (219,866.)

III.—Application

Kohlenscheidungs Ges. Refining tar. 18,717. Aug. 6. (Ger., 28.11.23.)

IV.—Complete Specifications Accepted

23,348 (1923). Johnson (Badische Anilin und Soda Fabrik). Manufacture and production of vat colouring matters. (219,830.)

26,037 (1923). Soc. Anon. des Matières Colorantes et Produits Chimiques de Saint-Denis, Wahl and Lantz. Manufacture of naphthoquinone derivatives. (206,142.)

27,069 (1923). Imray (Soc. of Chemical Industry in Basle). Manufacture of a new azo dyestuff. (219,846.)

V.—Complete Specifications Accepted

20,406 (1923). Hondrich. Solutions for waterproofing porous materials. (219,818.)

6100 (1924). Marks (Naamlooze Vennootschap Hollandsche Kunstzijde Industrie). Process for preparing artificial silk. (219,898.)

VI.—Applications

Mycock. Apparatus for treating fabrics with liquor. 18,936. Aug. 9.

Toggin. Dyeing, scouring, etc. yarns. 18,937. Aug. 9.

VI.—Complete Specifications Accepted

13,809 (1923). Lord. Dyeing, washing, scouring, bleaching or impregnating of skeins or hanks of yarn. (219,768.)

14,377 (1923). Hohenloher Seifenfabriken Akt.-Ges. Process of washing and cleaning fabrics and other materials. (198,681.)

VII.—Applications

Llewellyn, Spence and Spence and Sons. Treatment of aluminous materials. 18,656. Aug. 6.

Sheffield. Manufacture of salt. 18,544. Aug. 5.

VII.—Complete Specifications Accepted

8956 (1923). Verein für Chemische und Metallurgische Produktion. Processes for the manufacture and production of pure sulphuric acid. (195,960.)

20,132 (1923). Jucker und Co. Chemische Fabrik. Recovering chromic salts from residues containing chrome. (201,942.)

VIII.—Applications

Ekert. Process of producing glass and porcelain ware. 18,601. Aug. 5.

Feldenheimer. Process for improving colour etc. of clays. 18,837, 18,838. Aug. 7.

IX.—Complete Specification Accepted

20,406 (1923). Hendrich. *See* V.

X.—Applications

Carline. 18,921. *See* I.

Ekert. Alloys for bearings etc. 18,602. Aug. 5.

Harris. Treatment of molten metals or alloys for separation or purification purposes. 18,919. Aug. 8.

Kratky. Cerium alloy. 18,966. Aug. 9.

Penner. Aluminium solder. 18,823. Aug. 7.

X.—Complete Specifications Accepted

5885 (1923). Marks (American Smelting and Refining Co.). Process of producing metallic tin. (219,719.)

12,091 (1923). Chemische Fabrik Griesheim-Elektron. Method of casting magnesium or magnesium alloys. (219,753.)

XI.—Application

Hartman. Ozone generator. 18,701. Aug. 6.

XI.—Complete Specifications Accepted

16,315 (1923). Fullers United Electric Works, Ltd., and Fuller. Galvanic batteries. (219,785.)

28,853 (1923). Reinhardt et Cie. Diaphragm for electrolytic processes. (207,801.)

XIII.—Applications

Campbell and Lloyd. Manufacture of white lead. 18,914. Aug. 8.

Goldschmidt Akt.-Ges. Production of paints. 18,749. Aug. 6. (Ger., 9.8.23.)

Leadbeater and Towler. Manufacture of printing etc. inks. 18,942. Aug. 9.

XIV.—Applications

Bigger and Falls. Rubber substitutes. 18,977. Aug. 9.

Goldschmidt Akt.-Ges. Process of improving rubber. 18,802. Aug. 7. (Ger., 9.8.23.)

Naugatuck Chemical Co. Process for treating rubber. 18,815. Aug. 7. (U.S., 8.8.23.)

Naugatuck Chemical Co. Process for retarding deterioration of rubber etc. 18,825. Aug. 7. (U.S., 8.8.23.)

Wills. Vulcanisation of rubber. 18,794. Aug. 7.

XIV.—Complete Specifications Accepted

11,249 (1923). Russell. Vulcanisation of rubber. (196,924.)

11,962 (1923). Warren. Method of and means for producing metallic surfaces on rubber compounds containing sulphur. (219,749.)

27,765 (1923). General Rubber Co. Processes and apparatus for concentrating rubber latex and similar materials. (218,965.)

27,992 (1923). Luff and North British Rubber Co., Ltd. Method for the production of decorative or other effects in vulcanised rubber. (219,853.)

XVI.—Application

Dosch and Smith. 18,615. *See* XIXB.

XVII.—Complete Specification Accepted

24,920 (1923). Hamburger and Kaesz. *See* XVIII.

XVIII.—Complete Specification Accepted

24,920 (1923). Hamburger and Kaesz. Process for the preliminary treatment of molasses for use in the manufacture of yeast. (209,034.)

XIXA.—Application

Carline. 18,921. *See* I.

XIXB.—Applications

Bock and Spearing. Apparatus for softening water. 18,969. Aug. 9.

Dosch and Smith. Nicotine substitutes for insecticides. 18,615. Aug. 5. (Canada, 8.2.24.)

Wayne Tank and Pump Co. Water-softening apparatus. 18,616. Aug. 5. (U.S., 4.4.23.)

XX.—Applications

Ransford (Cassella und Co.). Manufacture of 4-amino-3-oxybenzene-1-arsinic acids. 18,739. Aug. 6.

Ransford. Manufacture of arsinic acids of the aromatic series. 18,740. Aug. 6.

XX.—Complete Specification Accepted

17,390 (1923). Farbwerke vorm. Meister, Lucius und Brüning. Manufacture of carboxylic-acid chlorides. (200,511.)

XXI.—Application

Leirg, Pokorny and Ross. Colour photography. 18,907. Aug. 8. (Austria, 9.8.23.)

XXI.—Complete Specification Accepted

25,465 (1923). Schapovaloff. Photographic printing-process for the production of coloured images. (205,501.)

XXII.—Application

Unger. Safety explosives. 18,715. Aug. 6. (Sweden, 18.8.23.)

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department, and quoting the specific reference number:—*Belgium*: Medical and pharmaceutical supplies, Industrial chemical products (189); *Belgian Congo*: Iron and steel, Hollow-ware (A.X./1239); *Beyrout* (*Syria*): Silk yarns, skins (207); *British India*: Portland cement, metal (Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E. 1); Iron and steel (Directors of the Madras and S. Mahratta Railway Co., Ltd., 25, Buckingham Palace Road, Westminster, London, S.W. 1); *British West Indies*: Silk (185); *Denmark*: Pig iron, steel (192); *Egypt*: Leather (B.X./1142); *France*: Copper sulphate (193); *Italy*: Hides, metal (197); *Jugoslavia*: Tin (198); *Mexico*: Cement (213); *Nether-*

lands: Hides (202); *New Zealand*: Hardware (188); *Sweden*: Tinplate (206); *United States*: Rubber (209); Leather (B.X./1156); *Uruguay*: Iron (A.X./1237); Paper (B.X./1161).

Dystuffs (Import Regulation) Act, 1920

The following statement relating to applications for licences under the Dyestuffs (Import Regulation) Act, 1920, made during July has been furnished to the Board of Trade by the Dyestuffs Advisory Licensing Committee. The total number of applications received during the month was 515, of which 316 were from merchants or importers. To these should be added 35 cases outstanding on July 1, making a total for the month of 550. These were dealt with as follows: —Granted, 363 (of which 330 were dealt with within seven days of receipt); Referred to British makers of similar products, 135 (of which 106 were dealt with within seven days of receipt); Referred to Reparation Supplies available, 40 (all dealt with within two days of receipt); Outstanding on July 31, 1924, 12. Of the total of 550 applications received, 476 or 87 per cent. were dealt with within seven days of receipt.

Nickel in South Africa

According to the *South African Journal of Industries* a sedimentary bed has been discovered carrying a nickel ore of up to 25 per cent. The bed is up to three feet in thickness, and though not yet developed appears to be permanent in character. The ore seems to occur in the form of an entirely new mineral —a magnetic iron-nickel oxide. Sulphur is absent, and the mineral reduces easily, running down into a metallic button carrying about 54 per cent. nickel. If the deposits open up well, this mine should prove valuable.

Chemists and Students of Chemistry in Germany

The number of chemists employed by industrial concerns in Germany increased from 3089 in 1913 to 3781 in 1923, and 4010 in 1924. The number of students is 6·5 per cent. less in 1924 than in 1923.

Canadian Trade Notes

The E.B. Eddy Co., Hull, Que., is expending $2,000,000 in increasing the capacity of newsprint plant and reconstruction of sulphite pulp mill. The newsprint paper output will be increased from 50 to 100 tons per diem.

Arrangements are being made for the erection of a sugar beet factory in the Red River Valley, Manitoba. It will have a capacity of 18,000 tons of sugar. The beets will be obtained from 6000–8000 acres of land. H. C. Miller, of Denver, Col., one of the leading consulting engineers of U.S.A., who is connected with a well-known engineering firm specializing in beet sugar plants, has made a careful survey of proposed locations.

Australian Union of Chemists

According to the *Chemical, Mining and Engineering Review*, the Munitions Supply Chemists and Physicists' Association has applied for registration under the Commonwealth Arbitration Act. Membership is restricted to persons (1) employed under the munitions supply board as chemists, metallurgists or physicists, or in any administrative post, (2) possessing at least the British degree of B.Sc. in chemistry or physics, and association of the Australian Chemical Institute or its equivalent.

VOL. 43 NEW SERIES — LONDON, AUGUST 29, 1924 — No. 35

EDITORIAL

IT has become so much a habit to inveigh vaguely against the causes of atmospheric pollution that one turns with a certain feeling of relief to Dr. Owens' sober statement on the automatic measurement of impurity in air. Dr. Owens records some curious facts. It could have been prophesied that he would find, almost invariably, a maximum of smoky haze on Mondays, with the revival of industrial activity after the weekend, but it is strange that at Kew, where the haze is distributed with uniformity over the week, there should be a maximum on Wednesdays, just as at Westminster Bridge, and at Blackburn. Again, in the Potteries, there is a maximum on Mondays, with a steady decrease until Sunday. For the cause, one must examine the industries of the district. Our readers, safe on holiday in Folkestone or Abernethy, Looe or Elgin, will feel but remote interest in the smoke problem, though only too ready to express opinions, hot and strong, about the rain. Yet it has been suggested that rain is formed by the condensation of water vapour on smoke particles suspended in the air. Dr. Owens remarks that air pollution will not be prevented until the public demands purer air. People have, however, become accustomed to smoky skies and this is the cause of the psychological problem that troubles Dr. Owens. If he can convince the public that there is a definite connexion between smoke and rain, he will not lack support.

The article which we publish on the state of the resistance-glassware industry deserves close attention. Apparently, British-made laboratory glassware is satisfactory in every respect and the price is less than that of similar wares made abroad, but we are told that British makers are gradually being squeezed out of the market. The reason for this regrettable situation is that the cost of British glassware of first-class quality is compared with that of inferior products imported from the Continent. As a result the inferior and cheaper article is purchased in preference. It would thus appear that first-class laboratory ware is not always wanted and that there are laboratories content with inaccurately graduated flasks and pipettes, with non-resistant beakers and containers, in short, material which cannot yield accurate results. If this conclusion is correct—and no other can be reached, judging from the article, it is indeed surprising. We are accustomed to think of the extreme care with which chemists work and the close scrutiny that they apply to every possible source of error. But, it seems that untrustworthy glassware is being used, since the British-made, accurate ware is being replaced by it. We cannot think that chemists will accept the implication and we hope that our readers will send us their views for publication.

The Soda Deposits of Lake Magadi are described in this issue. Their recent history is of interest: the deposits have been worked for several years by an enterprising company backed by strong financiers: nevertheless, the results have been disappointing to the shareholders. Messrs. Brunner, Mond and Co., Ltd., who are now acquiring these deposits, will be able to bring considerable technical experience and a world-wide organisation with them The importance of such natural deposits may be expected to increase every year. Not only soda, but all mineral deposits become increasingly valuable not so much because of the reduction in supply, but because of the increased demand resulting from a more numerous and more highly-civilised population in the world. We may see the same tendency in coal, in metallic ores, in clays and rocks. The world requires more of everything, and many deposits which at the present time cannot be worked at a profit will in twenty or fifty years be valuable properties. Some day we shall watch the erection of a huge evaporating plant for the conversion of the Dead Sea into various crystals of soda and potash salts: some day the London clay will be used as a source of aluminium; some day granite will be too valuable to use as a building stone. We may see the beginning of this tendency; our grandchildren will see it clearly.

THE AUTOMATIC MEASUREMENT OF ATMOSPHERIC POLLUTION *

By Dr. JOHN S. OWENS

The measurement of the degree of pollution of city air by smoke is one of the essential steps towards improvement, which usually follows a desire to better conditions realised to be bad. Thus whatever technical means are available for reducing the degree of pollution of the air they will not be put into operation—unless where a definite economy can be shown by their use until there is a demand on the part of the public for purer air. Such a demand would follow a full realisation of the extent to which our cities now suffer from this evil, and of its injurious effects, especially in cutting off sunshine.

The author has given much attention to the provision of means for measuring the degree of pollution of the air, partly because he felt that lying behind the technical problem was the psychological one hinted at above. Up till 1912 there were no reliable data on the degree of pollution of the air of different cities. Thus few cities would acknowledge that their air was badly polluted; they usually pointed towards some other city as being worse. At the International Conference on Smoke Abatement in London in 1912 the author put forward a resolution to the effect that little progress would be made in the prevention or reduction of smoke until some accurate data could be obtained as to its quantity, and suggested the appointment of a Committee to investigate this. A Committee was appointed at the meeting and from this has developed the present organisation termed "The Advisory Committee on Atmospheric Pollution" operating under the Air Ministry, collecting data showing the relative purity of the air of different cities, and generally investigating the subject.

While the more simple method of measuring deposit from the air was adopted as being immediately available it was realised that deposit told only a part of the story, since there remained behind the suspended impurity in the air. A method of measuring this was therefore worked out by the author, and in 1916 a single record instrument was devised in which two litres of air were filtered through a disc of filter paper, ¾ in. diameter, and the resulting discoloured spots obtained compared by means of a calibrated scale of shades. In 1917-18 this method was further developed into the automatic recording apparatus which is the subject of this paper. These instruments are fully described in the Third and Fourth Reports of the Committee.

The automatic recorder is primarily designed for measurement of smoke pollution in city air. The principle is similar to the single record instrument referred to, but in this case a large circular disc of thick filter paper, divided into 24 hours, is caused to revolve by a clock, while at intervals a small disc of ⅜ in. diameter is isolated near the edge of the filter paper by the pressure of a perforated plug, and through this disc two litres of air are automatically aspirated, leaving behind on the paper the impurities filtered out, which, since in cities they are mainly due to smoke, are practically black.

The interpretation of the results calls for a special scale of shades; such was made and numbered 1, 2, 3, 4, 6, 8, 10, 12, 15, 20. The scale was made by laying on successive washes of a standard lamp-black suspension on white paper, the number of washes being indicated by the number of the shade. Thus the scale became a linear one of quantity of impurity: Shade 2 indicating twice as much as Shade 1, and so on. Small perforations in the middle of each permitted the record to be examined surrounded by the shade to be compared with it. The values of the different numbers were obtained experimentally by weighing large discs through which known volumes of city air had been passed. In this way a numerical value could be given to the records in milligrammes of impurity per cubic metre, and having obtained a numerical value the comparison of different places and times became a simple matter.

Having obtained a number of records from such an instrument over a long period, say one year, the numerical values, either in shade numbers or milligrammes per cubic metre, are tabulated, and in this tabulation the days are divided into three groups—ordinary weekdays, Saturdays and Sundays. This is done because the conditions governing smoke production remain much the same between Monday and Friday, whereas on Saturdays factories usually work for half a day, while on Sunday they are mostly shut down. From such tables averages for a large number of days are prepared, so that curves may be plotted showing the average distribution of impurity over the 24 hours for each of these groups, and for different places, and a study of such curves brings out the relation between smoke pollution and human activities, often pointing to the chief sources.

In many cities where large quantities of smoke are produced, thick smoke hazes are not unusual; these do not arise from abnormal smoke production at the time, but from failure of the natural processes by which the normal smoke is removed as produced. Such failures usually occur during anti-cyclonic weather with very light, indefinite winds and an inversion of the temperature gradient, which prevents the escape upwards of the smoke.

In plotting curves obtained from the automatic recorder it was, therefore, found advisable to divide the days into two groups:—

Those in which, owing to some abnormal atmospheric conditions, the smoke haze was at some time very thick; designated "Days of much smoke haze" and referred to in what follows as "Z days," and

Those in which the smoke haze was not at any time abnormally thick; designated "Days of little smoke haze" or "ordinary" days.

This division is necessarily arbitrary, and the limit dividing the two was fixed at days having a maximum impurity at any time up to or over Shade 4—equivalent to 1·28 milligrammes per cubic metre.

The division adopted is therefore into days symbolised by:—"Z" or days of much smoke haze, and

Days of little smoke haze (not ranking as "Z").

* Paper read before Section A. (Mathematics and Physics) of the British Association at Toronto.

It is to be understood that variations in thickness or density of the smoke haze from day to day are usually determined more by atmospheric conditions than by changes in the rate of smoke production.

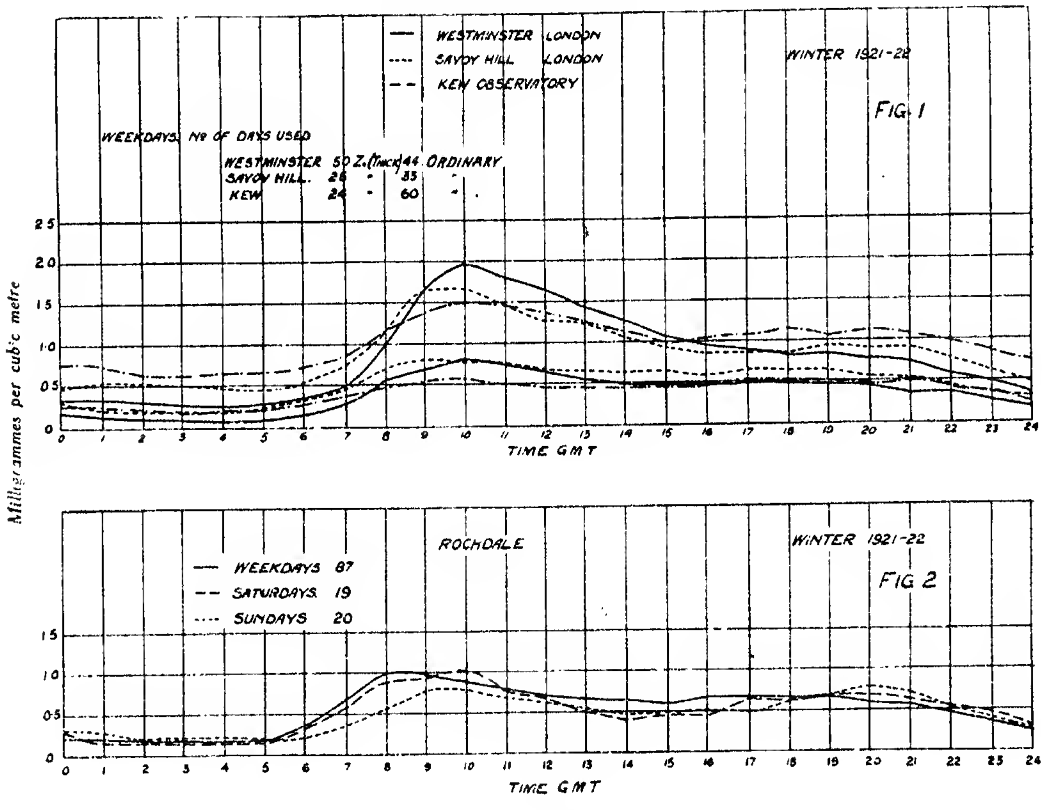
It will be of interest now to compare a few of these typical curves for different cities. It is evident that the distribution of quantity of impurity present in the air must depend upon the times and quantities of smoke emission. Thus industrial cities and residential cities would be expected to show considerable differences. Similarly the nature of the industry carried on must influence the result.

Curves are shown for London, as a mixed residential and manufacturing city, Rochdale, Blackburn, Glasgow and Stoke-on-Trent.

second but lower maximum, while at about 10 p.m. it rapidly falls away until about midnight again. This is quite typical of the London distribution. The Sunday curves are similar but the maximum is not reached in the forenoon until an hour or two later. There is no doubt that the rise between 6 and 7 a.m. starts from the lighting-up of fires, which make the greatest quantity of smoke soon after lighting. When fires are well established the smoke is reduced; therefore we find the quantity falling off in the afternoon, while the custom of having afternoon tea is probably responsible for the rise about 4 to 5 p.m. The average weekday maximum in winter reached about 2 milligrammes per cubic metre in Westminster, 1·3 at Savoy Hill, and 1·5 at Kew for Z

London

Suspended Impurity in the Air



The London curves of impurity are for Westminster, Savoy Hill and Kew Observatory, which is situated at Richmond, about eight miles to the west of the centre of the City.

The curve for weekdays only is shown as this illustrates the distribution sufficiently.

Referring to Fig. 1, the impurity is seen to be at its lowest between midnight and 6 a.m., after which it rises rapidly to a maximum between 9 and 10 a.m., then falls steadily until about 4 o'clock in the afternoon, when there is a tendency to rise slightly to a

days, while for other days in Westminster and Savoy Hill the maximum averaged about 0·8, and Kew about 0·6 milligrammes per cubic metre. In the summer the quantity is reduced greatly, the maximum for Westminster being under 0·5 milligrammes per cubic metre.

In Fig. 2 the average for the winter impurity for each hour of the day is plotted for Rochdale, for winter days, and the curve is here shown to illustrate the similarity in the distribution with London. No separation of the Z days has been made here.

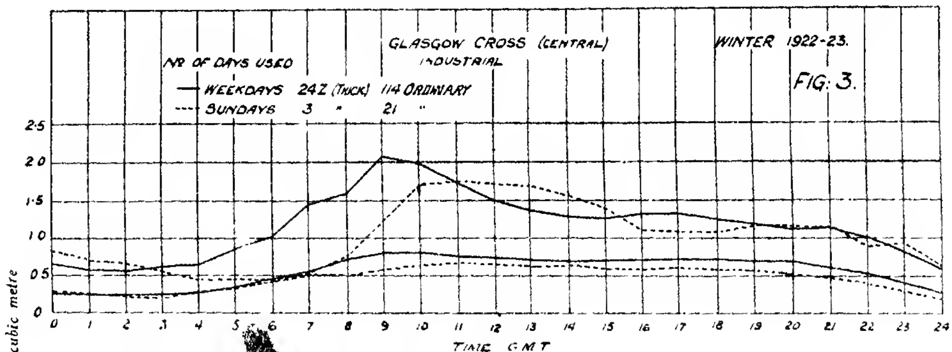
In Fig. 3 the curve for Glasgow Cross, an industrial district, is given for the winter 1922-23. The distribution over the 24 hours is very similar to that in London, except that the afternoon falling off for ordinary days is not so well marked, the impurity being maintained at a fairly high level until 8 to 9 p.m. The lag of one hour in the Sunday maximum is very well marked. Saturdays have not been separated from other weekdays here.

In all of these curves a large number of days have been averaged so as to get a curve fairly representative of the general distribution.

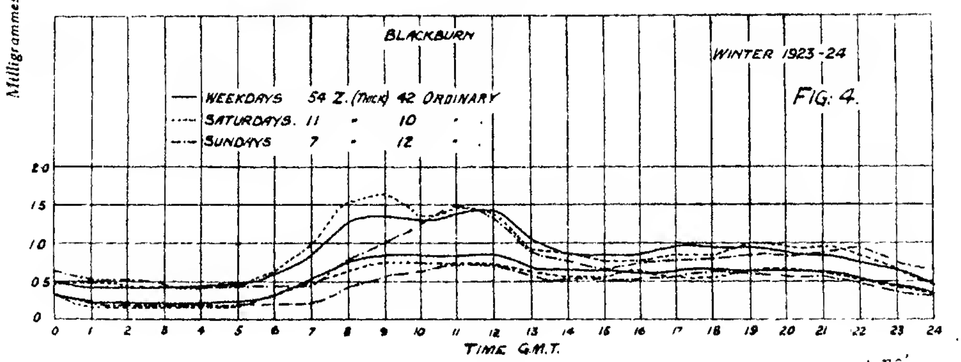
Curves for Blackburn are shown as they exhibit some departure from the type above referred to. These are prepared from records of 269 days of the year 1923-24, 136 being winter days—72 of which are ranked as Z, in the sense already defined. The curves themselves are somewhat smoother, indicatin steadier conditions. The distribution, however, h some important peculiarities of its own: for exampl the rapid rise of impurity in the morning commence in the summer about 4 a.m., and reaches its maximu on weekdays and Saturdays at 7 a.m., while o. Sundays the maximum is not reached until 10 a.n. Thus it would seem that the people of Blackburn are early risers on weekdays but take a long spell o Sunday mornings. Again, in the weekday an Saturday curves for both summer and winter there is a second maximum between 10 and 12 in the forenoon. This is particularly well marked in the winter curves (Fig. 4), where the second weekday maximum occurs at 12 o'clock on Z and ordinary days, and this is higher than the first maximum which occurs at 8 a.m. In both Z and ordinary weekdays the second maxi-

Glasgow

Suspended Impurity in the Air.



Blackburn



Referring to the curves in Fig. 4, the hourly distribution is broadly similar to that found in other cities, such as Glasgow and London. There is the same rapid increase in impurity rising to a maximum in the forenoon. There is then a gradual tendency to fall, followed by a subsequent rise to a second but lower maximum late in the afternoon.

The summer curve, not shown, indicates a uniformly lower impurity than the winter and the mum is higher than the first, and there is a four-hour interval between them. It would seem, therefore, that in Blackburn there are two main sources of smoke which make their maxima at different times. We get a clue to the position by examining the Sunday curves, which show no evidence of a double maximum in the forenoon. One is therefore inclined to conclude that the first maximum is due to industrial or factory furnaces and the second to dom... fires.

In support of this is the fact that while in the winter the second maximum is higher than the first for weekdays, in the summer the first is higher than the second. This fits in well with the theory that the second maximum is due to domestic smoke.

Another feature which is noticeable in the Blackburn curves is that the minimum impurity is not found until well after midnight, but this has been observed in other cities.

The Sunday curves fall in all cases below those for weekdays or Saturdays, indicating a greater purity of the air on Sundays due to suspension of factories. It is somewhat remarkable, however, that the curves for weekdays, Saturdays and Sundays lie very close together after the second maximum in the forenoon has been passed; the greatest difference in all cases is in the forenoon. This is particularly well marked in the Z winter days with thick haze.

The relation between the total smoke on Sundays and on weekdays is 2000 to 3077. This is based on the ordinary winter days, not ranking as Z, and if the Sunday smoke be assumed to be domestic while the weekday is domestic plus factory, the ratio of factory to domestic smoke becomes 1 : 1·85.

Stoke-on-Trent.

Stoke-on-Trent differs from the other cities in the nature of the industry carried on, which is mainly pottery; hence it is to be expected that the records would show marked peculiarities.

From Stoke-on-Trent there are records for a total of 222 days. Included in the records are 126 winter days, 82 of which were ranked as Z. Thus of the winter days recorded 65 per cent. had thick smoke haze, or, roughly speaking, Stoke-on-Trent appears to suffer from thick smoke haze on two out of every three days. This is perhaps not to be wondered at, as to prevent smoke in the pottery industry is most difficult.

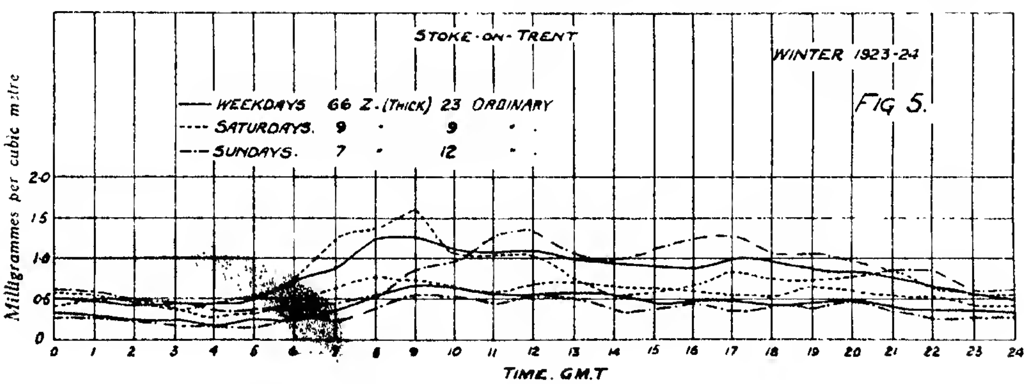
In Stoke the impurity begins to increase about 4 a.m. on weekdays and about 5 a.m. on Sundays. On summer weekdays and Saturdays a maximum is reached between 7 and 8 a.m., while in the winter on weekdays and Saturdays the maximum is somewhat later, between 8 and 9 a.m. On Sundays in the winter the maximum is delayed till about mid-day.

In both summer and winter the impurity is maintained at a high level during the whole afternoon, with remarkable oscillations, producing maxima at intervals during the whole afternoon. The impurity both in winter and summer does not decrease to any marked extent until about 10 p.m., and, as already mentioned, has its lowest value about 3 a.m.

Again, it is noticeable that the amount of impurity on ordinary winter Sundays is not markedly less than on weekdays, the ratio on Sundays and weekdays being 2022 to 2398. It is evident that here there are conditions which make it impossible to apply the method already used for ascertaining the relation between factory and domestic smoke as this method is based on a cessation of factory smoke on Sundays. The general inference one would draw from the curves for Stoke appears to be that the sources of smoke obey no general rule as to starting and stopping, and this is what might be expected when dealing with pottery kilns, the firing of which would not follow any strictly definite arrangement as to time, nor would the emission of smoke from such cease on Sundays.

There is definitely less smoke in the summer than in the winter as is shown by comparing the summer curves with those of the winter. This is doubtless due to the reduction in domestic smoke due to the warm weather.

A somewhat remarkable feature of all the Stoke curves for both summer and winter is the fact that in every case the Saturday forenoon maximum is the highest. This would be caused should there be a



Turning now to the curves in Fig. 5, there is a definite rise in each of the curves starting between 4 and 5 a.m. In each city, curves for which are shown, the minimum amount of impurity is about 3 a.m., while between midnight and about 6 a.m. the quantity does not rise much above the minimum referred to. This is therefore the part of the 24 hours which has the purest air.

custom of lighting kilns on Friday night or Saturday morning, and on enquiry this was found to be the case.

The incidence of atmospheric impurities on the different days of the week can be studied from these records, and it is found that there is a definite difference observable, already hinted at in the curves above referred to.

Table Showing for the Winter Months the Incidence of Thick Smoke Haze on the Different Days of the Week
That is, of days ranking as Z

In the accompanying table for six stations the total number of each of the days of the week available is given, that is the numbers of Mondays, Tuesdays, etc., for which there are records available, also the number of such days which rank as Z, as defined above, and finally a figure showing the percentage of Z days.

The results of the table have been plotted in Fig. 6, which brings out graphically the incidence of thick smoke haze.

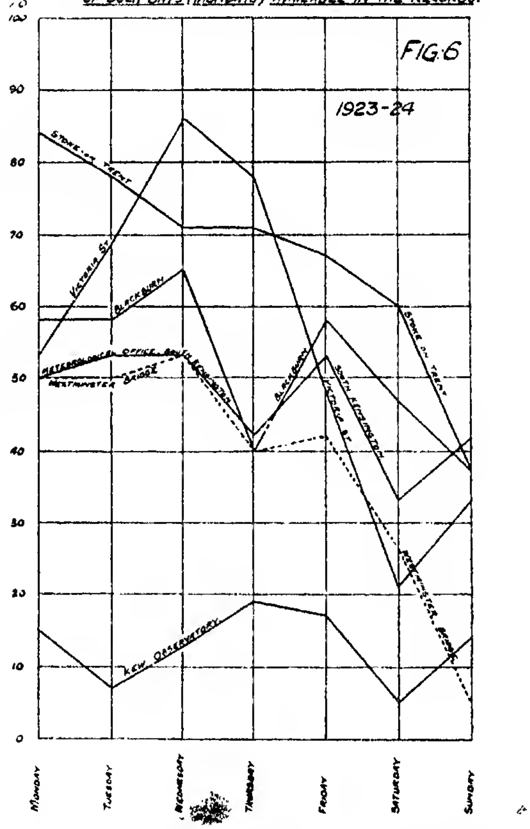
It is evident that there is a general tendency in practically all stations to a minimum of Z days towards the end of the week, and a maximum near the beginning. An exception to this rule is at Kew, which shows a slight maximum in favour of Thursday; in fact the days of thick haze are scattered comparatively uniformly over the week at Kew. In Victoria Street, Westminster, there is a maximum number of Z days on Wednesdays, with a minimum on Saturdays. At the Meteorological Office, South Kensington, there is a maximum on Wednesdays and Fridays, and a minimum on Saturdays. Westminster Bridge shows the same maximum on Wednesdays, but its minimum is on Sundays, the second lowest being on Saturdays. Stoke-on-Trent shows a maximum on Mondays and a minimum on Sundays, there being a practically steady fall during the week from Monday to the following Sunday. Blackburn has its maximum number of days with thick smoke haze on Wednesdays, and its minimum on Sundays.

Comparison Between Automatic Filter and Jet Dust Counter

The results obtained by the automatic recorder are based upon the discoloration of filter paper by the impurities filtered out of a measured volume of air. It was felt that, in cities the main source of impurity being smoke from burning coal, little error would be involved by taking this as black and basing the results on the degree of blackness of the paper.

Some test of the validity of this was advisable, however, and for this purpose it was compared with the results of another instrument devised by the author for enabling a microscopic count of the dust suspended in the air to be obtained, which count does not depend upon the colour of the particles. This latter instrument has been described fully elsewhere.* It depends for its action upon the projection of a narrow ribbon-shaped jet of air against a microscope cover glass at such a velocity that there is a marked fall of pressure, adiabatic expansion and cooling in the jet, resulting in condensation of the water present in the air upon the dust particles and upon the cover glass where the jet impinges. This results in the dust particles being projected against the cover glass by virtue of their greater density and their increase

CURVES SHOWING THE NUMBER OF THICK SMOKE HAZES (Z) FALLING ON A PARTICULAR DAY OF THE WEEK (SAY MONDAY) AS A PERCENTAGE OF THE TOTAL NUMBER OF SUCH DAYS (MONDAYS) AVAILABLE IN THE RECORDS.



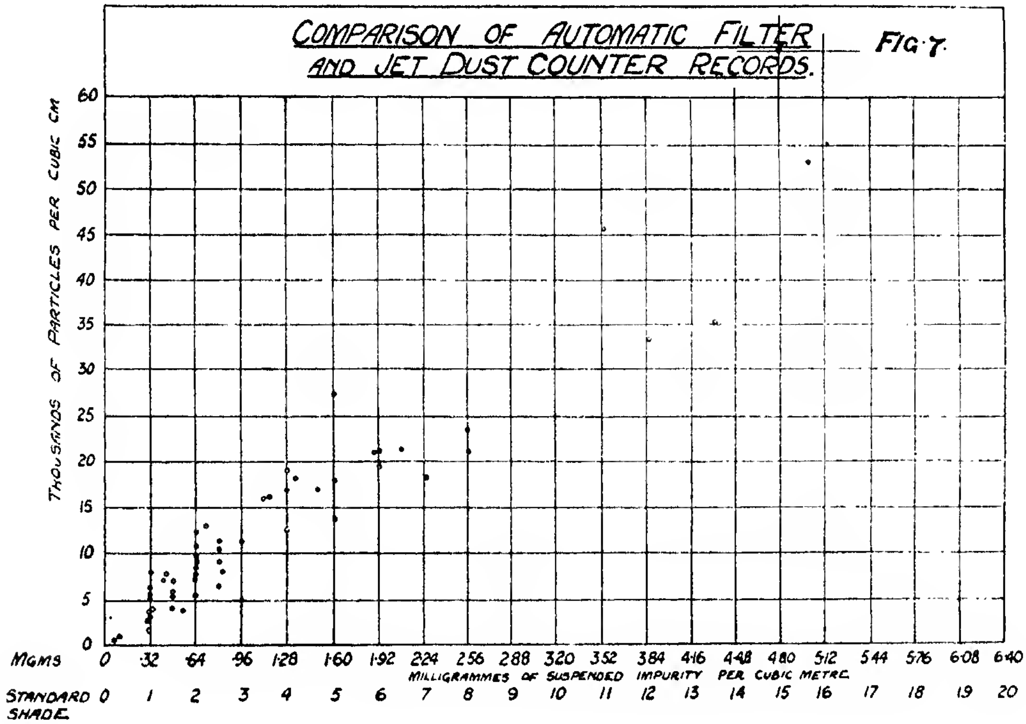
of mass due to condensed water. They adhere firmly to the glass, as the water evaporates immediately, leaving a linear track or record of dust. This track is examined microscopically, when the particles can be counted, measured and often identified.

In connection with the experiments being made for the Advisory Committee upon the obstruction of light by suspended matter in London a large number of simultaneous records have been taken both with

* Proc. Roy. Soc. A., Vol. 101, 1922.

the automatic recorder and the jet dust counter. The results of these records have been plotted in the form of a curve; the impurity, expressed in milligrammes per cubic metre, as obtained from the automatic recorder as abscissæ against the number of particles per cubic centimetre as determined by the jet dust counter. This is shown in Fig. 7.

gramme per cubic metre. It is not suggested here that this relationship will hold good for all types of dust as it obviously could not, nor is the automatic recorder, as originally designed, suitable for recording dust other than that produced by smoke. In particular cases of coloured smoke, such as that from refuse destructors, blast furnaces, metallurgical smoke and the like, the use of a suitably-colo ued filter paper would enable comparative records of impurity from such causes to be obtained.



Referring to the figure it will be seen that there is a reasonably constant relation between the number of particles per cubic centimetre, as determined by the dust counter, and the weight of impurity in milligrammes per cubic metre, as given by the automatic recorder. It is not to be expected that the relation would be absolutely constant as this would imply great constancy as to the size of particles at different times. While there is an evident tendency towards uniformity there is also definito departure from it, which is very evident during thick smoke haze. In such cases the average size of suspended particles is usually greater than during light haze, and this is probably due to the rapid accumulation of the smoke to form a thick haze which does not give time for settling out of the larger particles. Thus it is reasonable to expect that we shall find in rapidly formed smoke fogs larger particles than are normally present. The maximum diameter of smoke particles in the absence of thick smoke haze is about 1½ microns, while during thick smoke haze the maximum diameter rises to about 3 microns. Broadly speaking, however, the curve in Fig. 7 indicates that there is a constant relation such that in London approximately 10,000 particles per cubic centimetre correspond to 1 milli-

ELECTRICAL GAS PRODUCTION

Electrical gas production may prove a profitable proposition in those countries possessing abundant water power, by providing a use for the power output at night. Delicate temperature control is possible, and water-gas of a high degree of purity can be obtained. Fuels with high moisture and ash content could be utilised, the water being used for water-gas production and the hot ashes for raising steam. The purity of tho gas renders it very suitable for producing high temperatures, and for chemical reduction processes, as well as for its ordinary uses. With liquid fuels the advantages should be even more marked, largely on account of the temperature control, the cracking being thus regulated to facilitate fractionation of the products. In addition, the electrical apparatus has the advantage of long life.

THE SODA DEPOSITS OF LAKE MAGADI IN KENYA

The greater part of the World's supply of sodium carbonate is obtained by the chemical treatment of common salt, but in certain parts of the world there are natural deposits of sodium carbonate and bicarbonate which are worked. The deposit at Lake Magadi in Kenya Colony is the most notable, both as regards the extent of the deposit, and the purity of the material

In March, 1908, the Imperial Institute was consulted by the Colonial Office with reference to certain proposals then under consideration for the industrial development of the soda deposits of Lake Magadi, which lies in about the centre of the Rift Valley and not far from the border of Tanganyika Territory. The information available at the time was insufficient to show :—(1) whether the crust of soda on the surface of the lake was of uniform composition throughout, (2) the nature and extent of the underlying deposits on which the renewal of the supply of soda depended, and (3) whether there was any accumulation of residual impurities in the water present in the crust. It was decided that a further investigation should be directed to the valuation of the deposit, and this was undertaken by Mr. J. S. Coates, from whose report the following information has been extracted (*Bull. Imp. Inst.*, XXI., 3, 1923). The soda deposit covers the whole width of the trough for a length of 12 miles in the middle portion of the lake bed. Near the shore, the soda forms only a thin soft layer on the mud of the lake bottom, and is covered by a layer of liquor. At a distance of 200 yards from the shore, the soda crust had already a thickness of more than 6 feet. The crust was pierced by drilling in two places near the edge of the deposit and in neither case was any liquid substratum found, the soda lying in immediate contact with the mud of the lake bottom. The interstices and cavities, however, of the crystalline matter were filled with liquid. The density of the soda crust was estimated at about 76·4 lb. per cb. ft. Assuming a depth of 5 ft. of crust over an area of 22½ square miles—and this may be taken as a proved minimum—it follows that the amount of crude soda available is not less than 107,000,000 tons. Lake Magadi is therefore the largest known natural source of sodium carbonate.

Although it was shown by the analyses that the liquid from which this crystalline crust had separated contained in solution other salts, notably sodium chloride and sodium sulphate, the conditions were such that the separated crystals were practically pure trona, a mixture of carbonate and bicarbonate of soda or sesquicarbonate of soda ($Na_2CO_3.NaHCO_3.2H_2O$) which needed only to be freed by draining or washing from the adherent liquid to become a very pure material. A large number of hot springs arise along the margin of the lake, and discharge into it. The composition of these spring waters indicates that fresh supplies of sodium carbonate are being added constantly to the lake.

The technical side of the utilisation of the Magadi soda, at least in principle, would appear to be a very simple matter, since the crust after removal, merely requires draining, washing and roasting to convert it into soda ash (dry sodium carbonate) of a high degree of purity, which could be exported as such, or converted in Kenya into other sodium compounds required in commerce, such as caustic soda and soda crystals.

The following table gives :—(1) the average composition of Lake Magadi soda as computed from the thirteen analyses quoted in Mr. Coates' report ; (2) the probable average composition of soda ash made from Magadi soda ; (3) the average composition of commercial soda ash made : (*a*) by the Leblanc process, and (*b*) by the ammonia-soda process :—

	Magadi soda crust	Magadi soda ash	Leblanc soda ash	English ammonia-soda ash	Solvay soda ash
			Per cent.

From these results it would appear that soda ash made from Lake Magadi soda might be slightly inferior to soda ash of commerce in containing a larger quantity of sodium chloride, but it must be remembered that in collecting the samples no precautions were taken to remove the adherent and entangled mother liquors.

The exploitation of the Magadi soda deposit was undertaken by the Magadi Soda Co., Ltd., which was formed in 1911, and which undertook the construction of a branch railway line, 93 miles in length, from the deposit to the Uganda Railway, thus connecting it with the port of Kilindini on the coast. The company also undertook the building of a pier and the dredging of approaches at Kilindini. The soda is excavated from the lake by means of a dredger specially designed for the work. The soda works at Kiu on the shore of Lake Magadi are equipped with two calciners for converting the crude material into soda ash, of which it is estimated that an output of 8000 t. per month could be attained ; but so far, the production has been much below this amount owing to many adverse factors. Factories for the conversion of the calcined soda into caustic soda, soda crystals and other products have been erected at Budge-Budge near Calcutta, India, and at Irlam, near Manchester, England, but the latter does not appear to have been used so far. Works have also been built at Kilindini. The quantity of calcined soda, in long tons, exported from Kilindini has been as follows :—1916-17, 2163 ; 1917-18, 4688 ; 1918-19, 12,007 ; 1919-20, 10,544 ; 1920-21, 12,829. The destination of the exports in 1920-21 was as follows :—United Kingdom, 894 t. ; India, 3329 ; South Africa, 270 ; Tanganyika, 4 ; Zanzibar, 28 ; Norway and Sweden, 4771 ; Austria, 710 ; Japan, 2474 ; China, 302 ; and other countries, 47 t., making a total export of 12,829 t. (For recent information on the situation of the Magadi Soda Co, *cf. Chem. and Ind.*, pp. 100, 150, 287, 671, 859 ; 1924.)

HARD RESISTANCE GLASSES AND THE PROGRESS OF LABORATORY GLASSWARE

With the passing of the 10th anniversary of the opening of hostilities on the Continent, we are reminded of the importance then attached to the immediate production of scientific glassware to meet the needs of laboratories and medical and surgical organisations. At that date we were almost entirely dependent on foreign supplies and much preliminary work had to be undertaken before manufacture could be started. It was found that Jena glass, which had come to be the accepted standard quality, was a zinc-sodium-aluminium borosilicate, whereas Kavalier's glass, almost as well known, was a calcium-potassium-sodium silicate. The latter, however, was less resistant and consequently development proceeded on the lines of Jena glass, the main object in view being chemical resistance combined with a reasonable resistance to heat shock.

As an outcome of investigations by individual manufacturers and the Glass Research Committee of the Institute of Chemistry, glasses similar to Jena glass were evolved and produced on the manufacturing scale, with the additional advantage, in the case of one at least, that it was adaptable for blowpipe work and platinum could be sealed in direct; its chemical resistance also was superior to any previously observed. These glasses were put into use for beakers, flasks, and other ware, whilst another glass of simpler composition, high in lime and alumina, with the exclusion of zinc, was employed for ampoules, for which neutral glass was required with good working properties in the blowpipe. Such glasses fulfilled immediate requirements and were in constant demand until the Continental supplies again became available.

The defects of the British-made glasses were then apparently more prominent and criticism was adverse in anticipation of better foreign supplies being forthcoming, a hope, however, which was not fulfilled except as regards price, and in the meantime improvements were being made, with the result that a superior British glass was placed on the market which retained to a great extent its resistance properties, but had an appreciably higher thermal endurance. Progress in America in the production of laboratory glassware proceeded on similar lines, the outstanding product having high resistance to heat shock, associated with a reasonable resistance to chemical attack.

This demand for better glass, necessitated greater expenditure on materials, and even more efficient furnace conditions for melting, all conditions which added to the cost of production.

A pre-war miner's lamp glass was held to be satisfactory if it withstood the test of being heated for 20 minutes in boiling water, and then plunged into water at 15° C. without fracture. Such glasses are sodium-potassium borosilicates with a high percentage of boric oxide, chemical resistance being of secondary importance. The best of the pre-war laboratory glasses failed when chilled from temperatures of 160°—200° C., under similar conditions, whereas the latest improved types have a thermal endurance of at least 220°—250° C., and under certain conditions even higher. Far greater reliability has thus been secured, and British-made glasses cover all requirements in this direction.

These improvements in heat resistance led to the application of laboratory glass for illuminating purposes and there are now five firms manufacturing laboratory glassware in Great Britain, and at least two others producing heat-resistant glass for gas globes, miner's lamp glasses, and the like, all suffering from over-production on the one hand, and unrestricted imports on the other.

Some idea of the variation of prices of eight common patterns of laboratory apparatus, taken from a standard catalogue, may be gathered from the following table :—

	1914 s. d.	1920 s. d.	1922 s. d.	1923 s. d.	% Increase
Beakers, squat 250 c.c. ..	4 4	8 6	12 0	10 3	143
,, ,, 400 c.c ..	5 9	10 6	15 0	12 9	122
Flasks F.B. 500 c.c. ..	6 3	12 0	16 6	14 0	124
,, ,, 1000 c.c. ..	9 0	20 0	27 0	23 0	155
,, R.B. 700/750 c.c. ..	7 6	17 0	23 0	19 6	160
,, Conical 200 c.c. ..	3 3	8 6	12 0	10 3	210
,, Extraction 200/250 c.c.	4 6	10 6	12 0	12 0	166
,, Kjeldahl L.N. 500 c.c.	7 3	18 0	25 0	25 0	246

Certain anomalies are noticeable when considering these increases, which arise from the fact that the 1914 prices include freight from the Continent, which in turn depended to a great extent on the manner in which the various patterns lent themselves to close packing, whilst changes since 1920 reflect the influence of costs on selling prices, these being governed by the difficulties of manufacture and the proportional demand. These increases may appear excessive, but are far less than the same increases which have occurred with Jena glass itself, the original 1914 prices of which have already been given above.

	1923 s. d.	% increase
Beakers, squat 250 c.c.	19 6	350
,, ,, 400 c.c.	24 0	320
Flasks F.B. 500 c.c.	20 0	220
,, ,, 1000 c.c	32 0	255
,, R.B. 700/750 c.c.	25 6	240
,, Conical 200 c.c.	12 8	290
,, Extraction 200/250 c.c. ..	16 8	270
,, Kjeldahl L.N. 500 c.c. ..	28 8	300

Best quality Bohemian resistance glass, of which the ingredients are less expensive, is from 15 to 20 per cent. less than the current British prices, whilst inferior qualities of laboratory glass are on the market at prices considerably less than these, in some cases less than half the British prices.

The question of price of laboratory supplies is often the prime consideration and although the British glassware has properties equal to that of the best, the cost is always compared with the common varieties of Continental origin. The figures recall the fact that, whereas the British product is competing satisfactorily both in quality and price with similar goods from abroad, it cannot compete with the articles dumped here, bearing no mark or

other certificate of origin. Every British manufacturer brands his goods, and guarantees their quality, but in spite of this, he is slowly being squeezed out of the market.

The same remarks apply to illuminating glass. Many of the gas globes obtainable from the usual sources of supply are merely common flint-glass, or an inferior resistance glass. The general public does not purchase the best quality, in fact very few facilities are offered by either the wholesale or retail trade to enable it to do so. Consequently, we read that British illuminating glass is unobtainable except at excessive prices, whereas the British manufacturers' price is approximately equal to the wholesalers selling price for the foreign glasses costing probably one-third or less than this.

Heat-resistant glasses recently placed on the market are reported to contain titania and zirconia, suggesting that higher thermal endurance necessitates higher cost of production.

Satisfactory combustion tubing has been supplied which is a soda-lime-alumina borosilicate, with a small proportion of potash. Demands for tubing suitable for blowpipe work have been adequately met and prices are low. This is a potash-soda-lime glass, also suitable for X-ray bulbs. The need for hard glasses suitable for sealing rare metals such as molybdenum and tungsten has been met, as also for glasses for high power thermionic valves.

The standardisation of laboratory glass has been effected to a limited extent, beakers and flasks receiving attention, and the bulk of the manufacturer's patterns conforms to these standards. In spite of this, however, flasks are still required to fit corks and beakers and to fit water baths of old origin, to quote only two examples. Lampblown ware, such as condensers, fractionating columns, of known design, although most suitable for standardisation have yet to be dealt with.

Volumetric glassware is subject to keen competition by reason of surplus stocks from the Continent. Accuracy in this case is of secondary consideration, although the value of a graduated vessel with uncertain errors is hard to conceive. In 1921, under the auspices of the N.P.L., "Commercial Grade" volumetric glassware was introduced by the British manufacturers, unstamped, but carrying their trade name and guaranteed to be within the Class B tolerances. This, however, is only in limited demand, as graduated flasks of unknown origin and accuracy are obtainable at less than half the price, while the difference with pipettes is even greater still, 50 c.c. at 12s per dozen being one-third the price of Class B quality guaranteed. Higher standards are also procurable from reliable manufacturers, accompanied either by their own certificates or by one supplied by the N.P.L. The methods of calibrating have been almost perfected, although there is still considerable room for improvement in the dividing machines, the bulk of which are slow and cumbersome.

The capacity of the country for the production of laboratory glass and resistance glass of all descriptions is now fully organised, but the future depends largely on the general trade of the country, and the recognition of the superior properties and reliable service of the British product. It is the Master Key Industry. Is it destined only to become a memory of the past?

SMOKELESS FUEL

The Pure Coal Briquette Process: An Important Development

(From a Correspondent)

The members of the Society of Chemical Industry are familar, because of the various papers that have been read on the subject before the Society during the past few years, with the important part played by structure in the production of smokeless fuels by the carbonisation of bituminous coals. It is, of course, well known that to combine smokelessness with free ignition we can either partially decompose the volatile matter by low-temperature carbonisation, leaving about one-third in the residual fuel, or submit the coal to relatively high temperatures in such a manner that the residual fuel is extremely close-grained and cellular, resembling charcoal, and quite different from ordinary gasworks or metallurgical coke. The best example of this latter method is the Pure Coal Briquette carbonisation process, and considerable interest attaches to the statement recently made that Messrs. Sutcliffe, Speakman and Co., Ltd., of Leigh, who control this process, have now solved, after over five years work, the difficult mechanical problems of the 10-ton high duty briquette press necessary.

It will be remembered that the essential principles involved are the mixing of 80 per cent. roughly crushed coal with 20 per cent. coke breeze, and the briquetting of this non-swelling mixture at the enormous pressure of 10 tons per square inch so as to give a hard briquette without pitch or other binder, forming "pure coal" briquettes. These are then carbonised at relatively high temperatures of 1650° F., and as they have the great advantage that they do not soften, expand, or alter their shape, simple continous retorts of huge capacity up to 500–1000 t. can be used with internal heating. In this way are obviated some of the great difficulties of many low-temperature processes, low throughout, small and intricate retorts, and intermittent operation. Also the fact that only 1 per cent. of volatile matter is left in the fuel means that, whilst it is perfectly free burning, for the same reason as charcoal, all the volatile matter has been decomposed into valuable products, and one-third of it is not left to be burnt as mere fuel, as happens with ordinary low-temperature processes. That is to say a very high yield of gas, 10,000 cubic feet per ton, and of sulphate of ammonia, 40 lb., is obtained in addition to purely paraffinoid liquid products. Finally, because of the combined blending, briquetting, and subsequent carbonisation the product is so hard that it is superior to metallurgical coke, and the possibilities of the Pure Coal Briquette carbonisation processes are important, not only to the iron and steel industries, and for the operation of the blast furnace, but also, from the national point of view, for the production of solid smokeless fuel to replace coal for all purposes, liquid fuel, and sulphate of ammonia.

FORTHCOMING EVENTS

Sept. 1. INSTITUTION OF THE RUBBER INDUSTRY, *London Section*, The Engineers' Club, Coventry Street, Piccadilly, W., at 8 p.m. "The Acidity of Raw Rubber," by Dr. G. Stafford Whithy.

Sept. 4 and 5. IRON AND STEEL INSTITUTE, Autumn Meeting at British Empire Exhibition, at 10.30 a.m. each day. (1) "Changes of Volume of Steels During Heat Treatment," by L. Aitchison and G. R. Woodvine. (2) "Investigations on the Herbert Pendulum Hardness Tester," by C. Benedicks and V. Christiansen. (3) "Effect of Changes in Total Carbon and in the Condition of Carbides on the Specific Resistance and on some Magnetic Properties of Steel," by E. D. Campbell and G. W. Whitney. (4) "Pickling: The Action of Acid on Iron and Steel, and the Diffusion of Hydrogen Through the Metal," by C. A. Edwards. (5) "Examination of Iron from Konarak," by J. N. Friend and W. E. Thorneycroft. (6) "On the Nature of High-Speed Steel," by M. A. Grossman and E. C. Bain. (7) "Improvements in the Brinell Test on Hardened Steel, including a New Method for Producing Hard Steel Balls," by A. Hultgren. (8) "Present Position of the Theories of the Hardening of Steel," by W. Rosenhain. (9) "Effect of Free Surfaces on the Plastic Deformation of Certain Metals," by F. C. Thompson and W. E. W. Millington.

Sept. 8 to 11. INSTITUTE OF METALS. Annual Autumn Meeting, to be opened at the Institution of Mechanical Engineers, when W. M. Corse, S.B., will deliver the third annual Autumn Lecture. On September 9 the morning will be devoted to reading and discussion of papers, followed by luncheon at the Connaught Rooms, Kingsway, the afternoon to be spent at Wembley.

The following papers will be read:—"A Method for Measuring Internal Stress in Brass Tubes," by R. J. Anderson and E. G. Fahlman; "The Application of the Ideal Solubility Curve to the Interpretation of Equilibrium Diagrams in Metal Systems," by D. H. Andrews and Prof. J. Johnston; "Seventh Report of the Corrosion Research Committee of the Institute of Metals," by G. D. Bengough and R. May; "Comparative Results on Copper-Silicon-Aluminium and Other Aluminium Alloys as Obtained on Separately Cast Specimens and Specimens cut from a Crankcase Casting," by E. H. Dix and A. J. Lyon; "The Determination of Sodium in Aluminium," by D. M. Fairlie and G. B. Brook; "The Extrusion of Brass Rod by the Inverted Process," by R. Genders; "Investigation of the Effects of Impurities on Copper. Part II—The Effect of Iron on Copper," by D. Hanson and Grace W. Ford; "The Relationship Between Tensile Strength, Temperature and Cold-Work in Some Pure Metals and Single Solid Solutions," by D. H. Ingall; "On the Effect of Progressive Cold-Rolling on the Brinell Hardness of Copper," by H. Moore; "Experiments on the Working of Nickel for Coinage," by Sir T. K. Rose and J. H. Watson; "Some Experiments on the Effect of Casting Temperature and Heat-Treatment on the Physical Properties of a High-Tin Bronze," by F. W. Rowe; "Some Experiments on the Influence of Casting Temperature and Mass on the Physical Properties of Admiralty Gun-Metal," by F. W. Rowe; "Studies in the Aluminium-Zinc System," by T. Tanabe; "Metal Spraying and Sprayed Metal," by T. H. Turner and W. E. Ballard.

SOCIETY OF CHEMICAL INDUSTRY

CHEMICAL INDUSTRY DINNER

It has been arranged that the Autumn Dinner, already intimated to be held on November 14, will be a joint function under the auspices of the Society of Chemical Industry and the Chemical Industry Club. The Dinner will be held in the Edward VII Rooms of the Hotel Victoria, Northumberland Avenue, London, W.C. 2, and will be presided over by Mr. W. J. U. Woolcock, C.B.E., President of the Society.

It is hoped that a large number of members of each of the bodies mentioned will, in due course, procure tickets for themselves and their ladies. A circular letter with further particulars and a form of application for tickets will be issued early in September, but members are asked in the meantime to note the above date and place for the dinner.

BACK NUMBERS OF JOURNAL

The General Secretary will be glad to hear from Members or Subscribers who have copies of the *Journal* for January 5, 1923, or January 4, 1924, that they are willing to dispose of to the Society.

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

The price of Volume VIII (1923) to members of the Society is 7s. 6d., and to non-members 12s. 6d., post free in each case.

Fellows of the Chemical Society have the privilege of purchasing the volume at the price of 10s. post free.

A set of Volumes II to VIII inclusive can be purchased by a member of the Society at the price of £2 2s. 6d., and by a non-member at the price of £3 15s., post free in each case.

CHEMICAL SOCIETY'S ANNUAL REPORTS

The Council of the Chemical Society has decided to increase the price of future issues of the Annual Reports on the Progress of Chemistry, and the volume for 1924 (XXI) which will be issued next year will be sold to the public at 10s. 6d., plus postage. To members of the Society of Chemical Industry will be given the privilege of purchasing the volume at 9s., post free. Orders, accompanied by the appropriate remittance, should be sent to the Assistant Secretary, Chemical Society, Burlington House, London, W. 1, before the end of the present year.

ROTHAMSTED LIBRARY

By the courtesy of the Lawes Agricultural Trust, any member of the Society of Chemical Industry on presenting a card from the General Secretary shall be allowed access to this Library. The rules of the Library preclude journals and periodicals from being sent out, and these are therefore always accessible.

A catalogue of the journals and periodicals is in the Society's Offices, at Central House, and may be consulted there by members.

DEATH

Bird, William R. (elected 1902), of 217, Newport Road, Cardiff, Director. On August 13, 1924.

THE BRITISH CHEMICAL PLANT MANUFACTURERS' ASSOCIATION

The fourth annual meeting was held on July 30, and Mr. L. M. G. Fraser, M.I.Chem. E. (the retiring chairman), in moving the adoption of the report and accounts, reviewed the demand for increased and more efficient production, and showed the need for the work of the chemical engineer. Caution was advised against the tendency to teach too much or extend the training too long. In the works, a good understanding of the principles of physics and mathematics was required rather than high attainments in these branches of science, for, although the mechanical sciences were largely exact sciences, all the problems of the chemical engineer were hedged about by the incalculable—sudden alterations at critical temperatures, unknown surface tension—and in such cases experience was the deciding factor.

The improvements in the construction of chemical apparatus could be broadly classified as follows:—(1) Better products obtained; (2) Lower working costs; (3) Cheaper apparatus; (4) Safer operations.

Better apparatus was being obtained by the use of known metals or alloys which had been tested under varying conditions, both under laboratory and works conditions, and there were alloys which prevented contamination of the material being manufactured without troubles of purification in the later stages, and which also gave longer life to the plant. The action of heat under varying conditions was more intimately known, and overheating was more easily guarded against. The improvements in grinding machinery had enabled many hard materials to be satisfactorily ground to required fineness without undue proportion of dust or contamination and consequently with a better chemical reaction where required in the later stages of the process. The increased use of mechanical screening relieved the mill, increased the output and saved power and time. In past days, only ½-ton per hour was obtained from grinding plant with certain materials per horsepower, whereas to-day five or more times that amount could be turned out per hour with no more power absorbed, and less wear and tear on the plant. The formation of emulsions by high-speed mills had been made easier. The knowledge of filtration had increased the usefulness of the filter press. Continuous filters had proved their utility and the latest developments of the stream-line filter were being carefully followed.

In distillation, owing to the recognition of the importance of increased velocities, greater results per square foot of surface had been obtained, and more delicate materials could be handled with less risk. The action inside the still column was being more clearly grasped; the column could give cleaner cuts in the fractions, with greater purity, and columns could be designed to give continuously two or three fractions.

Mechanical crystallisers were again being brought forward, and it was claimed that they yielded better and purer crystals.

The problems of mixing dry and wet materials could yet be studied with advantage, and a great deal of useful power saved by studying the rapidity of the absorption of chemical reaction that is required to take place. Where the time factor entered, large mixers with slow motion and less relative power might be advantageous, and with rapid solution small mixers and quick motion was advisable. There were cases where a very large amount of power was saved when several dry ingredients had to be mixed, simply by studying the order in which the materials were put into the mixer.

Furnaces had received far more attention, and the importance of scientific furnace setting was now recognised, and whilst oil burners, gas firing, mechanical stokers, and mechanical draught all increased efficiency, they resulted in more severe furnace conditions, and contributed to frequent breakdowns unless careful thought was given both to the design and to the refractory materials and cements used.

Electricity was continually becoming more widely used in chemical industry in the electrolysis of alkali chlorides, water and organic compounds, and also as a means of separating either solid matter or vapour in the form of mist or fog. Much research work has been carried on to make improvements to the diaphragm and anodes: the improvements, though slow, were continuous. The electrolysis of salt had reached a very high state of commercial efficiency. Electrolysis of water appeared to have gone as far as possible. The electrolysis of inorganic compounds awaited development, but the plant could be properly designed. The highly complicated reactions that took place, however, did need investigation. Electro-reduction was more promising, and in Italy one firm used an ordinary cell for making mercury amalgam, used to reduce organic compounds.

The separation of ashes from coke and unburnt coal by means of electromagnetic separators was now being carried out commercially.

Lower working costs had been attained mainly through the more detailed study of the power factor in connexion with the movement of bulk material, or in the saving of heat by studying the thermal efficiency of fuel or interchange of heat from one material to another, and the greater freedom from breakdown of machinery and plant, causing dislocation of work. The automatic control of temperatures, automatic electric appliances for moving bulk material, automatic filling, weighing and packing, were other factors in the lowering of cost of production of chemicals.

Cheaper apparatus was now obtained, owing principally to the large amount of research work on rates of flow, whether in calories or liquids, and which had enabled the engineer the better to calculate the strains and stresses and outputs under which his machinery had to perform. In other words, he was able to reduce the incalculable quantity. Many other improvements in various types of machinery were the outcome of practice and experience, which, although not fundamental departures, were improvements in detail or alterations to main branches of the general principle.

The sum of all these improvements had made it possible to surmount many difficulties, and to lay plans with greater confidence.

The Report, which showed that the Association had a very useful year, was adopted and the following officers and committee for the ensuing year were elected :—Chairman, Mr. F. R. Blizzard (T. & C. Clark & Co., Ltd.); Vice-Chairman, Mr. J. Robinson (Mather & Platt, Ltd.); Treasurer, Mr. E. A. Alliott (Manlove, Alliott & Co., Ltd.); Committee, Mr. H. Bush (Huntingdon, Heberlein & Co., Ltd.); Mr. L. M. G. Fraser (W. J. Fraser & Co., Ltd.); Mr. J. A. Revell (Kestner Evaporator and Engineering Co., Ltd.): Dr. R. Seligman (Aluminium Plant and Vessel Co., Ltd.), Mr. E. C. Watkins (W. Neill & Son. Ltd.), Mr. J. W. Wright (Cannon Iron Foundries, Ltd.).

ANNOUNCEMENT OF CHEMICAL EXPOSITION DATE

Owing to some confusion which is believed to exist in a few quarters regarding the holding of the next chemical exposition, an announcement has been sent out by the International Exposition Company, under whose management the Exposition of Chemical Industries has been held since 1915. Numerous inquiries have been received by the management which lead it to believe that many interested parties are of the opinion that there will be a chemical exposition this year. This is not the case. There will be no chemical exposition in 1924, the next Exposition of Chemical Industries will be held September 28 to October 3, 1925, at the Grand Central Palace, New York.

"This Exposition will not be held in the United States prior to September, 1925," states the announcement of the management. "Numerous inquiries which we have received, lead us to believe that there is some uncertainty regarding the date of the next Exposition of Chemical Industries. As a result of a vote of exhibitors, taken last year, the decision was definitely reached at that time not to hold the Exposition in 1924, but to skip a year and hold the next one in 1925. Owing to the fact that the Chemical Exposition has been held without interruption since 1915, the many inquiries regarding the omission of the Exposition this year are only natural.

"At the same meeting in 1923, where time and place for the next Chemical Exposition were discussed and decided upon, the exhibitors decided by a large majority to hold all future Expositions in New York, and selected the Grand Central Palace for 1925. New York was decided upon as the logical place to hold the Expositions in the future, because it was believed to offer the best location and conditions to attract the greatest number of people interested in the Chemical Industries from all parts of the world. So that the matter may be definitely understood, the next Exposition of Chemical Industries will be held at the Grand Central Palace one year from this September, during the week of September 28 to October 3, 1925."

CORRESPONDENCE

VERSE RELATING TO SCIENCE

Sir,—The letter of Mr. C. G. Ruby in your issue of June 13 asking for verses of any kind relating to science awoke an idea long dormant in my mind. I have always been of opinions that poems on purely chemical subjects could be written, but, however much belaboured, my own muse steadily declines to work, and I never get beyond the first line.

Failing a poem, I have ventured to submit a sort of chemical drama, or rather it should be called a scenario. It is I believe quite up to the usual cinema standard, and it may attract the eye of some budding epic poet or film producer. To such I give it freely. If you, Mr. Editor, cannot grant the necessary space, my hopes of seeing a masterpiece rise from my humble foundations must perish.

"Ben Zeen, an old organic Radical, possesses a large collection of jewellery, including a magic ring and quite a number of chains. He is anxious to unite himself by double or even triple bonds to pretty Annie Line; the young lady, however, pooh-poohs the idea of any union, whether direct or co-ordinated, with the old fellow. She is in fact much attracted to Ben's nephew, Benzy Dean, who also is the possessor of a magic ring.

"Someone has stolen the nucleus from Ben's ring, and has substituted a very inferior ionic micelle in the para position. Suspicion falls on Benzy, who is forthwith thrown into prison and loaded with ions. Annie Line, activated by her pure B.P. love, engages the services of the two famous detectives Proton and Niton. Using the Perkin reaction, they find distinct traces of the emanation from the nucleus at the house of an old Auntie body, said to be equal to anything. Auntie is diazotised to the n'th degree, and, being thoroughly decomposed, confesses that the nucleus is concealed at the back of her house under a heap of hormones and other rubbish. It was given to her by an amphoteric girl, called Silly Kate, who had once been united to Ben Zeen by a side-chain, but had been reduced. In revenge she had dextrosely abstracted the precious nucleus." Here follow the usual dénouements and happy ending

This, I believe, is a pioneer attempt, and is no doubt capable of great improvement. For instance, a lot of comic business could be made out of the rivalry of Polly Morphous and Sally Cylic, two housemaids, for the hand of Nick L. Oxhide, a catalytic insurance agent. One can easily imagine how Sally and Polly hide behind X-ray screens, crawl under filter-beds, and make barricades of periodic tables and chairs of chemistry, while Nick climbs up fractionating columns and scrambles through diffraction gratings.

For him who would write chemical poetry there is no lack of heroines—they are everywhere. As it is I have to apologise to Miss Molly B. Denum and to quite a number of ladies named Ethyl, for not being able to find a place for them among by *dramatis personæ*.—I am, etc.,

E. G. Bryant

Box 11, Prieska S. Africa
August 5, 1924

PERSONAL AND OTHER ITEMS

The Southern Gas Association of America has completed the financial arrangements necessary to establish a chair of gas engineering at the Johns Hopkins University, Baltimore. The Association intends to make a continuous effort to influence the right sort of students to take the course so that the gas industry may be gradually rendered still more efficient.

A New Source of Hydrogen

During the recent Congress of Industrial Chemistry at Bordeaux, Prof Matignon described his work on the distillation of bituminous schists, and pointed out that these might become an important source of hydrogen. In fact, autun schists distilled in a closed vessel yielded per ton 63 cb. metres of gas containing carbon dioxide, 14 cb. m, carbon monoxide, 3 cb. m., hydrocarbons, 25 cb. m., hydrogen, 21 cb. m. The same schists distilled in Scotch retorts under certain conditions produced 670 cb. m. of gas of fairly low calorific power. To utilise the residual carbon formed during the distillation in the upper region of the vertical retort, steam is injected at the base, producing water gas which, mixed with the distillation gas yields, carbon dioxide. 139 cb m., ethylene, 5 cb. m.: oxygen, 24 cb. m.; carbon monoxide, 29 cb. m.: methane, 45 cb. m.; hydrogen, 171 cb. m.; nitrogen, 255 cb. m. After eliminating the carbon dioxide and nitrogen, the gas constitutes a useful source of hydrogen. In a gas-tight plant each ton of schist would yield 345 cb. m. of gas containing 173 cb. m. of hydrogen, and a works treating 100,000 tons of schist yearly would produce 17,000,000 cb. m. of hydrogen from which 8500 t. of ammonia could be produced. The unsaturated hydrocarbons could be recovered at the same time, and calculating from ethylene it would be possible to produce 5000 hectolitres of alcohol at the same time

GERMANY

Beryllium

In addition to the better-known light metals, which are now of great importance in Germany, beryllium has also been receiving some attention. Like aluminium, it is silver-white, hard, and fairly durable. In alloys it behaves similarly to silicon, but on account of its cost finds little application. Alloyed with copper to the extent of 5–10 per cent. it gives a product which does not oxidise in the air, can be hammered cold, and is easily worked. The colour is influenced by as little as 0·5 per cent. of beryllium; the alloy with 1·3 per cent. has a fine golden colour, whilst that containing 10 per cent. has only a faint yellow tinge. Alloys with aluminium, which may contain 1 to 99 per cent. beryllium are resistant to moisture; those containing a small amount of beryllium are stronger than similar alloys with magnesium and their specific gravity is considerably reduced; these alloys are thus very suitable for aircraft construction

Fuel Consumption of the Badische Anilin und Soda-Fabrik

In its factories at Ludwigshafen, Oppau, and Kerseberg, this company uses daily 2100 tons of hard coal, 1900 t. of coke, 600 t. of lignite briquettes, and 9000 t. of raw lignite. Pumps, compressors, etc., use 26,000 h.p., provided by 25 boiler houses containing 270 boilers with 1,260,000 sq. ft. of heating surface.

The Cracking of Heavy Oils

A new method for the cracking of heavy oils due to Dr. Blumner is described in *Brennstoffchemie*. In the present cracking processes light oils are produced, together with tar and coke, but in Blumner's process it is claimed that no coke is formed. The oil to be cracked is mixed with the residue from a previous run and sprayed into an autoclave at 450–500° C., which contains melted lead. The oil is kept in intimate contact with the lead, but is not allowed to touch the walls of the autoclave. The gases and oil are removed at the top and the tar and high-boiling point oils removed at the side. The remainder is passed through a fractionating column maintained at 210 220° C., the condensate in this column being the portion mixed with fresh oil as mentioned above. The benzine is condensed and the residual gases used to heat the autoclaves. About 70 per cent. of the crude oil is thus obtained as benzine.

FRANCE

Industrial Steaming Practice in France

During a recent lecture given by Monsieur Roszak before the Ecole de Perfectionnement Industriel, particular attention was paid to the three characteristics of a boiler plant, the size of the units, the working pressure, and the degree of super-heat. The increase in the size of the units beyond those actually carried out were not considered advantageous, as the actual advantages such as yield, economy of construction and gain of space were less important than was once thought, being far from compensating the increased risk of shutting down the plant. The probability of shutting down a unit owing to a leak in one of the tubes was proportionate to the number of tubes, and the fragility of the furnace refractories increased greatly with larger furnaces, thus again increasing the risk of breakdowns. The possibility of progress lay in the progressive increase of the pressure far beyond values now accepted. Recent researches had confirmed the clear trend towards the maximum of the curve of total heat of vaporisation as a function of the temperature. The same total heat could be furnished by one kg. of water either at the temperature of the ascending part of the curve, or at the temperature still higher on the descending side of the curve, thus admitting of a higher thermal yield. In addition the proportion of total heat furnished to the water was greater, thus making it possible to develop the relative influence of the recuperators and increasing the coefficient of utilisation of the heat produced by the fuel. To illustrate the nature of the changes that increased pressure brings about in the utilisation of boilers, it was of interest to consider the curious phenomena that are manifest when the critical point is approached. The expansion of the water became great and its density at the critical point was one-third of its normal density. The diminution of the latent heat in evaporation greatly reduced the size of the boiler

to the profit of the pre-heaters acting as recuperators. In addition the small difference of density between water and steam completely changed the conditions of evolution of bubbles and required the water to be circulated mechanically in the boiler. The increase in the density of the steam and the pressure also greatly facilitated the exchange of heat in the superheaters.

GENERAL

Italian Chemical Industry

Progress is being made in establishing the country as independent of foreign supplies of fixed nitrogen, while the colour and artificial silk industries have also advanced greatly. The chemical industry is capitalised to the extent of 422 million lire; annual production is valued at one milliard lire, one third of this being exported.

COMPANY NEWS

CHLORIDE ELECTRICAL STORAGE

The profit for the year to March 31, less provision for depreciation and taxation, was £115,542; available with £33,016 brought forward £44,557. The final dividend is 5 per cent. and bonus 10 per cent., making 20 per cent., tax free; £50,000 is placed to reserve, and £44,888 carried foward.

UNITED ALKALI CO., LTD.

An interim dividend of 5 per cent. is announced, compared with 4 per cent. at this time last year, the final dividend of 6 per cent. again making 10 per cent. for the year. In April, 1923, a capitalised bonus of 50 per cent. was distributed, raising the issued ordinary capital to £900,000.

UNITED TURKEY RED CO., LTD.

An interim dividend is announced of $2\frac{1}{2}$ per cent. actual, tax free. No dividend was distributed on the ordinary shares for 1921 and 1922, but $2\frac{1}{2}$ per cent., tax free. was paid for 1923, together with twelves months' arrears of dividend on the second preference shares.

AUTOMATIC AND ELECTRIC FURNACES, LTD.

In order to meet the increasing demand for large size Wild-Barfield Patent Electric Furnaces, with Internal Heaters, arrangements have been made whereby all such furnaces above 25 K.W. will in future be designed by Automatic and Electric Furnaces, Ltd., in conjunction with Electric Furnace Co., Ltd., of 17 Victoria Street, S.W. 1, and supplied by them. Arrangements have also been made with G. J. Hagan Co., of Pittsburg, U.S.A., who have constructed a large number of electric resistance furnaces up to 350 K.W. capacity, for the use of their drawings and information, so that the best British and American practice will be incorporated in the designs. The manufacture of Wild-Barfield Automatic Hardening Furnaces with magnetic detector, and internally heated type of Furnaces up to 25 K.W. will be continued by Automatic and Electric Furnaces, Ltd.

REVIEWS

Allen's Commercial Organic Analysis. Part I. By S. S. Sadtler, S.B., E. C. Lathrop, A.B., Ph.D., and C. Ainsworth Mitchell, M.A. Pp. viii.+796. London: J. and A. Churchill. 1924. Price 30s.

This new edition of Allen continues the practice begun in the last edition, and rendered more than ever necessary by the advance of science and the increasing bulk of specialised knowledge, of entrusting the revision of each section to an expert in its subject. If, as the result, there is some lack of uniformity in treatment, looking at the book as a whole, this is more than outweighed by the authoritative and "first hand" character of most of the information.

The subjects treated are practically the same as those in the corresponding volume of the fourth edition; and the increase in the bulk of the volume by 40 per cent. gives some indication of the amount of work which has been done during the fifteen years' interval between the editions, the results of which are here embodied.

It may be said at once that, as a whole, the book keeps up its high character, and that the changes, both of addition and of excision, seem to reflect faithfully the progress that has been made: the book remains a trustworthy guide. Additional matter is especially conspicuous in the sections on methyl alcohol and acetone, wines, chloroform and carbon tetrachloride, chemical methods for sugar determinations, pentoses, starch, mechanical tests for paper, vinegar, and tartaric acid. An excellent feature of the book is that in so many places typical analyses of the substances under discussion are given. This should be more frequent in analytical treatises.

It seems a pity that more revision was not effected in the first section. The application of physical methods to chemical work has been so greatly developed of late that it is disappointing to find in this section merely a reprint. The excision of the descriptions and figures of purely general and elementary apparatus like specific gravity bottles, separating funnels, and drying ovens, and the insertion of paragraphs on hydrogen ion determination, for example, would certainly be a change for the better. Parenthetically, the writer can never understand why the Sprengel tube is so constantly figured in English chemical literature, whilst the enormous improvement on it devised by our own Perkin (Chem. Soc. Trans., 1884, **45**, 443; 1896, **69**, 1043) is scarcely ever mentioned.

Allen is nowadays a book both for American and for English chemists, and is edited more or less for the requirements of both. In some respects this is an advantage to the English reader many excellent analytical methods of the A.O.A.C., for example, are made available to English workers who otherwise might not have come across them—but in other respects it is far from being so. Thus, new tables of specific gravity of alcohol and water mixtures have been inserted, from which the percentage of proof spirit by volume corresponding with any specific gravity has disappeared; surely an alteration which, in view of the legal position of proof

spirit in this country, should not have been made. And when, in an edition of a book published in London for British workers, we find an official American method for determining moisture in wood pulp fully described, whilst the official British method, entirely different, is ignored, can we be blamed for feeling that things are not altogether as they should be?

Naturally, there are here and there American expressions—"an aliquot," "a high-grade absolute," "are apt to be *quite* coloured," the use of "per cent." for "percentage," and of the misleading and untruthful "water-white" for "colourless." These are few in number, and for the most part not very objectionable; but the writer hopes that all right-minded persons, American as well as British, will agree that such sentences as "Hydrometers are graduated to read in direct or according to an arbitrary scale," or "The point to which the spindle sank in a 15 per cent. salt solution was marked 15 and in pure water as O and extending the scale," are inexcusable. There are very few misprints. Curiously, the two which the writer noticed, *is* for *in*, on page 46, and *corbonyl* chloride on page 84, are both brought over from the last edition.

Its virtues far outweighing its faults, the new Allen will worthily displace the old; it will doubtless enter many laboratories on the reputation of its ancestors, but it will remain, as an honoured inmate, on its own. J. T. DUNN

DIE FERMENTE UND IHRE WIRKUNGEN. By PROF. CARL OPPENHEIMER. With an appendix on "PHYSIKALISCHE CHEMIE UND KINETIK," by DR. RICHARD KUHN. Fifth edition, revised. Part I. pp. vii+160. Leipzig: G. Thieme, 1924. Price $1·90.

The original edition of this work was published in 1900 as a book of 350 pages, whilst the present edition will be completed in the course of about a year in 10—12 parts each of some 10 sheets (160 pages). The entire work will comprise two volumes, but the publishers announce that single parts cannot be supplied.

The subject of fermentation is treated in its broadest sense, all changes which occur in the living organism being dealt with under that head. From a synopsis published with this part it would appear that the text will be entirely academic, the application of fermentation to the arts and manufactures being excluded. Some idea is afforded of the enormous additions to our knowledge of fermentation phenomena in a quarter of a century by the extension of this work during that period from a small handbook to a voluminous treatise. We do not propose to comment on Prof. Oppenheimer's book until it has been completed further than to say that, judging from the part before us it will give by far the most exhaustive account of the subject of any work yet published. We hope to prepare a review when the entire work is before us. Meanwhile we are quite safe in recommending those of our readers who are interested in fermentation to add the book to their libraries.

ARTHUR R. LING

SPECTROSCOPY. By E. C. C. BALY, C.B.E., M.Sc., F.R.S. Pp. xi+298. Third Edition. Vol. I. London: Longmans, Green and Co. 1924. Price 14s.

The previous edition of this book appeared in 1912. Since that time probably no branch of physics has made such tremendous advances as has spectroscopy. To-day it occupies one of the foremost places—if not the foremost place—in those departments of scientific work which have for their object the determination of the fundamental laws of the structure of matter. This has come about, of course, largely through the Bohr theory of spectral emission and its developments, but it is due in no small measure also to the extension of experimental investigation into the previously unexplored regions of the far ultra-violet spectrum. On both the practical and the theoretical side spectroscopy has taken on a new aspect, and it is now so complex and specialised that the need of a reliable comprehensive text-book has become urgent.

The twofold aspect of the subject is doubtless one of the reasons which led the author very wisely to produce the new edition of this important work in two volumes, of which only the first has now appeared. It is, however, clearly not the only reason. The subject-matter is that of the first chapters of the previous edition (with the exception of Chapter IX. on "Interference Methods in Spectroscopy"), and the second volume will therefore contain a very large amount of matter also dealing with the experimental side of spectroscopy. This is as it should be, although those who have become bewildered by the intricacy of the theoretical developments of the last few years might pine for a smaller disproportion between theory and practice. It must be remembered, however, that the book is a text-book, and as such, must confine itself to results which are more or less firmly established. It is inevitable that, with such limitations, experiment must overbalance theory.

The first volume is, in the main, a reprint of the corresponding portions of the edition of 1912, although considerable additions and modifications of detail have been made to bring the work up-to-date. These are concerned mainly with new methods of investigation in the infra-red and ultra-violet regions, improved methods of mounting grating, and tables of standard international wave-lengths and connexions from wave-lengths in air to those in vacuum. Some misprints in the previous edition have been corrected, although on page 30 a property of the grating itself is still attributed to a particular method of mounting the grating, and on page 169 (fifth line from bottom), although some of the symbols have been changed, an error is retained which now consists in the printing of *m* instead of *p*. The only plate in the book—representing the spectra of copper and iron—is scarcely representative of the best results obtainable with even a moderate instrument. These, however, are minor points. The book as a whole is admirably planned and executed and will be found invaluable to anyone who has occasion to use the spectroscope for any purpose whatever.

H. DINGLE

Kolloidchemie und Biologie. By H. Freundlich. Pp. 47. Theodor Steinkopff. Dresden und Leipzig. 1924. Price $0·50.

This little book originated in a recent lecture, by the author, on the relation between colloidal chemistry and biology; it is at the same time a third edition of the author's "Kapillarchemie und Physcologie," of which two editions appeared more than ten years ago. The great development of colloidal chemistry, to which the author has largely contributed, falls almost wholly in the present century and although the subject cannot compare in fundamental importance with contemporary developments in the theories of atomic structure or of relativity, it yet has an interest of its own, for colloidal chemistry is and will remain a basis for an understanding of vital phenomena.

In this little book Prof. Freundlich deals with some elementary and fundamental notions, perhaps not always so fully as to make them really intelligible to those unacquainted with the subject. His object is apparently rather to remind his biological readers of the achievements of colloidal chemistry and then to discuss its recent applications, such as, for instance, Warburg's conclusion that carbon assimilation, respiration and fermentation are all processes which, like adsorption, take place on a surface. A trace of iron on the surface of charcoal catalyses the oxidation of amino-acids. Cyanides stop this oxidation, just as they "poison" ferments. The applications of colloidal chemistry to the agglutination of bacteria, to phosphorescent organisms, and to many other biological phenomena are dealt with

In a book of this size we cannot, of course, expect the detailed or comprehensive treatment of text-books like "Bechold's Die Kolloide in Biologie und Medizin," or Höber's "Physikalische Chemie der Zelle und Gewlbe," but what Prof Freundlich has selected is all the more up to date and all the more suggestive. We are a little surprised at the inclusion of a discussion of electrokinetic and Nernst potentials in a book of this scope.

G. Barger

Theoretical Metallurgy. By R. Scott Dean. Pp. vii+246. London: Chapman and Hall, Ltd., 1924. Price 15s.

Schenck's work on "The Physical Chemistry of Metals," which has been found valuable by many teachers and students of metallurgy on account of its novel and interesting discussion of technical problems in a scientific manner, was translated into English by Mr. R. S. Dean a few years ago. The subject had then advanced considerably, and the English translation lagged behind the knowledge of the day. The translator has now prepared a work on the same general plan and incorporating much of the earlier book, but with many additions, so that it is no longer a mere translation. Modern scientific metallurgy calls for some acquaintance with such departments of pure science as the structure of crystals as revealed by X-rays, and even with the modern theory of the constitution of the atom. These subjects are therefore dealt with, together with recent work on the growth and recrystallisation in metals, and the nature of surface phenomena. Some further notes on technical processes, such as wire drawing and extrusion, have been introduced, and the chapters on equilibria in smeltering processes have been considerably expanded. These chapters are perhaps the most interesting to the metallurgical student, who has otherwise to resort to German works for information on these subjects. The sections on metallic alloys are naturally only brief abstracts of what is to be found in text-books on metallography, and are perhaps too scanty to furnish more than suggestions. The principal defect of the book is, indeed, its scrappiness. Interesting subjects are dealt with in the course of a page or two with references to a few, but only a few, of the important papers on each subject. The effect on a keen student will be stimulating, since he will discover from an examination of the book that many familiar facts in metallurgy may be better understood by taking into account the results of modern physics and physical chemistry. The other defect is more serious. Inaccuracies are unfortunately very common. The author has become confused in regard to the allotropic modifications of iron, and the reader would fail to obtain an indication of the now well-established facts of allotropy. So on page 30 the account of explosive antimony overlooks the fact that this substance is not an allotropic modification, but contains chlorine as one of its constituents. The author is unlucky in dealing with steels. The account of the alloys of iron and nickel overlooks the important work of Benedicks and Hanson, and might well have included a discussion of the relation to meteorites. The succeeding paragraph on permanent magnets completely fails to represent present practice, and the account of the hardening of steel on page 152 is inaccurate. It is also incorrect to say that the iron-chromium alloys used for resistance to corrosion contain more than 15 per cent. of chromium. It must be added that misprints are very frequent, proper names are often spelt wrongly, and figures in the references are incorrect. On page 68 both the algebraic formulæ, of considerable interest to the reader, are printed wrongly, and the errors in some instances are such as to make it very difficult to discover the true reference or the true formula. In spite of these faults the book is an interesting one, and it is a matter for regret that so excellent an idea has not been carried out with more care.

C. H. Desch

The Quebec Government is spending an additional $500,000 on the St. Maurice River. This will make a total of $3,000,000 in all, expended for storage dams on the river. The Government is expending $950,000 at Lake Kenogami, which makes total expenditure for daming this lake of $2,750,000. A number of smaller sized dams are being placed in rivers throughout the province. These works are all revenue producers, as the fees for the supply of water return a substantial amount.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech.	£23 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	£45 per ton.
Powder	£47 per ton.
Acid Hydrochloric	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers' works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Copper Sulphate	£25 per ton.
Methylated Spirit 64 o.p.—	
Industrial	3s. 1d.—3s. 5d. per gallon, according to quantity.
Mineralised	4s. 2d.—4s. 6d
Nickel Sulphate	£38 per ton d/d. Normal business.
Nickel Ammon. Sulphate	
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	5¾d. per lb.
Potass. Chlorate	3d.—4d. per lb
Salammoniac	£32 per ton d/d.
Salt Cake	£3 10s. per ton d/d.
Soda Caustic, solid	Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton, carr. paid.
Sod. Bichromate	4½d. per lb.
Sod. Bisulphite Powder 60/62%	£18—£19 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrite refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Sulphide conc. 60/65	About £14 10s. per ton d/d.
Sod. Sulphide cryst.	£9 per ton d/d.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	5¾d.—1s. 4d. per lb., according to quality.
Crimson	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 11d. per lb.
Barytes	£3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide	3s. 9d.—4s. per lb., according to quantity.
Carbon Bisulphide	£30—£33 per ton according to quantity. Again dearer.
Carbon Black	7d.—7½d. per lb. ex wharf. Dearer.
Carbon Tetrachloride	£60—£65 per ton according to quantity, drums extra. Again dearer.
Chromium Oxide green	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	5d.—9½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	£48 per ton, barrels free. Advanced.
Lead **Hyposulphite**	7½d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£16 5s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Sulphur Precip. B.P.	£56—£57 per ton, according to quantity.
Sulphur Chloride	4d. per lb., carboys extra. Dearer.
Thiocarbanilide	2s. 6d. per lb.
Vermilion, pale or deep	5s. 1d. per lb. dearer.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

"Summer conditions" prevail in this as in most industries.

Acetate of Lime—	
Brown	£12—£12 5s. per ton d/d. Market easier.
Grey	£17—£18 per ton. Market easier.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 10s.—£9 per ton, according to grade and locality. Demand fairly good.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 7d. per gall. Unrefined.
Wood Naphtha—	
Miscible	4s. 10d.—5s. per gall. 60% O.P. Market dull.
Solvent	5s. 6d. per gall. 40% O.P. Fairly good demand.
Wood Tar	£4 per ton. Cheaper.
Brown Sugar of Lead	£44 per ton. Cheaper.

TAR PRODUCTS

Acid Carbolic—	
Crystals	6¼d. per lb. Quiet.
Crude 60's	1s. 9d.—1s. 11d. per gall., according to district. Still quiet.
Acid Cresylic, 97/99	2s.—2s. 1d. per gall. Demand fair.
Pale 95%	1s. 10d.—2s. per gall. Fair demand.
Dark	1s. 9d.—2s. per gall. Quiet.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	7½d.—9d. per gall. Quiet.
Unstrained	7d.—7½d. per gall.
Benzole—	
Crude 65's	10½d.—1s. per gall. ex works in tank wagons.

Benzole—	
Standard Motor	.. 1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure	.. 1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.
Toluole—90% ..	.. 1s. 5d.—1s. 5½d. per gall. Small demand.
Pure ..	.. 1s. 8d.—2s. per gall. Small demand.
Xylol coml. ..	.. 2s. 3d. per gall.
Pure ..	.. 3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	.. 8½d. per gall. Not much business.
Middle Oil ..	.. 5d.—6½d. per gall., according to quality and district. Small export inquiry. Market quiet but fairly steady.
Heavy Oil ..	..
Standard Specification	
Naphtha—	
Solvent 90/160	.. 11½d.—1s. 3d. per gall., according to district. Fair demand.
Solvent 90/190	.. 11½d.—1s. 1½d. per gall. Fair demand.

Naphthalene Crude—
Market dull. Not much export inquiry. Cheaper in Yorkshire than Lancashire.
Drained Creosote Salts £4—£6. Quiet.
Whizzed or hot pressed £7—£9 per ton.

Naphthalene—	
Crystals and Flaked	.. £13—£16 per ton in Yorkshire and London respectively.
Pitch, medium soft	.. 55s.—60s. per ton f.a.s. for next season. Frequent inquiries.
Pyridine—90/160	.. 19s. per gall. Again dearer. Market firm.
Heavy	.. 12s.—12s. 6d. Little business.

INTERMEDIATES AND DYES

Business in dyestuffs has not been good lately, but an improvement is expected after the holidays. Prices remain firm.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	.. 1s. 7d. per lb.
Acid H.	.. 4s. per lb. 100% basis d/d.
Acid Naphthionic	.. 2s. 4d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech.	.. 1s. 1d. per lb. Improved demand.
Acid Sulphanilic	.. 9½d. per lb. 100% basis d/d.
AluminiumChloride,anhyd.	1s. per lb. d/d.
Aniline Oil ..	.. 7¾d.—8½d. per lb. naked at works.
Aniline Salts	.. 7¾d.—9d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base ..	.. 4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95%	.. 1s. 1d. per lb.
p-Chlorphenol ..	.. 4s. 3d. per lb. d/d.
p-Chloraniline ..	.. 3s. per lb. 100% basis.
o-Cresol 19/31° C.	.. 4½d. per lb. Demand steady.
m-Cresol 98/100%	.. 2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	.. 2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline ..	.. 2s. 3d.—2s. 11d. per lb.
Dichloraniline S. Acid	.. 2s. 6d. per lb. 100% basis.
p-Dichlorbenzol ..	.. £85 per ton.
Diethylaniline ..	.. 4s. 6d. per lb. d/d., packages extra, returnable.
Dimethylaniline ..	.. 2s. 3d. per lb. d/d. Drums extra.
Dinitrobenzene ..	.. 9d. per lb. naked at works.
Dinitrochlorbenzol	.. £84 10s. per ton d/d.
Dinitrotoluene—48/50° C.	8d.—9d. per lb. naked at works.
66/68° C.	1s. 2d. per lb. naked at works.
Diphenylamine ..	.. 2s. 10d. per lb. d/d.
Monochlorbenzol	.. £63 per ton.
β Naphthol ..	.. 1s. 1d. per lb. d/d.
α-Naphthylamine	.. 1s. 4d. per lb. d/d.
β-Naphthylamine	.. 4s. per lb. d/d.
m-Nitraniline ..	.. 4s. 9d. per lb. d/d.
p-Nitraniline ..	.. 2s. 3½d. per lb. d/d.
Nitrobenzene ..	.. 5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol	.. 2s. per lb. 100% basis d/d.
Nitronaphthalene	.. 10½d. per lb. d/d.
p-Nitrophenol ..	.. 1s. 9d. per lb. 100% basis d/d.
p-Nitro-o-amido-phenol	4s. 6d. per lb. 100% basis
m-Phenylene Diamine	.. 4s. per lb. d/d.
p-Phenylene Diamine	.. 10s. 3d. per lb. 100% basis d/d.
R. Salt	.. 2s. 6d. per lb. 100% basis d/d.
Sodium Naphthionate	.. 2s. 3d. per lb. 100% basis d/d.
o-Toluidine ..	.. 8½d. per lb.
p-Toluidine ..	.. 3s. 3d. per lb. naked at works.
m-Toluylene Diamine	.. 4s. 3d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P	.. £45 per ton.
Acid, Acetyl Salicylic	.. 3s. 2d.—3s. 4d. per lb., according to quantity. Good demand. Price firm.
Acid, Benzoic B.P.	.. 3s. per lb.
Acid Boric B.P. ..	.. Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric ..	.. 19s.—21s. per lb.
Acid, Citric ..	.. 1s. 4½d.—1s. 5d. per lb., less 5% for ton lots. Market very weak.
Acid, Gallic ..	.. 3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst	.. 6s. 9d. lb. Resublimed quality 8s. per lb. Market firm, increasing demand.
Acid, Salicylic ..	.. 1s. 6d.—1s. 9d. per lb. Market unsettled and difficult.
Acid, Tannic B.P.	.. 3s. per lb. Market quiet.
Acid, Tartaric ..	.. 1s. 1½d. per lb. less 5%.
Amidol	.. 9s. per lb. d/d.
Acetanilide ..	.. 2s. 1d. 2s. 3d. per lb. for quantity. Demand slow.
Amidopyrin ..	.. 13s. 3d. per lb. Neglected. Stocks low.
Ammon. Benzoate	.. 3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	.. 12s. 6d. per oz. for English make.
Barbitone	.. 15s.—15s. 6d. per lb. Quiet market.
Benzonaphthol ..	.. 5s. 3d. per lb. Small inquiry.
Bismuth Salts ..	.. Prices reduced by about 1s. 3d.—2s. 3d. per lb. on account of the fall in the price of the metal.
Bismuth Carbonate	.. 10s. 6d.—12s. 6d. per lb.
„ Citrate ..	.. 10s. 3d.—12s. 3d. „
„ Salicylate	.. 9s.—11s. „
„ Subnitrate	.. 8s. 8d.—10s. 8d. „
Borax B.P. ..	.. Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides	.. Unsettled. Spot supplies short. Raw materials dearer. Market very firm and advancing.
Ammonium ..	.. 1s. 3d.—1s. 5d. per lb.
Potassium ..	.. 1s. 1d.—1s. 3d. per lb.
Sodium ..	.. 1s. 2d.—1s. 4d. per lb.
Calcium Lactate ..	.. Market fairly firm and higher prices talked of. Good English make can be had from 1s. 6d. upwards.
Chloral Hydrate ..	.. 4s.—4s. 3d. per lb. Very firm and scarce.
Chloroform ..	.. 2s. per lb. for cwt. lots. Very steady.
Creosote Carbonate	.. 6s. 6d. per lb. Little demand.
Formaldehyde ..	.. £52 per ton, ex works. English make in casks.

Glycerophosphates—	Fair business passing
Calcium, soluble and citrate free ..	.. 7s. per lb.
Iron	.. 8s. 9d. per lb.
Magnesium ..	.. 9s. per lb.
Potassium, 50%	.. 3s. 6d. per lb.
Sodium, 50% ..	.. 2s. 6d. ,,
Guaiacol Carbonate	.. 10s. 6d.—11s. 3d. per lb.
Hexamine ..	.. 3s. 6d. per lb. for English make Market steady.
Homatropine Hydrobr'ide	30s. per oz.
Hydrastine hydrochlor ..	English make offered, 120s. per oz.
Hypophosphites—	
Calcium ..	.. 3s. 6d. per lb., for 28-lb. lots.
Potassium ..	.. 4s. 1d. per lb.
Sodium ..	.. 4s. ,,
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 5d. per lb., according to quantity.
Magnesium Carbonate—	
Light Commercial	.. £36 per ton net.
Magnesium Oxide—	
Light Commercial	.. £75 per ton, less 2½%.
Heavy Commercial	.. £25 per ton, less 2½%. Price reduced.
Heavy Pure ..	.. 2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	.. 62s. 6d. per lb. Market rising rapidly.
Synthetic ..	.. 26s.—35s. per lb., according to quantity. English make. Strong demand.
Mercurials ..	.. Market flat.
Red oxide ..	.. 5s. 3d.—5s 4d. per lb.
Corrosive sublimate	.. 3s. 6d.—3s. 7d. ,,
White precip. ..	.. 4s. 7d.—4s. 8d. ,,
Calomel ..	.. 3s. 11d.—4s. ,,
Methyl Salicylate	.. 1s. 10d.—2s. 1d. per lb. Keen competition.
Methyl Sulphonal	.. 26s. per lb.
Metol	.. 11s. per lb. British make.
Paraformaldehyde	.. 2s. 10½d.—3s. per lb. Not very active.
Paraldehyde ..	.. 1s. 5d.—1s. 6d. per lb. in free bottles and cases.
Phenacetin ..	.. 6s. per lb. Price and demand steady.
Phenazone ..	.. 7s. 6d. per lb. A shade firmer. Forward prices higher.
Phenolphthalein ..	.. 6s. 6d. per lb. Ample supplies.
Potass. Bitartrate—	
99/100% (Cream of Tartar) ..	.. 88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate ..	.. 1s. 10d.—2s. 2d. per lb.
Potass. Iodide ..	.. 16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues heavy.
Potass. Metabisulphite	.. 7½d. per lb., 1-cwt. kegs included.
Potass. Permanganate	.. 7½d. per lb.
Quinine Sulphate	.. 2s. 3d. per oz., in 100 oz. tins. Very heavy demand.
Resorcin	.. 5s. 2d. per lb.
Saccharin.. ..	.. 63s. per lb., in 50-lb. lots.
Salol	.. 3s. 6d. per lb.
Silver proteinate..	.. 9s. 6d. per lb.
Sod. Benzoate, B.P.	.. 2s. 6d. per lb. Ample supplies. B.P. quality available.
Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity.
Sod. Hyposulphite—	
Photographic ..	.. £13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	.. 16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	.. 75s.—82s. 6d. per cwt., accordin to quantity. Steady marke good demand.
Sod. Salicylate ..	.. Market more active. Powde 2s. 3d.—2s. 5d. per lb. Cryst at 2s. 5d.—2s. 7d. per lb. Flak 2s. 9d. per lb.
Sod. Sulphide—	
Pure recryst. ..	.. 10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Sulphonal.. ..	.. 15s. 6d. per lb. Easier.
Thymol	.. 19s. 6d. per lb. nominal. Very scarce indeed. Still rising.

PERFUMERY CHEMICALS

Acetophenone ..	.. 12s. 6d. per lb.
Aubepine	.. 15s. 3d. ,,
Amyl Acetate ..	.. 2s. 9d. per lb.
Amyl Butyrate ..	.. 6s. 9d. ,,
Amyl Salicylate ..	.. 3s. ,,
Anethol (M.P. 21/22° C.)	4s. 6d. ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 10½d. ,,
Benzyl Alcohol free from Chlorine ..	.. 2s. 10½d. ,,
Benzaldehyde free from Chlorine ..	.. 3s. 6d. ,,
Benzyl Benzoate	.. 3s. 6d. ,,
Cinnamic Aldehyde Natural.. ..	.. 16s. ,,
Coumarin ..	.. 19s. 6d. ,,
Citronellol ..	.. 17s. ,,
Citral	.. 9s. ,,
Ethyl Cinnamate	.. 13s. 6d. ,,
Ethyl Phthalate ..	.. 3s. 3d. ,,
Eugenol	.. 10s. 6d. ,,
Geraniol (Palmarosa)	.. 35s. ,,
Geraniol	.. 11s.—18s. 6d. per lb.
Heliotropine ..	.. 7s. 9d. ,,
Iso Eugenol ..	.. 15s. 9d. ,,
Linalol ex Bois de Rose..	26s. ,,
Linalyl Acetate ..	.. 26s. ,,
Methyl Anthranilate	.. 9s. 6d. ,,
Methyl Benzoate	.. 6s. ,,
Musk Ambrette ..	.. 45s. ,,
Musk Xylol ..	.. 14s. ,,
Nerolin	.. 4s. 9d. ,,
Phenyl Ethyl Acetate	.. 15s. ,,
Phenyl Ethyl Alcohol	.. 16s. ,,
Rhodinol	.. 57s. 6d. ,,
Safrol	.. 1s. 10d. ,,
Terpineol	.. 2s. 4d. ,,
Vanillin	.. 26s. per lb.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	.. 15s. 6d. per lb.
Anise Oil	.. 2s. 6d. per lb.
Bergamot Oil ..	.. 17s. 6d. per lb.
Bourbon Geranium Oil	.. 36s. 6d. ,,
Camphor Oil ..	.. 75s. per cwt.
Cananga Oil Java	.. 10s. 6d. per lb.
Cinnamon Oil, Leaf	.. 6½d. per oz.
Cassia Oil, 80/85%	.. 9s. 6d. per lb. Advanced.
Citronella Oil—	
Java 85/90% ..	.. 5s. 8d. per lb.
Ceylon ..	.. 3s. 7d. per lb.

Clove Oil	..	8s. per lb. Firmer.
Eucalyptus Oil 70/75%		2s. 4½d. per lb.
Lavender Oil—		
French 38/40% Esters		30s. per lb. Very firm. Higher price expected owing to bad crops.
Lemon Oil	..	3s. per lb.
Lemongrass Oil	..	3d. per oz.
Orange Oil, Sweet	..	13s. per lb.
Otto of Rose Oil—		
Bulgarian	..	37s. 6d. per oz. Production below average.
Anatolian	..	18s. per oz.
Palma Rosa Oil	..	18s. per lb.
Peppermint Oil—		
Wayne County	..	21s. 6d. per lb.
Japanese	..	17s. 3d. per lb. nominal. Market rising rapidly.
Petitgrain Oil	..	9s. 3d. per lb.
Sandal Wood Oil—		
Mysore	..	26s. 6d. per lb.
Australian	..	21s. per lb.

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition not later than October 20th, they are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on September 4th.

I.—Applications

Fraser, Rissik, Fraser & Co., Ltd. Colloidal mills etc. 19481. Aug. 16.

Hogan and Marshall. Apparatus for accumulating and discharging latent heat. 19,206. Aug. 13.

Joseph. Filters for air etc. 19,417. Aug. 15.

Lowe, Manchester Furnaces, Ltd. Muffle furnaces. 19,238. Aug. 13.

Synthetic Ammonia and Nitrates, Ltd. Catalyst. 19,445. Aug. 16. (U.S., 16.8.23.)

Te Aroha Dairy Co., Ltd. Deodorizing, cooling, and dehydrating fluid substances. 19,061. Aug. 11. (New Zealand, 14.8.23.)

I.—Complete Specifications Accepted

6599 (1923). Soderlund, Boger, Testrup, and Techno-Chemical Laboratories, Ltd. Separating solids from liquids. (220,015.)

19,656 (1923). Keene. Filtering-apparatus. (220,157).

21,584 (1923). Coward. Crushers and pulverizers. (220,176.)

27,039 (1923). Haddan (American Blower Co.). Method and apparatus for treating vapours. (220,201.)

1677 (1924). Rousseau. Ore pulverizers. (220,229.)

7082 (1924). Field. Method and apparatus for recovering solids from liquids by heat interchange. (220,253.)

II.—Applications

Denham and Jones. Producer-gas generators. 19,283. Aug. 14.

Escorihuela. Combustible product. 19,201. Aug. 13. (Spain, 13.8.23.)

Kohlenscheidungs Ges. Distillation of bituminous substances. 19,145. Aug. 12. (Ger., 28.11.23.)

Miniken. Apparatus for dewatering coal slimes. 19,108. Aug. 12.

Pintsch Akt.-Ges., J. Porous charges for containers for storage of acetylene etc. dissolved in liquids. 19,408. Aug. 15. (Ger., 16.8.23.)

Rosencrants and Vickers International Combustion Engineering, Ltd. Drying coal, etc. 19,023. Aug. 11.

Sankey. Manufacture of activated carbon. 19,128. Aug. 12.

Sauer. Manufacture of active carbons. 19,179. Aug. 13.

Synthetic Ammonia and Nitrates, Ltd. Gas purification. 19,447. Aug. 16. (U.S., 16.8.23.)

Ward. Apparatus for washing and separating coke etc. from clinker. 19,006. Aug. 11.

Winser. Retorts for distillation of oils etc. 19,214. Aug. 13.

II.—Complete Specifications Accepted

6165 (1923). Becker. Coking retort oven batteries with regenerators. (209,380.)

11,797 (1923). Firth, Blakeley, Sons and Co., Ltd., and Wright. Washers or purifiers for use in the manufacture of gas. (220,039.)

11,901 (1923). British Thomson-Houston Co., Ltd. (General Electric Co.). Electric incandescent lamps and filaments therefor. (220,045.)

15,948 (1923). McAlpine. *See* XXIII.

19,587 (1923). General Electric Co., Ltd. Manufacture of electrodes for tungsten arc lamps. (209,028.)

10,794 (1924). Farbwerke vorm. Meister, Lucius and Bruning. *See* XX.

IV.—Applications

Colloidal Colour Co., Ltd., Goedecke. Production of colour lakes. 19,496. Aug. 16.

Harris, Jones, Morton, Morton, Sundour Fabrics, Ltd., Wylam. Dyes and dyeing. 19,066. Aug. 11.

IV.—Complete Specifications Accepted

19,495 (1923). Farbenfabriken vorm. F. Bayer and Co. Production of dye-stuffs of the anthraquinone series. (201,575.)

30,390 (1923). Johnson (Badische Anilin and Soda Fabrik). Manufacture and production of green vat dye-stuffs. (220,212.)

30,721 (1923). Johnson (Badische Anilin and Soda Fabrik). Manufacture and production of vat dye-stuffs of the anthraquinone series. (220,216.)

31,989 (1923). Compagnie Nationale de Matieres Colorantes et de Produits Chimiques. Manufacture of a dye-stuff from naphthidine. (208,720.)

V.—Applications

British Celanese, Ltd., Ellis and Goldthorpe. Treatment of acetyl cellulose etc. 19,292. Aug. 14.

Kempter. Process of making viscose. 19,443. Aug. 16. (Ger., 15.5.24.)

Zdanowich. Manufacture of cellulose derivatives. 19,405. Aug. 15.

V.—Complete Specifications Accepted

17,883 (1923). Souchon. Method of and apparatus for bleaching cellulose pulp for the manufacture of paper. (220,137.)

18,226 (1923). Thomassen. Process for freeing paper pulp from impurities. (220,139.)

VI.—Applications

Harris, Jones, Morton, Morton, Sundour Fabrics, Ltd., Wylam. 19,066. *See* IV.

Mohr. Bleaching of textiles. 19,385. Aug. 15.

VII.—Applications

Casale. Catalytic synthesis of ammonia. 19,063. Aug. 11. (Italy, 29.3.24.)

Farbenfabriken vorm. F. Bayer and Co. Manufacture of highly-active silica gels. 19,416. Aug. 15. (Ger., 3.9.23.)

Liebreich. Production of solutions containing oxides of chromium etc. 19,226. Aug. 13.

Scott. 19,208. *See* IX.

VII.—Complete Specification Accepted

5699 (1923). Amber Size and Chemical Co., Ltd. (Muth). Manufacture of aluminium hydroxide. (220,011.)

VIII.—Applications

Bell. Production of refractory bodies for electrical purposes. 19,257. Aug. 13.

Colloidal Colour Co., Ltd., Goedecke. 19,496. *See* IV.

IX—Applications

Burney. Manufacture of artificial wood and of building elements therefrom. 19,332. Aug. 14.

JOURNAL of THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council of Pure and Applied Chemistry

which consists of Representatives from

The Chemical Society, the Society of Chemical Industry, the Association of British Chemical Manufacturers, the Institute of Chemistry, the Society of Public Analysts, the Faraday Society, the Institute of Brewing, the Society of Dyers and Colourists, the Society of Glass Technology, the Iron and Steel Institute, the Ceramic Society, the Institution of Gas Engineers, the Society of Leather Trade Chemists, the Royal Photographic Society, the Mineralogical Society, the Biochemical Society, the Institute of Metals, and the Royal Agricultural Society.

43 NEW SERIES | LONDON, JULY 4, 1924 | No. 27

EDITORIAL

THE first World Power Conference was opened in the conference halls of the British Empire Exhibition on Monday last by the Prince of Wales, and the serious business on the programme began on Tuesday. Representatives of no less than thirty different countries, including the British Dominions, will be busy for nearly a fortnight, discussing problems that are of vital importance. It is fitting that the Conference should be international rather than national, for its purpose is to discuss the various ways in which power can be utilised and how the sources of power can be adjusted both nationally and internationally. The programme is enormous and covers every aspect of the subject, over 300 papers having been prepared for the Conference. The discussion first centres on the potential resources of hydroelectric power, oil and minerals in each country, and the generation and utilisation of power; it then branches out to consider the necessary research in its widest sense, and there will be conferences on the development of scientific agriculture, on technical education and its improvement, on the economic and financial aspects, both national and international, of industry, and many other subjects. As the Prince of Wales said, in his opening speech, "the study of power is still in a comparatively elementary stage, and no effort has hitherto been made to find out on what foundations our present industrial structure is built, and what part power plays in it." And one speaker pointed out, very truly, that ancient civilisations failed to advance because they failed to discover new sources of power. The characteristics and utilisation of the different sources of power have been the object of a vast amount of investigation during recent years, and the technical journals are filled with accounts of devices for economising coal, for the utilisation of waste materials or the better use of ordinary fuels, for the conservation of heat, for the economical application of power, such as the wave-impulse process, the mercury boiler, the high-pressure boiler recently described in *Chemistry and Industry*, fuel economisers, pulverised-fuel installations, heat exchangers—the list is unending. But the fundamental problems remain untouched, although the effective use of power for industrial purposes is at the very base of the social structure. Yet our resources of coal and oil are to be considered as wasting assets if we are to believe one branch of opinion, although optimists are not lacking to proclaim that only a fraction of the world's power resources has been tapped. However that may be, we in England will be forced to consider the problem very seriously in a few hundred years. Pictures have been drawn of the migration of industry from the coal fields to districts with water power, of the abandonment and consequent impoverishment of the countries that lack "white coal," as our Gallic friends call hydraulic energy. But it is not easy to foresee economic conditions even a few months ahead, and we cannot pretend to the century-striding imagination of Mr. Wells. Whatever may be the result of the Conference, it cannot but stimulate efforts "amongst the nations in the endeavour to harness the forces of Nature for the common good."

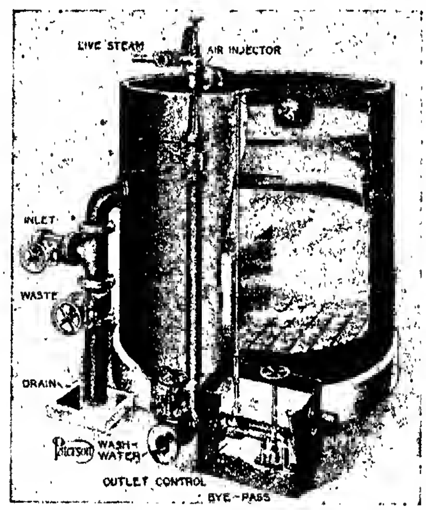
Chemists have a particularly deep interest in the problems of power, whether as motion or heat, apart from the fact that power and labour are two economic factors that have an important influence on the application of chemical processes. The particular aspect of the problem that concerns chemistry is the utilisation of low-potential energy, energy that is developed irresistibly in every hedgerow, in every mossy cranny of the wall, in every flower-decked field. An esteemed clerical contributor has written in these columns about Prof. Baly's work on the synthesis of sugars in the plant, and it is to be hoped that the work is making good progress, for we know so little about the chemical operations performed by living matter. Despite the perfection of modern chemical methods, despite the vast accumulation of chemical data, operations are performed at low temperatures by the vegetable world that are difficult of imitation in the laboratory, and then only at a considerable expenditure of energy and with the aid of elaborate apparatus. Last week Prof. Drummond pleaded for a broader basis in the training of chemists, and remarked how often chemists were faced with the problems of the cell. How beautiful are the processes of the living cell! Who could fail to be impressed when the microscope reveals the amazing process of cell division, when the chromosomes are seen to divide equally, arrange themselves symmetrically, one-half at each end of the cell, when the formation of the dividing wall becomes apparent, to be followed by the separation of two cells where there was but one before. We have no explanation of this mysterious activity, we cannot imitate it, but we can be confident that an explanation will be found. Prof. Irvine and his co-workers are unravelling many twisted threads in the chemistry of the carbohydrates, Prof. McBain has inspired an active school of research in colloid chemistry, and at Liverpool, those members who attend the Society's Annual Meeting, will be able to see Prof. Baly in the flesh and to acquire fresh knowledge about the syntheses in the plant cell. Pessimism leads nowhere, optimism is too often blind, but we are confident that the future holds a vast treasure of knowledge that will be won and distributed. Sir William Pope has thought much about these matters, and it is of interest to quote from his recent Cantor Lecture: "Fears are often expressed that humanity is being impoverished, and that posterity will be embarrassed by the rapidity with which our coal and petroleum resources are being consumed; but it is reasonable to presume that long before these potential supplies of energy have disappeared, their applications will have become obsolete. Whilst every motive exists for employing our present sources of energy with the maximum efficiency, we may safely leave posterity to look after itself with the aid of its scientific heritage." How fortunate will be the chemist who arrives at an understanding of the mechanism of chemical changes, particularly of catalytic reactions such as occur in living matter; he will have his fingers on the very pulse of life. We cannot tell whither we are going, but chemistry is preparing the road to the future.

INDUSTRIAL FILTRATION PART II

By S. G. URE, M.A., B.Sc.

Sand Filters

Sometimes the water supplies to factories contai impurities which can be removed either directl by filtration or precipitated by treatment wit suitable materials and then filtered. The type c filter usually employed in this class of work is th sand filter. One plant of this type made by th Paterson Engineering Co. consists of a cylindrica steel vessel having dished ends placed with it axis vertical in the smaller sizes, and horizonta in the larger units. A layer of pea gravel is spreac on the bottom of this vessel and over this is placec the filtering medium consisting of a thick bed o quartz sand. To prevent disturbance of the uppe surface of the sand and to ensure an even feed

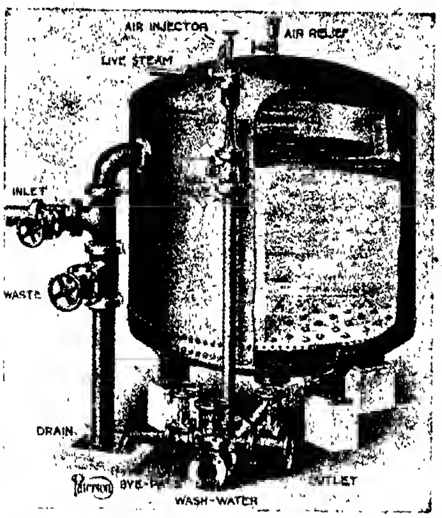


Paterson Gravity Filter

Fig. 1

the water enters through a trough situated near the top, and riveted to the inside of the cylinder The water, after flowing down through the sand, is collected by a manifold strainer system and leaves the filter through an inspection box. These filters may be of the gravity or pressure types illustrated in Figs. 1 and 2. As the rate of filtration with this system is fifty times that obtained with the slow sand filter, it is evident that for successful working efficient means of cleaning the filtering medium must be installed. In the smallest types this is done by passing a current of water in the reverse direction through the sand which meanwhile is agitated by stirrers operated by a hand wheel on the top of the filter, whilst in the larger sizes the agitation of the sand bed is effected by compressed air. When cleansing the filter the water level is lowered to the level of the inlet trough.

he main inlet and outlet valves closed, and com-ressed air admitted at the bottom of the filter, which thoroughly agitates the sand and loosens the ntercepted impurities. The impurities are washed ipwards by a current of water, also admitted at he bottom of the filter and are collected and emoved through the annular trough. The cleansing nd aeration of the bed can be accomplished in a ew minutes, and on the filter being again put into ommission an automatic outlet control causes his to take place gradually, thus ensuring a filtered lischarge. When very large units are desired, iorizontal cylinders are employed, as it is found hat in the vertical type, dished ends greater than ft. in diameter cannot withstand the pressures.



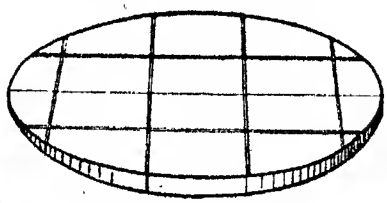
Paterson Pressure Filter

FIG. 2

The coagulation of very finely divided particles is effected by the addition of small quantities of sulphate of alumina which, reacting with the calcium carbonate, either present in or added to the water, forms aluminium hydrate, which brings down the suspended matter. The firm provides an automatic coagulant-supply gear, which adds the correct amount of coagulant to the varying volumes of water passing through the filter.

Porous Plate Filters

In filters of this class made by S. Bornett and Co., Ltd., and illustrated in Figs. 3, 4 and 5, the filtering medium consists of porous plates, made of carbon, silica, fireclay and siliceous clay. Such filters are capable of handling acid, alkaline, corrosive, hot and volatile liquors. In its simplest form the filter is made by placing a number of these bricks suitably shaped in the bottom of an earthenware cylinder, as shown in plan in Fig. 3. At the lower corners of these plates are projections, which keep the plates clear of the bottom of the cylinder and so provide a collecting space for the filtered liquor. The upper edges of the plates are bevelled, so that when two plates are in contact, a V-shaped groove is formed, which can be filled with a suitable jointing material, such as portland cement, lead, or a mixture of sulphur and graphite. The unfiltered liquor is admitted above the porous plates, and is filtered



Arrangement of Porous Filter Plates for Bornett Circular Vacuum Filter

FIG. 3

by its passage through them. Porous plate filters work either under vacuum, but usually under pressures greater than atmospheric. The smaller sizes, illustrated in Fig. 4, consist of a vertical cast iron cylinder, provided with a hole in the bottom, and fitted with a swing cover on the top. Into this cylinder is placed a stoneware cylinder open at the top, and having a central outlet pipe at the bottom which passes through the hole in the bottom of the outer

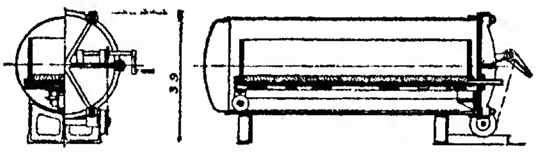
Bornett Pressure Filter, 20-gallon Pot Type

FIG. 4

cylinder, the joint between the outer and inner cylinder being formed by a rubber ring, which fits tightly over the outer surface of the outlet pipe. The porous plate is fixed near the bottom of the stoneware cylinder, which is then filled with the liquid to be filtered. The cover of the outer cylinder having been put into position, and screwed down, com-

pressed air is admitted to the cylinder, and forces the liquid through the porous plate, and at the same time compresses the rubber ring between the bottom of the cast iron and the bottom of the porcelain cylinders, thus forming an airtight joint. In the larger sizes (Fig. 5) the cast iron cylinder is horizontal, and a number of rectangular troughs, suitably dimensioned to fit the cylinder, are attached to the cover. This cover is mounted on a trolley, to facilitate the insertion or withdrawal of the troughs from the cylinder, and the inner ends of the troughs are fitted with wheels, which, running on rails attached to the wall of the cylinder, prevent tilting. The troughs are provided with a double bottom made of porous plates cemented together. Outlet pipes communicating with the space between



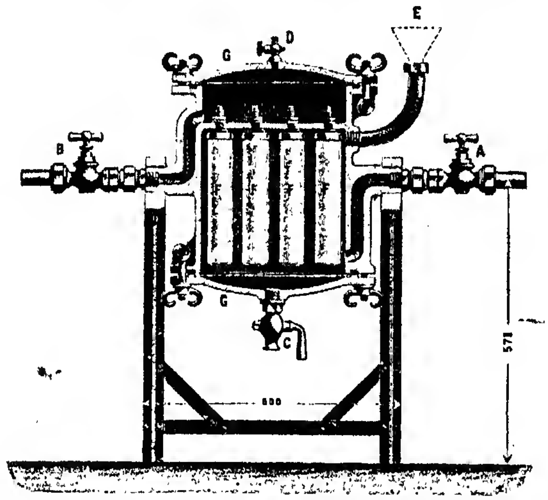
Bornett Pressure Filter
Capacity 50 Gallons an Hour

Fig. 5

the porous plates and the bottom of the trough pass through the movable cover, and are then connected to the tank for reception of the filtered liquor. The leakage of air round those pipes is prevented by suitable stuffing boxes and glands. In operating the machine, the troughs are withdrawn from the casing and filled with the liquid to be filtered. They are then run into the cylinder, and after the cover has been screwed up, compressed air is admitted to the cylinder, the filtered liquid being removed by the outlet pipes, which can if desired deliver the liquid into a receiver placed on a higher level than the filter. After filtration, if washing of the precipitate is necessary, the troughs may be withdrawn, filled with water, and again returned to the cylinder. Compressed air is again applied, to force the wash water through the precipitate on the plates. After washing, the air is released and the troughs withdrawn to enable the precipitate to be removed. Filtration can be made continuous instead of intermittent by running in the liquid from overhead receivers under pressure and washing or extraction can be carried out in a similar manner without withdrawing the troughs in the manner described. The following figures give an indication of the rates of flow obtained with filters of this type :—

Material	Thickness of cake in.	Working pressure in lb. per sq. in.	Flow in litres per sq. metre per hour
Calcium chloride	3	30 lb.	200 to 250
Magnesium carbonate ..	3	Vacuum	200
Photographic chemical ..	1½	60 lb.	150
Silicic acid..	1½	Vacuum	145

In the Berkefeld filter, illustrated in Fig. 6, the filtering medium consists of carbon or kieselguhr candles cemented into metallic caps having central outlet pipes. These candles are suspended by their outlet pipes from a plate placed at right angles to the axis of the cylindrical containing vessel. This plate divides the cylinder into two compartments the lower one of these containing the filter candles The liquid to be filtered is pumped into this compartment, and in its passage to the upper compartment must flow through the filtering medium The outlet for the filtered liquid is attached to the upper compartment. In using the filter a fine coating of kieselguhr is first deposited on the outside of the candles, by mixing kieselguhr with the



Section of Berkefeld Filter, Large Size, Pattern T

Fig. 6

incoming water. After a suitable layer of kieselguhr has been formed, the liquid only is admitted to the lower compartment, and filtration is continued until the rate of flow falls off owing to the accumulation of impurities on the filtering surface When this occurs, the filter is cleaned by passing water in the reverse direction through the filtering medium. This water washes off the kieselguhr deposit and the impurities collected thereon, and these can be removed through a cock at the bottom of the filter.

Bag Filters

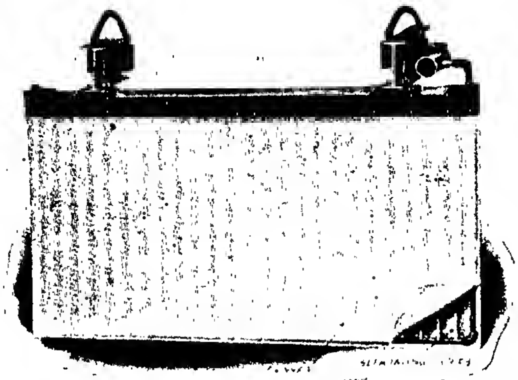
An early form of filter consisted of a number of bags made of muslin or cotton wool. The open end of each bag is attached by means of a metal fitting to short pipes projecting downwards from a trough or launder. The liquor to be filtered is fed into the launder, and entering the bags suspended underneath, flows outwards through the filtering medium whilst the precipitate is retained in the bag. Filters of this type can be made having a very large filtering surface but can only be worked at low pressures. When filtering hot liquors, in order to retain the heat, the bags are enclosed in a steam-heated cast iron chamber. This type of filter was largely used in sugar refineries and is still employed in the filtration of gases obtained from furnaces smelting lead and zinc ores. In this

case bags 18 in. in diameter and 30 ft. long are used. These are usually made of wool, as this material resists the heat and acid fumes better than cotton.

Leaf Filters

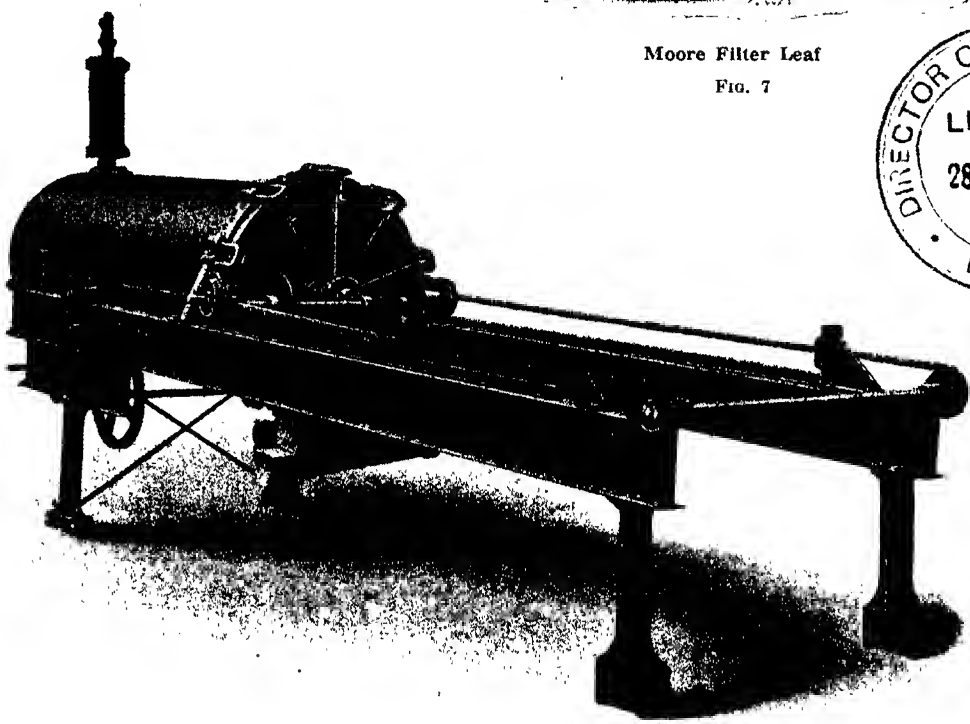
Filters of this type may be divided into two classes, namely, suction and pressure leaf filters. Suction leaf filters were originally introduced to filter the slimes obtained by treating fines with cyanide to extract gold. The filter (Fig. 7) is built up of a number of leaves, each leaf consisting of a filtering medium in the form of a bag, which envelopes a rectangular frame usually made of perforated pipes. Inside this frame and rigidly attached to it is a stiff corrugated surface made of coconut matting, wood or iron. This prevents the collapse of the walls of the bag when suction is applied internally, and at the same time allows the liquor which passes through the filtering medium to reach the outlet placed at the top of the leaf. A filtering unit is formed of a number of parallel leaves rigidly suspended from a series of cross girders. The distance between the leaves depends upon the economical thickness of cake required, but is usually not less than four inches.

The outlet pipes from the leaves are coupled to a collecting pipe, which is connected with a receiving tank, by a piece of flexible tubing, of such a length that it will permit of the unit being immersed in the furthest tank. In working this filter, the unit or battery of leaves is lowered into a tank, containing the liquor to be filtered, and then suction is applied by means of a vacuum pump connected with the receiver from which the filtrate can be removed by a suitable pump or barometric leg. When sufficient



Moore Filter Leaf

Fig. 7



Hand-operated Kelly Filter, ready for Filtering

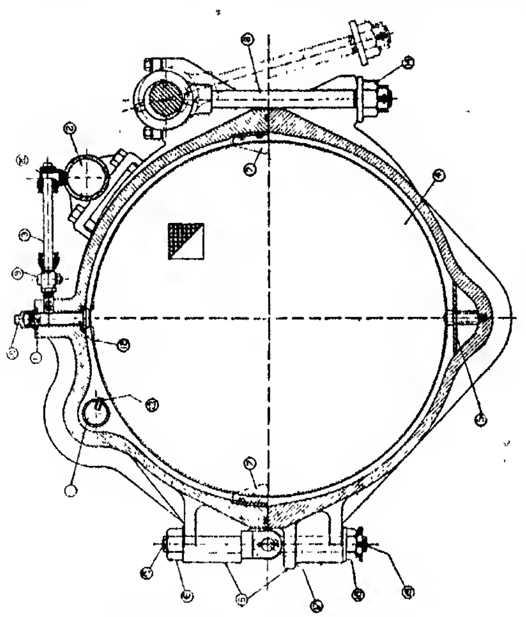
Fig. 8

thickness of cake has been built up, it can be washed by immersing the battery of leaves in a second tank, containing water, and again applying suction to the leaves. If the cake has to be dried, the battery of leaves is removed from the wash tank, and a current of air is drawn through the cake. To remove the cake, compressed air or steam with or without the aid of an externally applied jet can be used, or the leaves may be immersed in a tank of water and a reverse current of water employed. A travelling crane carried on a suitable track above the tanks is used to transport the batteries of leaves from one tank to another. Smooth running must be an essential feature of this crane, as jerky motion is liable to dislodge the cake, and so nullify subsequent washing or drying operations. Special attention should be given to the method of attaching the battery of leaves to the crane, to ensure that the pull exerted by the crane is directly over the centre of gravity of the battery of leaves. During transportation, suction should be applied to the leaves to prevent displacement of the cake. For efficient working, the filtering surface must be kept continually immersed in the liquid, or wash water, and this is accomplished by admitting the liquor or wash water to the tank at a faster rate than can be dealt with by the filter, and removing the excess through a weir at the top of the tank above the filtering surface. Filters of this type are made having a filtering surface of 10,000 square feet, and with this size of filter, the crane may be required to handle loads of about 20 tons. As, however, this is a low pressure filter, the maximum filtering pressure being always less than atmospheric, thus necessitating very large filtering surfaces, pressure leaf filters have been introduced. Belonging to this class are the Kelly and Sweetland filters made by the United Filters Corporation, and the Vallez Filter, manufactured by the Vallez Rotary Filters. The Kelly filter (Fig. 8) consists of a number of rectangular leaves of analogous construction to those used in suction filters, placed parallel to one another, and to the axis of a surrounding cylinder. To obviate the necessity of a crane, involving considerable head room, for the removal of the leaves, the axis of the cylinder is only slightly inclined to the horizontal; the withdrawal of the leaves through the lower end of the cylinder being thus assisted by gravity. In the twin unit type, however, the axes of the cylinders are horizontal, the movement of the leaves being effected by a motor driven mechanism. The leaves are attached to the cylinder cover, the outlet pipes passing through the cover, and then being coupled to the discharge pipe. The other ends of the leaves are attached to a horizontal bar carrying two small wheels, which run on rails fixed one on each side of the inner surface of the cylinder. The cylinder cover is also carried by a frame mounted on wheels, which travel on rails extending from the cylinder. In this way the cover and leaves can be easily withdrawn from the cylinder, to permit of the removal of the cake. The tightening of the joint between the cylinder and cover is effected by a series of radial arms carried on the cover. These engage in a series of U bolts fixed to the cylinder in such a way that by binding on an inclined surface they press the cover against the flange of the cylinder. These radial arms are connected at their inner ends to the actuating mechanism which operates them all simultaneously.

Mounted on the outside of the cylinder are the valves for controlling the admission of the liquor to be filtered, and the wash water, an automatic compressed-air regulator, an air release valve and a drain cock. In operating the filter the relief valve is opened until the filter chamber is filled with the liquid being filtered. On closing this valve the pressure rises inside the filter and filtration begins, the pressure being maintained constant by the incoming liquid. When the desired thickness of cake has been formed the unfiltered liquor in the cylinder is returned, through the drain cock to the storage tank. Whilst this is being done, the cake is held in position by compressed air admitted through the automatic air regulating valve. If, after draining, washing is required, the wash water is pumped into the cylinder, and as its level rises in the chamber, air is released in such a manner that a positive pressure is maintained on the cake. When the cylinder is full of water, the condition will be similar to that existing at the end of filtration and washing can begin. Unfortunately, this operation requires considerable skill and care, as a fall in pressure is liable to crack or break the cake and so cause uneven washing. To overcome this, water containing unwashed cake from previous runs or inert clays is sometimes used to fill up any cracks or holes which may be formed during the transition stage. When it is necessary to dry the cake, the liquid in the cylinder is again drained off through the drain cock, the cake being again held in position by a positive pressure produced by compressed air. After all the liquid has been removed from the cylinder, the air is allowed to flow through the cake and escape through the outlets of the leaves. Here, again, care must be taken to prevent the cake from cracking or breaking. To discharge the filter, the air pressure is released, the cover unlocked, and then drawn as smoothly as possible out of the cylinder. The outlets of the leaves are then closed, and air at about 10 lb. per square inch pressure is admitted into the interior of the leaves. Higher pressures are not used, as they are liable to injure the filter cloths. The efficiency of this process is again lessened by the presence of cracks or holes in the cake. For efficient working of the filter the cakes on two adjacent leaves should not touch each other. Where economy of floor space is essential the twin unit type can be adopted. This consists of two cylinders with their axes in line, and having a space between them equal to the length of the cover and leaves, when fully drawn out from the cylinder. Into this space the leaves are drawn, alternately from each cylinder, in order to remove the cake.

The Sweetland filter (Fig. 9) as at present designed consists of a cast-iron cylinder permanently closed at either end and divided longitudinally so as to form two equal portions. The axis of the cylinder is horizontal, and the upper half is rigidly attached to columns supporting the machine, whilst the lower half is hinged to the upper, in such a way that it can

swing through an angle of at least 90°. Counterbalance weights attached to this portion facilitate its rotation into the shut position. The closing of the joint between the upper and lower halves of the casing is effected as follows. Rigidly attached to the upper half and having its axis parallel to the axis of the casing, is a shaft carrying a number of eccentric sheaves. The straps of these sheaves are each connected to a rod terminating at its lower end in a bolt head. These rods swing into slots formed in the outer flange of the two portions of the casing, the heads being in contact with the lower flange. A hand wheel operat... ...rain of toothed wheels rotates this shaft, and t... raises or lowers the rods,



Cross-section of Sweetland Filter

Fig. 9

thereby applying or releasing the pressure on the joint. A passage is cast in each portion of one of the ends of the filter, in such a manner that when the casing is closed one complete passage is formed, having its inlet on the outer surface of the upper half and its outlet at the lowest point on the inner surface of the lower half. The inlet pipe is bolted to the inlet to this passage, the outlet of which discharges into a duct cast in the lower half of the casing. This duct is covered by a distribution plate through which the liquid is discharged evenly between the leaves throughout the length of the filter. Drain cocks are fitted at the lowest points of the lower half of the casing. The leaves of this press are circular and of such a diameter that they fit closely against the inner surface of the casing. They are attached to the upper half of the casing by the outlet pipes, which, starting from the highest point of each leaf, pass through the highest points of the upper casing and discharge through sight glasses into a common collecting pipe. Lugs cast at the lowest points of the upper half of the casing space out the leaves and prevent them from rotating. A channel cast near the highest point of the upper half of the casing carries a steel pipe parallel to the axis of the filter. This pipe is capable of slight longitudinal as well as rotational motion, and carries a number of nozzles, through which flows the water required for sluicing the cake off the filtering medium. The method of operation of this filter is analogous to that employed on the Kelly machine.

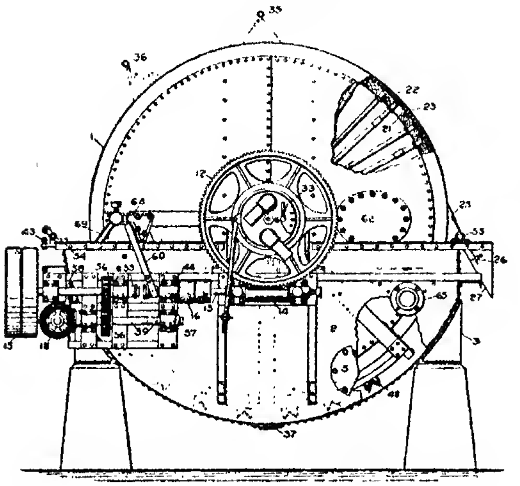
When extra agitation of the liquor being filtered is necessary, some of it is allowed to escape from the filter through the sluicing pipe mentioned above.

The housing of the Vallez filter is also cylindrical, and cast in two portions, which are bolted together, giving a longitudinal joint. The axis of this casing is horizontal, and as it does not require to be opened for the removal of the cake a permanent joint can be made after the filtering surface has been put into position. The filtering surface is formed of a series of cloth-covered discs which are keyed to a stout hollow shaft. The discs are provided with hollow hubs which regulate the spaces between the discs. The hollow portion of the hub communicates with the drainage area behind the cloth, and by means of radial holes in the shaft, with the hollow portion of the shaft. Four angle irons attached to the peripheries of the discs maintain their alignment, and at the same time remove any solid material from the wall of the casing. The shaft is carried by bearings in the end plates of the casing, leakage past these bearings being prevented by suitable stuffing boxes and glands. One end of the hollow shaft is plugged and fitted with a worm wheel which engages with a worm, through which rotational motion is given to the shaft and leaves. The other end of the hollow shaft is fitted with a stuffing box and gland through which passes the outlet pipe for the removal of the filtered liquid. At the lowest point of the casing is a trough which contains a screw conveyor, by which the cake is carried to the discharge boxes. At the highest point of the casing is a second channel containing a pipe having a series of nozzles so arranged that they can direct streams of water or air over the filtering surfaces of the discs, and so remove the cake, which is then carried by the above mentioned angle irons into the lower trough. Suitable openings at the bottom of the filter-casing admit the solution to be filtered, the water for washing the cake, and steam if required, and permit of the removal of the surplus liquor and wash water. A small cock at the top of the filter provides a suitable vent for the air displaced by the incoming liquid. When the air has been displaced, the pressure inside the cylinder rises, and forces the liquid through the filtering medium. The rotation of the discs keeps the liquor thoroughly agitated, and ensures a uniform deposit of cake. This machine is also provided with an ingenious device by which the thickness of cake can be directly measured. After formation of the cake, the liquor is drained off, the cake being meanwhile held in position by a positive pressure created by the admission of compressed air to the filter. If washing is necessary, this air is gradually displaced by wash

water, care being taken to prevent fluctuation in the pressure on the cake. After washing, the surplus wash water can be again drained off, and if necessary, the cake can be dried by compressed air before it is blown off the leaves by the compressed air admitted through the top manifold pipe. These pressure filters require skilled attention, to prevent the cracking and breaking of the cake during the removal of the surplus liquor and wash water.

Continuous Filters

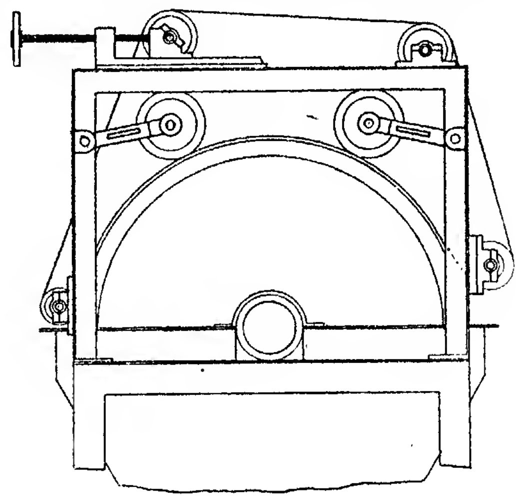
This type of filter is suitable for handling free filtering materials at such temperatures that the vapour pressure does not greatly reduce the vacuum employed. Filters of this class may be divided into



Oliver Filter with Oscillating Agitator and Enclosed Heads

Fig. 10

two types, namely, the drum and the disc type, and although the former has been in use for a considerable time, its modern development only dates from 1908, when the Oliver filter (Fig. 10) was invented. This filter consists of a hollow drum, which rotates on a horizontal axis. The outer surface of this cylinder is divided into a number of independent and separate compartments by partitions placed parallel to the axis of rotation. Supported by the outer edges of these partitions is a screen, upon which rests the filtering medium, in the form of a continuous sheet. Each compartment has two outlets, to facilitate drainage, one on the leading, and the other on the lagging side of the compartment. These two outlets are coupled to one pipe, which, passing through one of the trunnions supporting the drum, terminates in its own port on the end of the shaft. The valve consists of a hollow cylindrical casting, on the inner face of which is an annulus which coincides with the ports on the end of the shaft. A number of radial walls divide the cylinder into a number of compartments, the outlets of which are formed by holes drilled in the outer end of the valve. Adjustable bridge pieces are fitted into the annulus, so as t isolate the group of ports in communication with or chamber of the valves, from the groups of ports i communication with the chambers on either sid The shaft of the drum rests on bearings mounte on the upper edge of a tank which is provided with suitable agitating device, and contains the liquid t be filtered, which thus covers the lower portion of th drum. The lowest chamber of the valve, whic remains stationary, is connected to a vacuum pump and in this way a suction is applied to those com partments of the drum immersed in the liquid. Th filtered liquor drawn into this chamber can be caugh in a receiver, placed in the pipe line leading from th chamber to the vacuum pump, and can be withdraw from this chamber, by another pump, or barometri leg. As the drum rotates, those compartments after passing the first bridge, come one by one int communication with the second valve chamber i which a low vacuum is maintained. During th time that the compartments are in communication with this chamber of the valve, the cake is washed by water applied in the form of a fine spray. The compartments of the drum during this period are ascend-



Sketch of end view of FEinc Filter

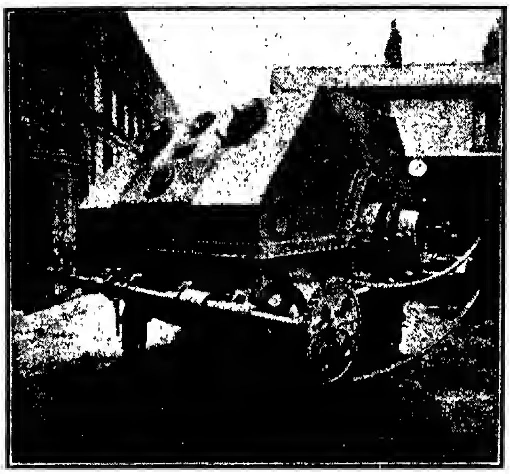
Fig. 11

ing from the upper edge of the tank to their highest position. During the descent of these compartments from their highest position their ports pass the second bridge and come into contact with a third chamber of the valve in which also a low vacuum is maintained By this means air is drawn through the cake to dry it Just before the compartments of the drum reach the level of the upper edge of the tank, their ports pass a third bridge piece, and bring them one at a time into contact with a fourth valve chamber containing compressed air, which loosens the cake, and causes it to be easily removed by a knife or scraper, placed parallel to the axis of the drum and a little above the upper edge of the tank. Further rotation of the

drum causes the ports, to pass the fourth bridge piece, and to come again into communication with the first chamber of the valve, just as the corresponding compartment is again submerged in the liquid in the tank. The compartments of the drum then repeat the cycle described above.

To obviate the use of an atomised spray for washing purposes, and at the same time to compress the cake and provide a new method of removal from the drum, the Filter Engineers Incorporated have developed the FEinc filter shown in Figure 11.

This consists of a drum filter similar in action to the one described above. Over the upper surface of the drum from the liquor level to the point of removal of the cake passes an endless belt made of a porous material such as wool or cotton. This belt extends over the full length of the drum and is carried by four pulleys mounted on a frame work



Kestner Continuous Filter
Fig. 12

attached to the top of the tank. Sometimes idle rollers resting on the top of the belt whilst in contact with the cake, are used to compress the cake on the drum. When the cake has to be washed, the wash water is applied as a stream on the upper surface of that portion of the belt in contact with the cake. The objects of this device are to prevent cracks developing in the cake, and so reduce the capacity of the vacuum pumps required, to deliver drier cakes, to cause the cake to be discharged as a sheet on the application of compressed air and to eliminate nozzle troubles and pumping plant required for atomising the wash water.

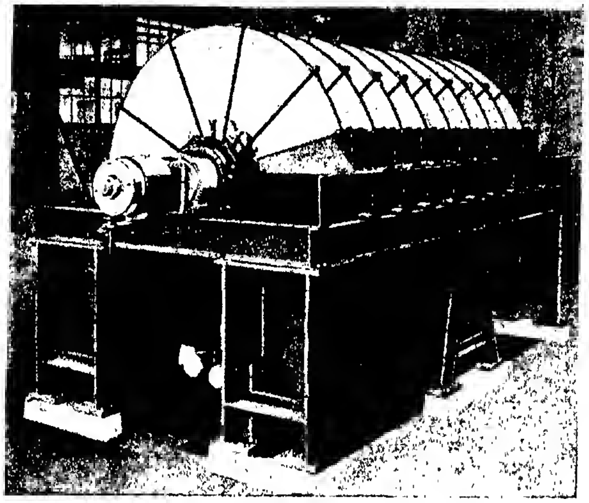
The Kestner Evaporator and Engineering Co., also manufacture a continuous filter of the drum type illustrated in Figure 12, which can be used for filtering volatile liquids. In this plant the drum is totally enclosed in a vapour-tight chamber by means of a metal cover fitted to the top of the liquor tank. The precipitate is scraped off the drum in the usual way and falls into a trough in which is a conveyor which carries the precipitate to suitable discharging boxes. In the bottom of the liquor tank is an agitating gear driven from a crank shaft mounted inside the cover of the machine

Bevel gearing and chain drives are used to transmit motion from the drum shaft to the conveyor and mixing shafts. The discharge of the vacuum pump is connected to the top of the cover of the filter. In this way any vapour which passes through the filtering medium is returned to the filter, thus maintaining the pressure within the casing at or about atmospheric, and at the same time preventing the loss of valuable vapour. Filters of this type are being used for filtrations of volatile oils, in which case the filtering medium is made of cotton cloth. Messrs Kestner also make an open-type filter for non-volatile liquids which is of similar design, except that the air-tight covers on the drums and conveyors are dispensed with.

Another type of continuous filter, manufactured by the United Filters Corporation and known as the American Continuous Filter, is illustrated in Figure 13. In this machine the filtering surface is made up of a number of equidistant parallel discs mounted on a horizontal shaft. Each of these discs is made up of a number of sectors formed of wood or cast iron and suitably grooved to give efficient drainage, and covered with the filtering medium. The shaft carrying these discs contains a series of equidistant holes, termed filter channels drilled parallel to its axis. The number of these holes corresponds with the number of sectors constituting a disc. An outlet pipe at the inner end of each sector connects the drainage area with one of these filter channels. Radial bolts are also used to fix the sectors in position. The filter channels are connected at their outer ends to a corresponding number of radial ports formed in a conical bush. Inside this conical bush fits a conical plug divided up by bridges into a series of compartments within which are maintained the vacuum required for filtration, washing and drying, and the compressed air required for removal of the cake from the disc. The outlets of these compartments are formed in the outer end of the plug.

This plug and its conical bush constitute an arrangement similar to the standard plug cock, but in this case the plug remains stationary whilst the bush or seat revolves. Tightness between the rubbing surfaces is maintained by the action of a spring on the plug. The disc shaft is carried on bearings mounted on the liquor tank in such a manner that the lower portions of the discs will be immersed in the liquor contained in the tank. The tank itself has on the discharge side of the machine a number of troughs each a little wider than the thickness of a disc, and so arranged that each trough encloses one lower quarter of a disc, the other lower quarter of the disc extending into the open portion of the tank, which does not restrict the thickness of cake formed and permits of good circulation of the liquor being filtered. The cake is removed by radial scrapers and falls through the spaces between the troughs into a hopper. Wash water can only be applied to the cake in the form of a fine spray and great care

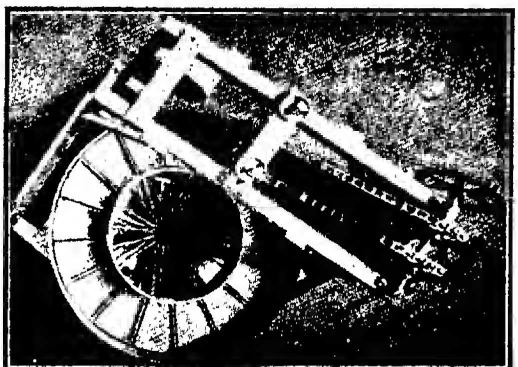
has to be taken to ensure its uniform distribution over the filtered material. This type of machine has a greater filtering surface than that obtainable with the drum type of plant occupying the same floor space.



American Continuous Vacuum Filter

Fig. 13

For handling coarse and granular products it is found that filters of the above types are unsuitable and this has lead to the development of the Oliver Continuous Plane Filter, illustrated in Figure 14. This plant consists of a horizontal annular trough divided by a number of radial partitions into a series of compartments. Each of these compartments



Aeroplane View of Oliver Sand Table Filter

Fig. 14

is covered over the top with the filtering medium which is carried on a suitable supporting surface. The lowest point of each compartment is connected to its own port on an Oliver automatic valve, whose axis coincides with the axis of rotation of the annulus. A rail fixed to the bottom of the annulus and resting on rollers maintains the trough in a horizontal position during rotation. A scraper which works in conjunction with an elevator collects and removes the cake from the filtering surface. After the filtering surface has passed this scraper a fresh lot of liquor to be filtered is uniformly distributed over the surface. During this operation suction is applied to those chambers over which the liquor is being distributed thus removing the liquid and leaving the precipitate on the filtering medium. As the wheel rotates this precipitate passes under the wash water sprays, the compartments underneath being again under suction to draw the wash water through the cake. After passing the washing zone, suction is still applied to these chambers to draw air through the cake to dry it. Before reaching the scraper, compressed air is admitted to the chamber thus loosening the cake from the filtering surface and facilitating its removal by the scraper.

(*To be continued*)

MAGNESIUM SULPHATE IN CANADA

A comparatively new industry has contributed to Canada's mineral production within the past few years as the deposits of magnesium sulphate (Epsom Salts) have been proved and production started on a commercial scale. The alkali deposits which occur in numerous localities in the prairie provinces contain appreciable percentages of magnesium sulphate and it is possible that from these occurrences commercial magnesium sulphate will soon be recovered as a by-product in the production of sodium sulphate. In addition to these deposits there are three known deposits in British Columbia, one of which is being operated at the present time.

The Mines Branch of the Department of Mines is investigating these deposits, in connexion with the examination of the sodium sulphate areas in the prairie provinces.

A deposit of magnesium sulphate occurs in Spotted Lake, B.C., a slight depression in which is a partially dried up lake containing considerable quantities of hydrous magnesium sulphate crystals and saturated brine. Approximately 1600 tons of crude magnesium sulphate have been recovered so far.

The Basque Chemical Company is operating a series of five lakes situated 15 miles west of Ashcroft British Columbia. From these lakes they are excavating crude magnesium sulphate (Epsom Salts) which is shipped to Vancouver where it is refined and sold as medicinal salts, and for tanning purposes. Plans are now under way for greatly extending the development of this deposit.

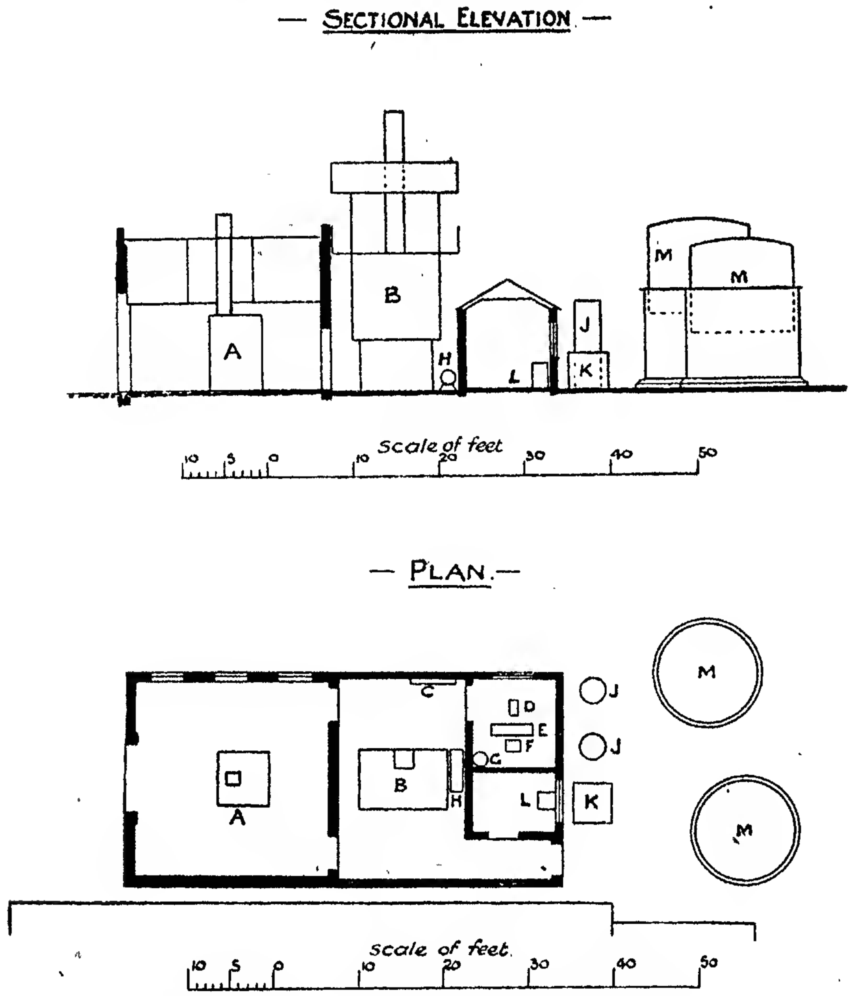
There is a small lake one mile south of Clinton, British Columbia, from which a small tonnage of magnesium sulphate was obtained; and, as the market increases, it may be possible to develop an export trade from Vancouver.

EXPERIMENTAL GAS PLANT IN THE UNIVERSITY OF LEEDS

SIR CORBET WOODALL MEMORIAL

In September, 1917, Mr. Henry Woodall, Junior, made the generous offer to erect and hand over to the University of Leeds an experimental coal gas plant in memory of his father, the late Sir Corbet Woodall, D.Sc. This offer was gratefully accepted by the Council of the University in November, 1917, but the conditions prevailing at that time prevented the carrying out of the project. When circumstances became more favourable, Mr. Henry Woodall commenced operations, and the plant is now complete and ready for use, the scale of the scheme for plant and fund connected therewith having been meanwhile extended by other donors who desired to be identified with Mr. Woodall in this work.

It stands on a site provided by the University adjoining the Department of Coal Gas and Fuel Industries. Mr. J. F. Scott, A.M.I.C.E., has been the engineer in charge of the layout and construction of the plant, which is housed in buildings erected by Messrs. Banks Mawson, contractors, Leeds. Whilst the plant is arranged for the carbonisation of coal, with recovery and measurement of the usual products, it is not merely a coal-gas plant of normal type on a small scale. It is designed to carbonise coal on a scale greater than is possible in laboratory apparatus, which is apt to yield some products in quantities too small to permit of measurement and examination. At the same time the scale of operation is moderate, so that it will still be possible to



The University of Leeds. Experimental Coal Gas Plant

THE FOURTH CONGRESS OF INDUSTRIAL CHEMISTRY

(From our Special Correspondent.)

The Fourth Congress of Industrial Chemistry organised by the Société de Chimie Industrielle was held from June 15 to 21 at Bordeaux. As in previous years numerous foreign delegates were present, and addresses were delivered at the Congress dealing with two subjects of vital importance to the prosperity of South-West France, namely, Oenology, and the Pine and its Related Industries. All the papers read illustrated the essentially collective work of science, pursued by a multitude of workers of all ages and nationalities, following each other and associated by virtue of a tacit understanding to seek the truth and to apply that truth to the continuous transformation of the conditions of all men (Berthelot).

The Congress opened on June 15 by a gala evening at the Grand Theatre of Bordeaux after which the foreign delegates and members were received in the "foyers," remarkable for their delicate architecture in the purest 18th century style. On June 16, the Congress was formally opened under the presidency of Monsieur Tassel representing the Ministry of the Colonies, supported by MM. H. Gall, vice-president, Jean Gérard, Jean Voisin, Maurice Deschiens and members of the local organising committee. After a welcome by Monsieur Philippart, mayor of Bordeaux, Monsieur Gall outlined the many reasons which decided the Council to select Bordeaux for the meeting.

Monsieur G. Dupont, director of the Institut du Pin then gave an address on *Pinus maritima* and industries dependent on it. After describing the resin-producing districts of France, and the methods of producing resin and turpentine, the lecturer discussed the various industries which could use the products of the pine, and instanced paper-making, varnish, synthetic perfumes, pharmaceutical products, industries making plastic materials and synthetic camphor, lamp black and printing ink, and smaller industries such as soap-making, the making of polishes, dyes, and tanning. In addition pine wood might be used as pit-props and railway sleepers. Monsieur Dupont concluded by stating that France was the second largest producer of turpentine and resin in the world.

In the afternoon of June 16, and on the following days the work of the sixteen different groups of the Société continued regularly. Amongst the many papers presented special note may be taken of those on the Estimation of Manganese in Steel; Considerations on the Electrical Precipitation of Dust; Problems of Solid and Liquid Fuels; The Question of Absolute Alcohol; The Industrial Manufacture of Hydrogen; Sensitometry and the Infra-red in Photography; Turpentine and Wood Pulp from *Pinus maritima*; The Theory and Practice of Wine-making; and Economic Problems. All these articles will appear at a later date in the Journal of the Société.

The visits to works and the excursions provided particularly happy illustrations of applied chemistry. Visits to the shipyards of Bordeaux showed how up to date was French industry, and the inspections of factories making liqueurs, preserving food, and making chocolate were particularly instructive. A visit to the Port of Bassens built on the banks of the Garonne by the United States during the war showed the possibilities of developing the port of Bordeaux.

The closing meeting of the Congress on June 18 was devoted to a paper by Monsieur Lafforgne on "The Production of Wine in the Gironde District." The audience listened enthralled to the account of the cultivation of the vine, its protection against disease and the production of the wine itself, terminating with valuable hints on testing, explaining the merits of the various "grands crus" of the district. The same evening the qualities of the Giroudian wines were tested with appreciation at the banquet, but the day after those present had the fortune to visit the district where are produced the famous Barsac, Sauterne and Graves.

A visit to Arcachon on June [illegible]ated the pine and resin industry, which was seen in its pri[illegible] stages. At Arcachon the visitors saw a new sulphurous spring found during recent borings in search of petroleum. On the way back a visit was paid to the broadcasting station at Croix d'Hins.

The whole congress passed off most successfully, and again showed the vigour and activity of the Société de Chimie Industrielle. The Fifth Congress will be held in Paris in 1925, when the chief addresses will be devoted more particularly to metallurgy.

On May 27, the Fuel Group heard a paper by M. A. Kling on the Bergius process. Monsieur Kling, who has studied the process at Manheim, where the process is being worked, stated that the operation by which Bergius transformed solid fuels of high molecular weight into hydrocarbons of low molecular weight, depended on dissociation, and that the laws controlling the operation should be similar to those simple dissociations, though complicated by polymerisation of the dissociated products. Comparing cracking with the Bergius process, the lecturer said the dissociation of the cracked materials yielded hydrogen and unsaturated molecules which then polymerised, then the polymerised products underwent the same transformation and so on. Cracking thus yielded products of low molecular weight, hydrogen, unsaturated hydrocarbons, and large amounts of carbonised material, which decreased the yields and choked the plant. In the Bergius process on the contrary, cracking under a high initial pressure of hydrogen (200 atmospheres) displaced the equilibrium, the long chains breaking into shorter ones but without yielding unsaturated products, so that there was no carbonaceous residue. The speaker then discussed the validity of the various Bergius patents from the point of view of priority, and after considering laboratory and large-scale results, stated that the process seemed to be sufficiently developed to be applied to liquid or pasty natural products, whereas it was not possible to say whether its application to coal would be advisable.

The Inorganic Group met on June 11, Mr. H. Gall in the chair. A paper was read on "Leucite as a source of alumina, potash and silica," by Baron

G. H. Blanc, who described his process for the treatment of leucite by the acid method, utilised by the Società Italiana Potassa. Leucite thus becomes a most important raw material for the production of alumina and potash. In addition the very pure silica obtained as a by-product has physico-chemical properties which render it of much interest as an industrial material. Another process using an alkaline treatment has been elaborated by M. Gordon, a collaborator of Baron Blanc. (For a full description of the process see the article by Prof. J. W. Hinchley entitled "The Manufacture of Potash and other Salts from Leucite,"—*Chem. & Ind.*, 1924, pp. 158-168).

THE BIOCHEMICAL SOCIETY

A meeting was held at St. Thomas's Hospital on June 16, when the following papers were read:—(i) W. H. Hurtley, "Millon's Reagent." (ii) J. L. Rosedale, "The Amino-Acids of Flesh." (iii) R. H. A. Plimmer and J. Lowndes, "The Transformation in the Calcium Content of the Hen's Egg During Development."

The fourth paper was by A. Hunter and James A. Morrell, on "Some Conditions Affecting the Action of the Enzyme Arginase." The activity of arginase commences at p_H 4·8, rises to a maximum at or near p_H 9·8, and falls then so abruptly that at p_H 11·5 it is practically zero. At a p_H of 7·3 the enzyme has a temperature coefficient of 2·69 for 0°—10° C., 2·32 for 10°—20° C., and 2·13 for 20°—30° C.; the corresponding values for the constant of Arrhenius are 15,300, 14,000 and 13,400. Variations in the concentration of enzyme (E) and substrate (S), if confined within certain limits, have an effect expressed by the formula $ET/S=k$, where T is the time taken to decompose a given fraction of the total arginine. The hydrolysis of arginine by arginase does not obey the law of a unimolecular reaction. Under certain conditions and for limited periods of time the velocity curve has been found to fit the square-root law or the more general formula of Arrhenius.

SOCIETY OF GLASS TECHNOLOGY

The last meeting of the Society of Glass Technology for the session 1923-24 was held in Sheffield, on June 18, the President, Col. S. C. Halse, C.M.G., in the chair. Two papers were presented.

(1) "Some Remarks on the Erection and Operation of Modern Pot Furnaces," by Percival Marson. In the absence of the author this paper was read by Prof. W. E. S. Turner, D.Sc. The author pointed out that the glass manufacturer, before constructing a pot furnace, which represented so heavy a capital expenditure, should have adequate plans prepared. A furnace builder who knew his business should be able to guarantee his furnace, but in any case it was desirable to have a technologist as intermediary in order that suitable specifications might be laid down and adhered to. Amongst other things the builder should study the nature of the ground upon which the furnace was to be erected and he should construct an adequate foundation, providing also any necessary drainage and protection of the flues from ingress of water. The provision of suitable flue dampers with some form of indicator allowed of a more accurate regulation of the furnace during working. A small hole in the furnace above one of the pots served to give an indication, by observation of the issuing flame, of the state of combustion, so that correct conditions could thereby be attained. For a "full crystal" glass a furnace temperature of 1300° was sufficient, and nothing was gained by exceeding this, but for soda-lime glass a temperature of 1400° could be maintained with advantage. It was claimed that for the crystal glass a circular pot was better than an oval or egg-shaped one, since it was less likely to cause cords in the glass.

(2) A "Note on an Unusual Type of Recuperative Tank Furnace," by F. W. Hodkin, B.Sc., and Prof. W. E. S. Turner, D.Sc., was presented by Mr. Hodkin, who gave an account of observations made upon a recuperative tank furnace in operation at the Belindar Works of Messrs. Lax and Shaw, Ltd., Leeds. The observations were made as the result of an invitation extended by Mr. J. S. Shaw to Prof. Turner to inspect the furnace. The main feature of interest was the method of recuperating the secondary air. This air entered by arched passages situated beneath the bottom of the tank and above similar passages conveying the exit gases to the chimney flue. It then passed by means of vertical channels in the working end of the furnace to a space between an upper and a lower crown. After traversing the space between the crowns the air entered the furnace through a series of ports placed so as to have the gas ports between them. Producer gas was admitted, without preheating, through a gas-chamber connected with ports or burners opening into the melting end of the furnace. The flames traversed the whole length of the furnace, the products of combustion escaping through vertical downtakes in the working end to the flues beneath the tank. The batch was charged through an opening at the side of the furnace, and one big advantage claimed for the method of construction was that it permitted of working operations being conducted along the walls, not only of the working end, but also of the melting end, by the use in the latter of syphons. The tank had a double bridge. In other words the bridge had three walls separated by cavities through which steam was blown for cooling purposes. With gas at 700° C., and air at 720° C., the temperature of the glass in the melting end was 1460° C. The production of glass from the tank, which was not being worked at full capacity, averaged 80 tons per week for a consumption of about 60 tons of coal on the producers. This glass was worked by three machines with feeders situated in the working end of the furnace, and by hands from four boots in the melting end. The designers anticipated a production of more than 120 tons of glass per week when working fully.

The President announced that a party of members of the Society was visiting Belgium from July 7 to 12.

CORRESPONDENCE

THE LAW OF SOLUBILITY PRODUCT

Sir,—In reference to Mr. Butler's interesting proof of the law of solubility product (*Chemistry and Industry*. 43, 25, p. 634), I think the usual proof is of more value than Mr. Butler is disposed to admit of.

The usual deduction of this law from the law of mass action is unsatisfactory only in this, that we cannot submit it also to experimental proof, because we do not know the degree of ionisation of strong electrolytes except in very dilute solution, when they are completely dissociated. We, therefore, cannot prove that the law of mass action applies to them.

It is usually made clear to students that calculations on the ionisation phenomena of electrolytes are only valid in the case of very dilute solutions, in which the ions approximate in their behaviour to perfect solutes. To such solutions the law of mass action *must* be applicable whether we are in a position to prove this experimentally or not.

From an educational point of view the fact that the law of solubility product is a necessary corollary of the law of mass action as applied to dilute solutions of electrolytes is of prime importance. Mr. Butler's proof is instructive but should not, I think, replace the usual proof.—I am, Sir, etc.,

Blackburn

ASCARITE

Sir,—The article on "Ascarite," by Mr. Stetzer, which appeared in *Chemistry and Industry* of June 20, was very interesting, as this material seems to possess similar advantages to those we claim for Sofnol Soda-lime G., particulars of which appeared in one of our recent advertisements in the *Journal*.

The introduction of both materials also seems to have been brought about by similar difficulties encountered in the first instance in the laboratory, but, whereas Ascarite was introduced in connexion with steel analyses, Sofnol Soda-lime G. was prepared by us owing to the want of a more satisfactory absorbent in connexion with fuel analysis.

Sofnol Soda-lime G. has a very low moisture content, which eliminates the error due to the presence of water in ordinary soda-lime, and as it contains a certain percentage of manganese, this accelerates absorption and, at the same time, acts as an indicator.

The progress of the absorption can be actually watched by means of the change of colour, you know when the reaction is complete, and can see how much "life" there is still left in the Soda-lime. Hence analyses can be carried out in a minimum of time.

Sofnol Soda-lime G. possesses all the advantages claimed for Ascarite; in addition it is a product of British manufacture and considerably lower in price

—I am, Sir, etc., Sofnol, Limited

L. O. Newton, Managing Director

Greenwich, S.E. 10
June 24, 1924

WHAT IS A CHEMIST?

Sir,—It is high time that chemists studied a little grammar and were reminded that the word "chemical" is strictly an adjective and not a noun. Thus a "chemical" substance is one and individual, and possesses valuable and characteristic properties which are not destroyed by mechanical subdivision. Take a carboy of sulphuric acid. A single tap with a hammer destroys the glass vessel, but the characteristic properties of the contents now become evident.

A chemist is one who maintains himself by his ability to recognise and appreciate the properties of substances coming under the above heading. To revert to our broken carboy, the chemist alone can advise properly in solving the vexatious problem of a quantity of acid spilled on the floor and he only can ascertain the index figure which will lead to estimating the monetary value of the lost acid.

Every man to his profession. The solicitor with his deeds and conveyances, the doctor with his prescription (in the widest sense) for the restoration of health, the dentist with his forceps and drills, the pharmacist with his right to dispense powerful medicines, the auctioneer with his hammer, and so on. But where is the chemist amongst all these? Let him claim his right to be the sole user of a box of standardised weights in ascertaining the properties of "chemical" substances and in directing their movements.—I am, Sir, etc.,

Flint F. Shedden
June 28, 1924

[According to the "New English Dictionary" the word "chemical," though used principally as an adjective, is also used as a substantive, the definition being "A substance obtained or used in chemical operations."—Ed]

OBITUARY

SIR J. J. DOBBIE, F.R.S.

The death of Sir James Johnston Dobbie, M.A., D.Sc., LL.D., F.R.S., lately Government Chemist, occurred at Fairlie, Ayrshire, on the 19th of this month.

Sir James Dobbie succeeded Sir Edward Thorpe in 1909 as Principal of the Government Laboratory, and was the first to hold the position of Government Chemist after that institution had been consolidated in 1911 as a separate Crown Department dealing with chemical matters arising from all Departments of State.

He was born in Glasgow in the year 1852 and educated at the High School and the University there, graduating in Arts with First Class Honours in Natural Science, thereafter, pursuing his duties at Leipzig and in Edinburgh, where he took the degree of D.Sc. He was appointed lecturer in Mineralogy at Glasgow University, and in 1881 was appointed assistant to the Professor of Chemistry there, proceeding in 1884 as Professor of Chemistry to the University College of North Wales at Bangor There he devoted himself to teaching, research and to agricultural education.

As a teacher he commanded the respect of all his students in virtue of his personality, and afforded

encouragement to the senior ones to take up research, for the most part in subjects in which he was interested.

Research on the relation between the chemical constitution and the absorption spectra of chemical compounds, and on the chemical constitution of alkaloids was pursued at Bangor in conjunction with a school of assistants. A large number of papers appeared on these subjects, and in recognition of their value he was elected a Fellow of the Royal Society in 1904.

He was greatly interested in agricultural education into which he introduced new methods, including deductions from field experiments, his services in this direction being cordially acknowledged by the Board of Agriculture.

For six years, from 1903 onwards, he occupied the post of Director of the Royal Scottish Museum, Edinburgh, which under his care and well-known methodical supervision was considerably increased and rendered more effective. During this period also he found time to pursue his researches on absorption spectra and the constitution of alkaloids. He continued his work on absorption at the Government Laboratory, both from the point of view of the constitution of the alkaloids and also to gain information on this property in the case of the vapour of elements heated throughout a range of temperature. In addition, he investigated the constitution of diphenylene and communicated papers on subjects which came before the Laboratory.

His well-known sound judgment and experience led to his appointment as a member of important Commissions and Committees, such as the Royal Commission on Awards to Inventors, and the University Grants Committee. In 1915 his services to science both as an investigator and administrator were recognised by the King, who conferred a knighthood on him, and in 1908 he received the degree of LL.D. from Glasgow University. In 1915 he was President of the Institute of Chemistry and in 1919 of the Chemical Society. His period as Government Chemist covered the difficult years of the War when greatly increased duties were thrown upon him.

The charm of his personality and the unvarying courtesy with which he met everyone are features which come to the mind of all who were acquainted with Sir James Dobbie. The present writer has had occasion frequently to observe the influence of his work in the Government Laboratory, and to note the great affection that all members of his staff had for him.

He was buried on Monday at Largs Cemetery on a hillside overlooking the Firth of Clyde and commanding a view of the low-lying Cumbraes with the mountains of Arran in the distance, a prospect of which he was never tired, as it was that which faced the home where he spent his holidays and his retirement from office.

Sir James Dobbie is survived by his wife, a son and two daughters, of whom one is the wife of Prof. Haworth, of Armstrong College, Newcastle-on-Tyne. The loss during the War of a promising son, who was an officer in the Black Watch, affected him very deeply at a time when his energies were concentrated on the work of his Department. R. ROBERTSON

PERSONAL AND OTHER ITEMS

The degree of D.Sc. of Trinity College, Dublin, has been conferred, *honoris causa*, upon Prof. R. A. Millikan.

Dr. A. L. Stern, of Burton-on-Trent, is retiring after thirty-four years' service with Messrs. Bass and Co., seventeen of which have been spent as head brewer. A native of Birmingham, Dr. Stern was educated at Mason's College, now Birmingham University, and took the degree of D.Sc. of the University of London. He is the author of several papers read before the Chemical Society, the Institute of Brewing and the Society of Chemical Industry.

The annual meeting of the French Association for the Advancement of Science will be held at Liège from July 28 to August 2.

The Commissioners for the Exhibition of 1851 have awarded senior studentships for 1924 to, *inter alia*, Mr. M. Dixon, M.A., for research in biochemistry, on the recommendation of the University of Cambridge, to Mr. R. D. Haworth, M.Sc., Ph.D., for research in organic chemistry, on the recommendation of the University of Oxford, and to Mr. R. W. Lunt, M.Sc., Ph.D., for research in physical chemistry, on the recommendation of the University of London, University College.

At a recent meeting of the Senate of London University, the title of professor of physics in the University was conferred on Prof. O. W. Richardson, D.Sc., F.R.S., in respect of his part-time appointment as director of research in the Department of Physics at King's College. The degree of D.Sc. in chemistry was also conferred upon Miss M. L. V. Gayler.

The Senate of London University has instituted a degree of M.Sc. in the principles, history and method of science for both internal and external students.

Mr. S. G. Blaylock, general manager of the Consolidated Mining and Smelting Co., Traill, Canada, has been awarded the McCharles prize by the University of Toronto in recognition of his work on the production of electrolytic zinc and on the treatment of complex lead, silver and zinc ores.

Messrs. F. W. Dootson, H. McCombie, W. G. Palmer and A. J. Berry have been appointed demonstrators of chemistry in the University of Cambridge. Dr. J. Chadwick has been appointed assistant director of radioactive research in the Cavendish Laboratory, Cambridge.

Mr. H. W. Cremer, M.Sc., A.M.I.Chem.E., has been appointed senior lecturer and chemistry, and Mr. E. W. McClelland, B.Sc., Ph.D., has been appointed demonstrator in chemistry in King's College, London.

The Degree of Doctor of Science has been conferred by the University of Glasgow on Mr. William M. Cumming, lecturer on Organic Chemistry in the Royal Technical College, Glasgow.

The late Mr. A. E. Tucker, analytical chemist, of Sutton Coldfield, left £12,851, net personalty £9765.

The late Mr. W. E. Gilmour left personal property valued at £238,421, the sum of £214,584 representing

his holding in the United Turkey Red Company, of which he was a director.

Meeting of the British Association in Canada

Many distinguished scientists will be included in the 500 members of the British Association for the Advancement of Science who are travelling to Canada, at the end of this month, to attend the annual meeting of the Association which is being held in Toronto. Amongst those who will be there are Profs. E. C. C. Baly, V. H. Blackman, W. A. Bone, Lord Bledisloe, Sir Wm. Bragg, Dr. H. H. Dale, Profs. C. H. Desch and F. G. Donnan, Sir Henry Fowler, Prof. G. W. O. Howe, Sir Wm. Herdman, Principal J. C. Irvine, Profs. J. W. McBain, W. McDougall and J. C. McLennan, Sir Charles Parsons, Sir Robert Robertson, Sir E. Rutherford, Dr. N. V. Sidgwick and Prof. W. W. Watts. On August 6 the President, Major-General Sir David Bruce, Chairman of the Governing Body of the Lister Institute, will deliver his presidential address, the subject of which will be "The Prevention of Disease," specially dealing with experience acquired during the war. The meetings of the sections will commence on August 7 and continue until August 13, and the sectional presidential addresses will include discourses on "Chemistry and the State," by Sir Robert Robertson; "Inter-Racial Problems and White Colonisation in the Tropics," by Prof. J. W. Gregory; "Academic Freedom in Universities," by Principal Ernest Barker; and "Combination in Attacking Farmers' Problems," by Sir John Russell. The members from Great Britain will sail from Liverpool or Glasgow on July 25 and 26. Excursions to various places of interest are being planned, and during the visit to Saskatchewan a session of the Association will be held in connexion with the opening of a new chemical laboratory in the University of that city.

Empire Mining Council

As a result of the Empire Mining and Metallurgical Congress at the British Empire Exhibition, it has been decided to form an Empire council of mining and metallurgical institutions, with the following main functions:—To promote intercommunication between the various interests, to create and maintain a higher standard of technical efficiency and professional status than now exists, to compile, if deemed necessary, a register of British mining and metallurgical engineers, and to convene future congresses.

Winter Oil Seeds in British India, 1923-24

The memorandum received from provinces which contain 98·7 per cent. of the total area under rape and mustard, and 99·1 per cent. of the total linseed area of British India, states that the total estimated yield of rape and mustard is 1,154,000 tons, as against 1,209,000 t. in last year, there being a decrease of 4 per cent. The total area under rape and mustard amounts to 6,134,000 acres, which is 2 per cent. below the finally revised area of last year. The total area under linseed is 3,730,000 acres, whilst the yield is estimated at 462,000 t., as against 533,000 t. last year, or a decrease of 13 per cent. The condition of the crops, on the whole, is reported to be fair.—(*Ind. Tr. J.*, 1924, May 29.)

FRANCE

Reserves of Energy

In a lecture recently delivered in Paris, Monsieur A. Kling, the director of the Municipal Laboratory of Paris, stated that the world reserves of coal amounted to 7400 milliard metric tons, compared with reserves of petroleum exceeding 82 million hectolitres. The speaker did not discuss production of hydroelectric power, as he considered from present conditions that the cost of the electric calorie was still too high for industry in general. France possessed 17 milliard t. of coal, and French water-power could develop 9 to 10 million h.p., but sources of petroleum are scanty. In 1923, however, France consumed 62,000,000 t. of coal, of which 30,000,000 t. was imported, and 29,000,000 litres of fuels of which 27,700,000 was imported. France obviously must investigate every means of economising fuel, and it was with this idea that experiments are being carried out on the development of methods of utilising tidal power, which might yield another 4 or 5 million hydroelectric h.p., equivalent to the saving of 14,000,000 t. of coal. In the consumption of coal at least 50 per cent. was lost in one way or another, and it was desirable that methods of industrial and domestic heating should be closely scrutinised to prevent waste.

The Synthetic Resin Industry in France

During a recent meeting of the Société d'Encouragement, Monsieur G. Kimpflin described the initiation of the resin industry in France in 1896 by Trillat, who laid down the fundamental principles. During the war the bakelite industry developed greatly. After discussing doubts as to the exact constitution of the product, the speaker showed that the importance of the market justified the rapid development of the industry in recent years in France. The present production was estimated at 12,000 t., corresponding to one-fifth of the American output. Such figures offered an interesting comment on possible development of the industry, development due largely to the increasing demand for phenol-formaldehyde condensation products for use in the electrical industry.

The Coal Industry in the Nord and Pas de Calais

Reports from these districts show that whilst the production in the Nord in January, 1924, was 91 per cent. of that of 1913, the output of briquettes and coke was greater than in pre-war years. At Lens, two batteries of 70 Koppée coke ovens are working; two batteries of 42 ovens utilising washed coke, have been re-lit at Dourges, and 100 metallurgical coke ovens are being rebuilt. The coke ovens at Courrières are also to be reconstructed.

Synthetic Ammonia in France

Recently a note was published in this journal (May, 1924, p. 507), on the new French law of April 11, 1924, authorising the establishment of a State factory at the national powder factory of Toulouse, for the manufacture of synthetic ammonia by the Haber process. A consulting commission has just been set up to examine the plans connected with the new factory at Toulouse. Apart from representatives of the Ministries interested, the commission includes Profs. Schloesing and Guichard, Monsieur Pascalis, and Monsieur Fèvre.

UNITED STATES

Research on Colloids

Plans are being considered by the American Chemical Society, the National Academy of Science, and the U.S. National Research Council for the establishment of a National Institute of Research in Colloid Chemistry. A tentative scheme has been worked out for the Institute, and it is hoped to raise a fund of one million dollars as an endowment.

Gelatin and Glue in 1923

The output of glues and gelatin in 1923, as reported to the Census Bureau by 66 establishments, compares as follows with the production in 1922:—

	Pounds 1923	Pounds 1922
Glues of animal origin	109,061,762	94,640,981
Hide glue	64,757,479	57,891,041
Extracted bone glue	24,428,758	8,532,893
Other bone glue	19,875,525	28,217,047
Other glues	39,164,680	41,254,432
Flexible glue	832,784	604,838
Vegetable glue	32,704,321	40,649,594
Fish glue / all other, incl. casein	5,627,575	
Gelatin of animal origin	15,617,060	15,223,669
Edible	13,321,618	13,242,615
Other than edible	2,295,442	1,981,054

Mineral Output in 1923

Preliminary figures showing the output of minerals in the United States in 1923 are as follows:—

			1923	Inc. (+) or Decr. (—) against 1922
Coal	tons	Bituminous	545,000,000	+123,000,000
		Anthracite	95,000,000	+ 40,000,000
Copper	lb.		1,477,000,000	+530,000,000
Gold	oz.		2,485,000	+ 120,000
Iron	tons		40,060,000	+ 13,200,000
Lead	tons		534,000	+ 57,000
Petroleum	barrels		745,000,000	+187,000,000
Platinum	oz.		900	— 100
Silver	oz.		72,610,000	+ 16,370,000
Zinc	tons		623,000	+ 150,000

Potash Output in 1923

In 1923 the United States produced 39,029 short tons of crude potash salts (20,215 t. of K_2O). Of this output 32,254 t. of crude potash (17,982 t. K_2O) was produced from mineral sources and 6775 t. of crude potash (2233 t. K_2O) was produced from organic sources. This output was made by eight companies operating 12 plants. The quantity sold was 35,164 t. of crude potash (19,281 t. K_2O), valued at $784,671. Imports of crude potash into the United States in 1923 totalled 748,101 t. (209,581 t. K_2O), valued at $15,354,755. Of this amount, 712,441 t. of crude potash (194,079 t. K_2O), valued at $10,624,475, was used mainly in the fertiliser industry.

Artificial Silk Industry

From 1,566,000 lb. in 1913, and 8,000,000 lb. in 1919, the output of artificial silk in the United States has risen to 35,380,000 lb. in 1923. Despite this great increase, imports of artificial silk rose from 2,987,775 lb. in 1922 to 3,906,037 lb. in 1923. Imports of raw (true) silk in 1923 were 49,505,581 lb., a decline of over 1 million lb. compared with the previous year.

CANADA

The Carbon Black Industry

The production of carbon black, a material of considerable importance to the printing ink and rubber industries, is practically confined to the North American continent, where large supplies of natural gas are found. At present British requirements, which amount annually to about 10 million lb., are supplied from the United States. Canadian imports from the same source are about 3 million lb. The American carbon black industry is located mainly in West Virginia and Louisiana, but, as many of the gas fields in these States begin to show signs of decline, and conservation becomes more stringent, the industry is seeking new fields. Interest has also been manifested in Canada as a possible source of supply. Ontario and Alberta are the only provinces in Canada possessing large resources of natural gas. According to the Dominion Department of Mines (Ottawa) there are four or five natural gas fields in Alberta where the prospects for the establishment of a carbon black industry might be considered. These fields are the Many Islands field, near Medicine Hat, the Wainwright field, 100 miles east of Edmonton, and the Peace River and Pelican Rapid fields, in Northern Alberta.—(*Ch. Comm. J., May* 16, 1924.)

Pulp and Paper Industry

The St. Regis Pulp and Paper Co., which possesses 37,000 acres of freehold land west of the Godbout River on the North Shore of the St. Lawrence, and 14,000 acres on the Canadian National Railway, near Escolona, Quebec, proposes to erect, this year, a pulp and paper mill at Cap Rouge, near Quebec at a cost of $5,000,000.

The Gulf Pulp and Paper Co., which recently secured a lease of timber limits from the Quebec Government, at Manicougan, on the north shore of the St. Lawrence, will erect a large mill in proximity to the same city. Lord Rothermere, who was in Quebec about the middle of April, is asserted to be the chief holder in this company.

The A.P.W. Paper Co. of Albany, N.Y., are erecting a large sulphite plant at Sheet Harbour, N.S. The woodlands department of this company will be in charge of Frederick A. Gaylor, a graduate of Yale School of Forestry, and recently in the U.S. forest service, and several forestry engineers.

The St. Maurice Paper Co., Three Rivers, Quebec, is installing, in its mill, two new large machines, estimated to cost $2,250,000.

GENERAL

Potash and Superphosphates in Poland

According to a report of the U.S. Commercial Attaché at Warsaw, the Polish production of potash salts in 1923 was 61,494 tons (46,082 t. in 1922), including 22,119 t. of kainit (2520 t. in 1922). The output of salt rose from 295,000 t. in 1922 to 363,307 t. in 1923. There are 16 superphosphate factories, and two more are being built, but only 12, employing 3000 workers, are producing. The output from 6 of these factories is said to be about 67,000 t.

REVIEWS

1. The Manufacture of Sulphuric Acid (Chamber Process), (Lunge-Cumming Series). By W. Wyld. Pp. xii+424. London: Gurney and Jackson, 1924. 31s. 6d. nett.
2. The Concentration of Sulphuric Acid (Lunge-Cumming Series). By John Wilfrid Parkes, M.Sc., A.I.C. Pp. xii+394. London: Gurney and Jackson, 1924. 31s. 6d. nett.

These two important processes constitute the subject matter of Vols. II and III of the Lunge-Cumming series, which have just been published. The two volumes afford evidence of the wisdom of sectionising the subjects, as the rearrangement has rendered it possible for scattered information to be collected, and for new matter to be introduced.

1. At one period towards the close of the European war the supersession of the chamber process was vaguely foreshadowed. To-day, owing to economic considerations, it would appear that for the production of sulphuric acid up to 80 per cent. strength, the chamber system is more firmly established than ever. It will be generally appreciated that the chamber process embraces the Glover tower, sulphuric-acid chambers, and Gay Lussac towers. This combination of plant in turn involves the circulation and distribution of acid, the supply of steam or atomised water and oxides of nitrogen to the chambers. Moreover, the theory of the production of sulphuric acid in the chamber system rightly deserves a place. Generally speaking, the whole gamut, as briefly outlined above, has been suitably treated, and a due sense of proportion has been observed. Many interesting points emerge from a perusal of the first four chapters.

It is remarked on page 3 that "the pillars upon which the chamber is erected must, of course, go down to the rock, as in any ordinary building of considerable height." Whether the foundations should extend to the ballast or not depends essentially (*a*) on the nature of the subsoil; (*b*) on the weight thrown on the foundations, and (*c*) on the provision made so far as the foundations are concerned for the distribution of the weight. Few sulphuric acid plants in this country exert a greater distributed weight per square foot than 10-cwt., when basing on 18-inches depth of acid in the chambers. The weight, however, is not uniformly distributed on each of the columns. Certain columns carry a greater weight than 10-cwt.; others (indeed, the larger number) carry less than 10-cwt.

From foundations we are led to the construction of sulphuric acid chambers, and the methods of supporting the lead. A variety of methods have been proposed from time to time. What needs to be aimed at is such a construction as will afford the greatest unrestricted area for the distribution of heat. The value of the first chapter would have been enhanced had photographs been furnished showing the actual construction of acid chambers, the methods of rearing the side sheets, and the framework used for fixing the top sheets. There will be general agreement with Mr. Wyld when he says that "the *sine qua non* for lower chamber space is ample Gay Lussac capacity." In this connexion it is important that "intensive working" should be defined. On thi subject divergent views are cited. In the 57tl Alkali Report (1920), it is stated that "intensiv working has much to be said for it." On the othe hand, Nemes's statement is referred to, in which h says, "whether it is really more economical to worl at 18 or 9 or 6 cub. ft. per ton of sulphur per 24 hour is a question not finally decided."

About eighteen pages are devoted to a descriptior of plant intended to replace lead chambers, but nc very definite views are expressed as to the developments which are likely to be expected.

There is much interesting matter concerning the construction of Glover and Gay Lussac towers, but no definite attempt is made to place the design on a really scientific basis. It is true that past and existing practice are dealt with in a lucid way. But beyond this Mr. Wyld does not go.

On page 213 there is an obvious error. The lead lining of the first portion of the Glover tower is referred to as "36-lb."; obviously, "16-lb." is intended.

Mr. Wyld is on familiar ground in dealing with the starting of chambers, and the general questions surrounding the operation and control of the chamber process, as also when he discusses the loss of nitre and the purification of sulphuric acid.

The remaining chapters—Nos. 5, 6 and 7—have been compressed into a few pages. They deal respectively with the arrangement of a sulphuric acid works, chamber system, other processes for the manufacture of sulphuric acid, and the applications of sulphuric acid—a chapter affording valuable statistical data.

One or two mistakes appear in the text. On page 183 "cubit" feet should read "cubic" feet, and on page 382 "cuprous" should be "cupreous," Some of the diagrams appear to be below the standard of those of previous volumes.

Apart from these slight defects, the book is a creditable one, and without doubt it will be regarded as the standard work on the subject.

2. This volume is divided into ten chapters, the first two of which deal respectively with an outline of the processes used in concentration, and the properties of ordinary concentrated sulphuric acid. The latter chapter is an admirable one, and contains a wealth of information of a reliable character. In the third chapter, concentration in heated pans and retorts is very suitably treated. No mention, however, is made of the defects encountered in the concentration of arsenical chamber acid in lead pans.

The question of loss of sulphuric acid in the cascade concentration system is largely affected by the question of adequate draught and the tightness of the tiles and insets on which the basins are seated. The concentration of sulphuric acid in a current of hot gases constitutes the subject-matter of chapter four, and here again plenty of useful information has been amassed. The Trepex, Skoglund, Kessler, Perrin, Duron, Gaillard, Gilchrist, and Kalbperry plants are dealt with in turn.

Chapters six and seven have reference respectively to the condensation of sulphuric acid vapours, and the recovery of sulphuric acid from waste acids.

Both chapters are suitably treated, and much valuable information is afforded.

Chapters eight, nine and ten deal with costs and efficiencies, transport of sulphuric acid, and its application. Under "Costs and efficiencies," reference is made to the graphical system of representation instituted by Quinan. One can cull very valuable data from this chapter concerning the relative merits of the various concentration plants. For example, the approximate average efficiency of concentration plants during the war period (1914-1918) is stated as follows :—

Cascade plant, 85/90 per cent.
Kessler plant, 91/93 per cent.
Gaillard plant, 96/97 per cent.

Again, evidence can be found that the Gaillard plant is more economical to work in all respects except fuel consumption than the Kessler plant.

Finally, it may be said that Vol. III, which is well-written and well-illustrated, will certainly constitute a standard work on the subject of acid concentration for some years to come, and Mr. Parkes is to be congratulated on maintaining unimpaired the Lunge tradition.

P. Parrish

Ore Dressing. Principles and Practice. By T. Simons. First Edition. Pp. xvii+292. London: McGraw Hill Publishing Co., Ltd., 1924. Price 17s. 6d.

Quite a number of books on the Dressing of Minerals have been issued within comparatively recent years, and it must, unfortunately, be admitted that the work now under review, the latest addition to the series, must rank in many respects as amongst the least satisfactory. The author has, of course, the advantage of being the latest writer on the subject; in a highly progressive industry like ore dressing new methods and appliances are continually being introduced, and it is hardly too much to say that a book upon the subject is getting out of date whilst it is passing through the press. On the other hand this rapidity of development enables the author of the latest book on the subject to describe appliances which were non-existent when previous writers produced their works. Thus we find in the present work that modern vibratory screens, such as the Hum-mer Screen, are fully described, though unfortunately the author seems to have little personal knowledge of their working and is forced to fall back upon the statements of the various makers for information as to their screening capacity.

The book is divided into three parts, the first devoted to the principles of ore dressing and containing chapters on the principles of what the author terms gravity processes of concentration, on breaking, crushing, grinding and pulverising, on volumetric sizing, on classifying, on concentration and separation, fine sand concentration, flotation and magnetic and electrostatic separation. The second part is devoted to stamp-milling and plate amalgamation, and the third part to mill accessories.

The great defect of the whole work is that the author's ideas on the subject do not yet appear to have properly clarified; as above noted, he devotes one part of his book to the stamp-milling and amalgamation of gold ores; now, it is a moot point whether this subject should be included under the head of ore dressing or not, though undoubtedly arguments can be brought forward to justify its inclusion; what is, however, not justifiable is that a writer should include it among ore-dressing processes when he commences by stating that "The actual extraction of the metals from the ore is not attempted by these processes." It is quite obvious that this definition would exclude the extraction of gold from its ores by the above methods. Again the author places log washers, thickeners and mechanically-worked classifiers among mill accessories. It never seems to have occurred to him that these are examples of what he terms gravity processes of concentration. The objection to the above phrase is that it includes two different methods of working which the author of this work has chosen to place under one head, without appearing to see the essential differences underlying them. These gravity processes of separation really include hydraulic and pneumatic separation, which ought to receive separate consideration. The author of this book has, however, practically excluded pneumatic separation except for a casual reference under jigs to the effect that "Where water is scarce, and for certain purposes, such as the removal of dust from finely ground material, the use of air under pressure in place of water is quite effective," and he illustrates this casual remark by a brief description of a pneumatic jig. The important differences between hydraulic and pneumatic separation are never touched upon, and no reference whatever is made to a number of pneumatic appliances, some of which, like the Sutton-Steele table, have attained a certain measure of importance.

It will be gathered that none of the chapters of the book can be considered as really satisfying a modern standard, but easily the worst of them all is that dealing with magnetic separation. The author appears to have no knowledge of the principles upon which this is based, and the only appliance which he mentions is an old-fashioned machine for the dry treatment of minerals of high magnetic permeability. In modern practice minerals of high permeability are practically always treated wet, and there are a number of efficient wet separators on the market; these are not even mentioned. An even worse fault is his omission to mention in any way appliances for the treatment of minerals of low magnetic permeability, of which the Wetherill magnetic separator has been the prototype. The author's ignorance of modern European practice might perhaps be excusable, but magnetic separation has made great strides and has been employed on a large scale in recent years in the United States, so that an American author ought really to know something about this portion of the subject.

The book is liberally illustrated, but many of the illustrations are too small for clearness; scales are conspicuous by their absence.

Henry Louis

LOW TEMPERATURE CARBONISATION. By C. H. LANDER and R. F. MACKAY. Pp. 277. London: E. Benn, Ltd., 1924. Price 35s. net.

Low-temperature carbonisation seems to possess a never failing interest for many, not only in scientific circles, but also of the general public. The evils of smoke from the use of raw coal are so apparent. The same coal partially carbonised would yield a smokeless fuel which would readily ignite and burn in the fireplaces now installed in British homes. Added to that there would be by-products of carbonisation which, on the analogy of the existing carbonisation industries, might be expected to yield a considerable revenue and, incidentally, contribute to the supply of liquid fuel which modern transport on sea and on land demands in ever increasing quantities. As has been truly said, the advantages are too obvious. There are, of course, snags, many of them, which hinder the development of low-temperature processes, as many of the investing public know, who have put up the necessary capital. Unfortunately, in the past, insufficient well-authenticated results have been publicly available to enable the claims put forward from time to time by interested parties to be tested, a want which this book will certainly fill. The authors have been intimately associated with the work on low-temperature carbonisation which the Fuel Research Board has made one of its principal objects. The writer is inclined to think that the production of this book is not the least valuable result of the Fuel Research staff's work. It is also a recommendation that the book under review is written round the results of the work at the Fuel Research Station—for books which are the records of first-hand experience cannot be too warmly welcomed. The fact that these results are among the few available and emanating from independent sources renders them peculiarly important.

There is a considerable space devoted to supply of fuel in general, and particularly as it affects British conditions. It is interesting to notice here that whilst low-temperature carbonisation appeals to us primarily as a source of smokeless household fuel, elsewhere it is mainly the liquid products which are sought. Free-burning domestic fuel is relatively unimportant in countries where closed stoves are almost universal.

There follow important chapters on the fundamentals of the subject—the classification of coal, the chemistry of the processes and products of coal carbonisation. To the trained chemist it may seem that unnecessary space is allotted to the formulæ and characteristics of compounds which are to be found in any standard textbook of organic chemistry. The profound difference between the effects of carbonisation at high and at low temperature has been repeatedly disclosed by the studies made from time to time in the laboratory, and these are traversed in the text.

The important subject of technical problems is treated in Chapter X, which will enable the enquiring reader to understand why low-temperature processes have made such modest headway in spite of the existence of the present gas and coke industries. These are not troubled to the same degree by the swelling of coal during the carbonisation or by the production of a coke which is too friable to stand the handling which must be incurred in distribution. Both have proved most serious problems to the early inventors of low-temperature processes, but the intensive work of recent years shows that neither can now be regarded as insurmountable. The merits of low-temperature coke as fuel are surveyed with a temperance which is commendable. In countries where winter temperatures are so low; or where fuel is so costly as to rule out the open fire as a means of domestic heating, low-temperature coke makes no special appeal. Burned in a closed stove, it has no marked advantages over gas coke or anthracite. For this reason the writer thinks that some claims for low-temperature coke, as for domestic water heating in an independent boiler, are rather overstated (p. 151).

Chapter XIII on the tar produced is largely a record of the results of the Fuel Research Station tests. These show that early expectations and claims as to the quantity and value of the tar products are without justification. Many of the constituents which give to high-temperature tar its commercial value are absent from the low temperature products, whilst other important fractions have no value to-day greater than that of crude fuel oil. It is here that the lessons of the coal-tar industry are useful. Gasworks tar was once similarly placed, and its many applications were only gradually discovered and its value was correspondingly realised. The same path will have to be followed by the newer industry. The production of ammonia as a by-product cannot be expected to help low-temperature carbonisation greatly, but the question is dealt with, and recent work bearing on the problem has been discussed.

Chapter XIX examines the no less formidable economic difficulties which will face a low-temperature industry when it has to be established on a national scale—*i.e.*, when markets have to be found for the products from millions of tons of coal. It is clear that all the products will have to find a stable market if the industry is to have a chance, and here the sale of the gas assumes a key position. The town gas industry seems to be the only one which can utilise properly the kind and quantity of gas contemplated. It is shown that the fabulous profits often imagined are not likely to be realised.

The book itself is a handsome and presentable example of the publisher's art which one is accustomed to look for from the firm which has issued it. It can be recommended to all who wish to find solid ground for opinions on so controversial a subject.

H. J. HODSMAN

The large concentrator of the Consolidated Mining and Milling Co., at Anyox, British Columbia, has begun to work on low grade copper ore. Its capacity is 1500 t. of ore a day, and it is estimated there exists, for concentration, about 8—10 million t. of ore.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

German Reparation (Dyestuffs)

In a written answer to Mr. Baker, Mr. Lunn stated that the deliveries of dyestuffs as reparation to Allied Powers from the commencement up to December 31, 1923, are as follows :—British Empire, 7,664,993 kg. ; Italy, 6,274,601 kg. ; France, 4,276,533 kg. ; Belgium, 1,219,214 kg. ; United States, 2,391,589 kg. ; Japan, 679,313 kg. ; Greece, 67,006 kg. ; and Serbia, 10,140 kg., making a total of 25,583,389 kg.—*June* 23.)

Dyestuffs

Replying to Mr. Black, Mr. Webb said that the total importation of synthetic indigo during 1923 amounted to 413 tons. No reparation dyestuffs were normally sold to the British Dyestuffs Corporation, but in 1922, with the approval of the users, a special transaction was entered into to sell to the Corporation a quantity of 333 tons of synthetic indigo dye which was requisitioned from Germany. In the absence of complete returns from the Reparation Commission the Board was unable to furnish the value in sterling. This special parcel of indigo was sold to the British Dyestuffs Corporation at cost plus freight and charges plus 5 per cent. on the gross cost. The difference between cost and selling price would be brought to account by the Board in the Reparation Dyestuffs Trading Account. With the approval of indigo users in this country the Corporation agreed to re-sell these dyes in combination with a quantity of their own products at prices not to exceed 1s. 3d. per lb. in the ease of sales to large consumers. The transaction had not been repeated.—(*June* 24.)

Vinegar

Mr. Hannon moved: "That leave be given to bring in a Bill to prevent the sale of liquids or products made in imitation of and purporting to be vinegar," as it was one of the defects of the Food and Drugs Act in this country that no provision had been made for fixing the standard of vinegar. The Bill proposed to define malt vinegar and imitation vinegar. Malt vinegar was a brewed product prepared by the alcoholic and subsequent acetous fermentation of barley or some other cereal, the starch of which had been converted by malt. Imitation vinegar was prepared from commercial acetic acid. The Bill followed principles which have been already adopted under similar legislation in the United States, New Zealand, South Africa, Australia and Canada, namely, provisions for defining what vinegar really is, provisions for labelling of vinegar so that the public will not be deceived, the fixation of penalties for the violation of the law, and arranging procedure in relation to offences under the Act. The object of the Bill was to fix a standard compelling the vendor, whether wholesale or retail, to sell to the public, as pure vinegar or malt vinegar, vinegar brewed in accordance with the principles for the making of malt vinegar. The motion was accepted. — (*June* 25.)

Drug Trade In India

Answering Mr. C. Wilson, Mr. Richards stated that the drug trade in India is regulated by the Opium Act of 1857 and 1878, the Excise Act, 1896, a number of Provincial Acts, and Rules under these Acts. The provisions of these Acts and Rules were not identical with those of the Dangerous Drugs Act, but they enabled the Government of India to fulfil her obligations under the Hague Convention. The consumption in the Punjab in 1922–23, though greater than in the previous year, was only 25,494 grains, or about one grain per thousand of the population, which is very greatly below the consumption in European countries. The consumption of opium per head was 8·5 grains in 1902—1903, and 5·25 grains in 1922—23. During the year 1912—1913 the consumption per head was 10·75 grains, but there had been a steady decline since that year. The gross revenue from licence fees and duty was 17 lakhs, 79,917 rupees in 1902—1903, and 35 lakhs, 86,027 rupees in 1922–1923.—(June 30.)

COMPANY NEWS

BLEACHERS' ASSOCIATION, LTD.

The report for the year ended March 31, 1924, shows a trading profit of £1,091,628, after deducting central charges and interest, and charging £379,328 for repairs and maintenance, estimated amounts for income tax, corporation tax and special repairs. From this sum £180,000 has been deducted for depreciation fund, £15,000 for leasehold and sundry property accounts, and £101,250 for debenture interest, leaving a net profit of £795,378, to which is added £361,712 brought forward. The final dividend proposed is 15 per cent. actual, making 20 per cent. for the year. The sum of £371,885 remains to be brought forward, after allowing for payment of the preference dividends.

COURTAULDS, LIMITED

A meeting of the shareholders will be held on July 17 to pass a resolution made by the directors in favour of a new bonus to shareholders. It has been decided to place a value of £16,013,629, instead of £7,804,021 as shown by the balance sheet on December 31 last, upon the shares held by the company in the American Viscose Corporation, and to carry the additional amount of £8,209,608 to the credit of capital reserve account. The directors have also decided to increase the capital from 12 to 20 millions by creating 8 million of 5 per cent. cumulative preference shares of £1 each, and to distribute these shares as fully paid among the shareholders at the rate of two preference shares for every three existing shares, the first dividend on the new preference shares being payable on January 1 next for the six months ended December 31. The dividends are to be paid half-yearly, less tax. This handsome gift to the shareholders indicates the great prosperity of this artificial silk manufacturing company, whose capital, since 1914, has been multiplied ten times, its profits about six times, and the

amounts appropriated to reserves seven times. The directors have also declared an interim distribution on the ordinary shares of 1s. 3d., the same amount as last year. The present ordinary dividend absorbs about £1,800,000 net and the new preference shares will take £400,000, less tax, annually. Assuming that the profits maintain the 1923 level—about £3,000,000—it would be possible to meet the interest on the new preference capital without reducing the ordinary dividend, and still leave a substantial margin for reserves.—(*The Times*, June 30.)

REPORTS

Report on the Industrial, Commercial, and Economic Situation in Poland, February, 1924. By R. E. Kimeus, Commercial Secretary, Warsaw. Department of Overseas Trade. Pp. 40. H.M. Stationery Office, 1924. Price 1s. 6d.

The country has continued to experience great financial difficulty, and in the year under review the whole life of the country was affected by the depreciation in the currency. The advent to power of M. Grabski was generally welcomed in business circles, but it is recognised that his stringent taxation programme must inevitably cause at first a general increase in prices, reduced production, and more unemployment. The conditions in industry, however, mitigated to some extent the effects of the financial collapse. The first year of Polish administration in Upper Silesia showed a considerable improvement, the collapse of the mark and the Ruhr occupation helping to produce this result.

The favourable position declined towards the end of the year, increased costs of production being largely responsible as exports necessarily fell. The textile industry felt this decline markedly in the middle of the year, but the chemical industry made satisfactory progress, and production increased. The chief raw materials imported for this industry are pyrites, phosphates, sodium nitrate, dyestuff intermediates, and fats, the last-named being the only one principally obtained from Great Britain; nearly all the necessary machinery is imported from adjacent countries. The metallurgical industry is steadily recovering from the effects of the German occupation; many imports are absorbed by this industry, steel being obtained largely from Great Britain. The output of sugar, improved, the estimated production being 320,000 t.

The favourable trade balance of recent years was maintained in 1923, exports being about 11 per cent. greater than imports. Owing to competition from Germany not being so keen imports from Great Britain were maintained throughout the year at about £278,000 per month, but for this trade to increase prices must fall. The information given in the last report (*cf. Chem. and Ind.*, 1923, 776) on the system of trading and payment that should be used by intending traders is repeated in detail. Colonial goods, chemicals, and machinery are among articles in demand from this country.

Development of the mining industry was satisfactory in 1923. The output of iron ore (Jan., to Oct.) was 366,600 t., of zinc ore, 200,600 t., of lead ore, 14,000 t., of salt, 300,327 t., and of potassium salts, 54,154 t. Coal production amounted to 30,300,374 t. in the same period. The petroleum industry showed some expansion, the output in 1923 being 632,044 t., about 114,000 t. more than in 1922.

Report on the Commerce and Industry in Bulgaria, dated February, 1924. By C. B. Peake. Department of Overseas Trade. Pp. 20. H.M. Stationery Office, 1924. Price 9d.

The favourable conditions obtaining in Bulgaria at the end of 1922 have not led to any marked improvement in the state of the country. Fluctuation in the value of the lev between 860 in February and 350 in June had an unsettling effect, and for a time exportation was impossible. The question of reparations and other obligations has affected the budget, which for the current year will show a deficit, another disturbing factor. The present year can hardly be satisfactory for trade on account of the embargo on importation, which has been placed on 150 classes of goods, and which will affect British traders seriously, though textiles may still be imported. The country is in as good a position as most Balkan States, however, and progress may be noticeable again soon. The natural resources, which are capable of development, may prove of interest to British investors in the near future.

The latest trade figures are for 1922. As foreshadowed in the last report (*cf. Chem. and Ind.*, 1923, 662) exports exceeded imports, the former being valued at 4,330 million levas, and the latter at 4038 million levas. Germany supplied 21 per cent. of the imports, Great Britain 15 per cent., and Italy 12 per cent. Of the exports Turkey took 25 per cent., Germany 17 per cent., and Italy, 13 per cent. The embargo mentioned above makes the opening up of trade difficult, but attention might usefully be given to the demand for motors and agricultural machinery, though here good credit terms must be allowed.

The country is largely agricultural, and the good cereal harvest in 1923 was of great value. The beet production was also good, and the 38,000 t. of sugar which should be obtained will suffice for home needs. Coal was mined in 1922 to the extent of 1,021,327 t. whilst salt and copper were also obtained to a small extent.

STEEL PRODUCTION IN FRANCE IN APRIL, 1924

On May 1, 136 blast furnaces were working in France, being the same number as on April 1. At the same time 39 were ready for firing, and 45 were being built or repaired. The total output of cast iron in April was 651,323 tons, an increase of 16,759 t. over March, and the production of steel rose to 567,485 t.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech.	£23 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	£45 per ton.
Powder	£47 per ton.
Acid Hydrochloric	3s. 6d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers' works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder	Spot £11 d/d.: Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Methylated Spirit 64 o.p.—	
Industrial	3s. 1d.—3s. 5d. per gallon, according to quantity.
Mineralised	4s. 2d.—4s. 6d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	5¾d. per lb.
Potass. Chlorate	3d.—4d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£3 10s. per ton d/d.
Soda Caustic, solid	Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton, carr. paid.
Sod. Bichromate	4½d. per lb.
Sod. Bisulphite Powder 60/62%	£18—£19 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £14 10s. per ton d/d.
Sod. Sulphide cryst.	£9 per ton d/d.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	5¾d.—1s. 4d. per lb., according to quality.
Crimson	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 11d. per lb.
Barytes	£3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide	3s. 9d. per lb.
Carbon Bisulphide	£24—£26 per ton according to quantity.
Carbon Black	6¼d.—6¾d. per lb. Market firmer.
Carbon Tetrachloride	£56 per ton, drums free.
Chromium Oxide, green	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	45s per cwt., barrels free.
Lead Hyposulphite	7½d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£15 10s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Sulphur Chloride	3d. per lb., carboys extra.
Thiocarbanilide	2s. 6d. per lb.
Vermilion, pale or deep	4s. 10d. per lb.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£14 10s. per ton d/d. Demand active.
Grey	£19—£20 per ton. Fair demand.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 per ton, according to grade and locality. Demand below normal.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. „ „ 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 7d. per gall. Unrefined.
Wood Naphtha—	
Miscible	5s. per gall. 60% O.P. Market dull.
Solvent	5s. 6d. per gall. 40% O.P. Fairly good demand.
Wood Tar	£5 per ton.
Brown Sugar of Lead	£46 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	6½d.—6¾d. per lb. Better inquiry.
Crude 60's	1s. 9d.—1s. 10d. per gall. Market flat. Only odd lots being offered.
Acid Cresylic, 97/99	2s 1d.—2s. 2d. per gall. Demand still good. Market firm.
Pale 95%	1s. 10d.—1s. 11d. per gall. Steady demand.
Dark	1s. 8d.—1s. 11d. per gall. Steady business.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	9½d. per gall. Very quiet.
Unstrained	8½d.—9d. per gall.
Benzole—	
Crude 65's	10½d.—1s. per gall. ex works in tank wagons.
Standard Motor	1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure	1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.
Toluole—90%	1s. 5½d. per gall.
Pure	1s. 10d.—2s. per gall.
Xylol coml.	2s. 3d. per gall.
Pure	3s. 3d. per gall.

Creosote—	
Cresylic 20/24% ..	9d.—9½d. per gall. Few inquiries.
Middle Oil ..	6½d.—9d. per gall. according to grade and district. Market very quiet.
Heavy	
Standard Specification	
Naphtha—	
Solvent 90/160 ..	1s. 4d.—1s. 5d. Market steady.
Solvent 90/190 ..	1s. 1d.—1s. 4d. Fair business passing.
Naphthalene Crude—	
Drained Creosote Salts	£6—£6 10s. Demand falling off.
Whizzed or hot pressed	£9—£12 per ton. Little business.
Naphthalene—	
Crystals and Flaked ..	£16—£17 per ton.
Pitch, medium soft ..	52s. 6d.—57s. 6d. per ton. No export business at present. Plenty of inquiries for next season.
Pyridine—90/160 ..	21s.—22s. per gall. Market less firm.
Heavy ..	12s.—12s. 6d. Market steady.

INTERMEDIATES AND DYES

Business in dyestuffs has been fairly good, but very little improvement is shown. Prices remain constant.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% ..	1s. 6d. per lb.
Acid H	4s. 3d. per lb 100% basis d/d.
Acid Naphthionic ..	2s. 4d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech. ..	1s. 1½d. per lb. Steady demand.
Acid Sulphanilic ..	9½d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	7¾d.—8½d. per lb. naked at works.
Aniline Salts	7¾d.—9d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95% ..	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 19/31° C. ..	4½d. per lb. Demand steady.
m-Cresol 98/100% ..	2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C. ..	2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline	3s. per lb.
Dichloraniline S. Acid ..	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£75 per ton.
Diethylaniline	4s 9d. per lb. d/d., packages extra, returnable.
Dimethylaniline	2s. 4d. per lb. d/d. Drums extra.
Dinitrobenzene	9d. per lb. naked at works.
Dinitrochlorbenzol ..	£84 10s. per ton d/d.
Dinitrotoluene—48/50° C.	8d.—9d. per lb. naked at works.
66/68° C.	1s. 2d. per lb. naked at works.
Diphenylamine	3s. per lb. d/d
Monochlorbenzol ..	£63 per ton.
β Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine ..	1s. 4½d. per lb. d/d.
β-Naphthylamine ..	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 4d. per lb. d/d.
Nitrobenzene	5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol ..	2s. per lb. 100% basis d/d.
Nitronaphthalene ..	11¾d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-o-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine ..	4s. 2d. per lb. d/d.
p-Phenylene Diamine ..	10s. 3d. per lb. 100% basis d/d.
R. Salt	2s. 6d. per lb. 100% basis d/d.
Sodium Naphthionate ..	2s. 5d. per lb. 100% basis d/d.
o-Toluidine	8½d. per lb.
p-Toluidine	3s. 6d. per lb. naked at works.
m-Toluylene Diamine ..	4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P ..	£47 per ton.
Acid, Acetyl Salicylic ..	3s. 3d. per lb. Value and demand maintained.
Acid, Benzoic B.P. ..	3s. 6d. per lb. Larger supplies available. Market easier.
Acid, Boric B.P. ..	Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain. Prices reduced by £3 per ton.
Acid, Camphoric.. ..	19s.—21s. per lb.
Acid, Citric	1s. 6½d. per lb., less 5% for ton lots. Market extremely firm. Upward tendency.
Acid, Gallic	3s. per lb. for pure crystal. Market firmer.
Acid, Pyrogallic, Cryst. ..	7s. per lb. for 1 cwt. lots. Market firm; increasing demand.
Acid, Salicylic	Prices quoted from 2s. per lb. down to 1s. 7d. for ton lots. Market still weak. Keen competition and smaller demand.
Acid, Tannic B.P. ..	3s. per lb. Market quiet.
Acid, Tartaric	1s. 1½d.—1s. 2d. per lb. less 5%. Better tone but not yet very active. Cheap offers of second hand parcels of foreign acid. Higher prices expected in view of firmness of raw materials.
Amidol	9s. per lb. d/d.
Acetanilide	2s. 3d. per lb. for quantity. Demand slow. Prices shaded to secure large orders.
Amidopyrin	13s. 3d. per lb. Neglected. Stocks low.
Ammon. Benzoate ..	3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate ..	12s. 6d. per oz. for English make.
Barbitone..	15s. per lb. Quiet market.
Benzonaphthol	6s. per lb. Small inquiry.
Bismuth Salts	A steady market. Prices according to quantity:
Bismuth Carbonate ..	12s. 9d.—14s. 9d. per lb.
„ Citrate.. ..	11s. 4d.—13s. 4d. „
„ Salicylate ..	10s. 2d.—12s. 2d. „
„ Subnitrate ..	10s. 9d.—12s. 9d. „
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides—	Fluctuating market. Continental prices decidedly firmer.
Potassium	11d. per lb.
Sodium..	1s. „
Ammonium	1s. 1d. per lb.
Calcium Lactate.. ..	Demand active. Good English make can be had from 1s. 7d to 2s. 6d. per lb.
Chloral Hydrate ..	3s 7d.—3s. 9d. per lb, duty paid
Chloroform	2s. per lb. for cwt. lots. Very steady
Creosote Carbonate ..	6s. 0d. per lb. Little demand.
Formaldehyde	£55 per ton, *ex* works. English make.
Glycerophosphates—	Fair business passing.
Calcium, soluble and citrate free	7s. per lb.
Iron	8s. 9d. per lb.
Magnesium	9s. per lb.
Potassium, 50% ..	3s. 6d. per lb.
Sodium, 50%	2s. 6d. „

Guaiacol Carbonate	11s. per lb. for cwt. lots. Slightly cheaper.
Hexamine	3s. 6d. per lb. for English make. Market quiet and steady.
Homatropine Hydrobromide	30s. per oz.
Hydrastine hydrochlor	English make offered at 120s. per oz.
Hydroquinone	4s. 3d. per lb. in cwt. lots. Foreign make.
Hypophosphites—	
Calcium	3s. 6d. per lb., for 28-lb. lots.
Potassium	4s. 1d. per lb.
Sodium	4s. ,,
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 5d. per lb., according to quantity.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£75 per ton, less 2½%.
Heavy Commercial	£26 per ton, less 2½%.
Heavy Pure	2s.—2s. 2d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	52s. 6d. per lb. Weaker.
Synthetic	26s.—35s. per lb., according to quantity. English make. Steady demand.
Mercurials	Market firm.
Red oxide	5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	3s. 6d.—3s. 7d. ,,
White precip.	4s. 7d.—4s. 8d. ,,
Calomel	3s. 11d.—4s. ,,
Methyl Salicylate	2s.—2s. 3d. per lb. for carboys. Not much demand.
Methyl Sulphonal	20s. per lb.
Metol	11s. per lb. British make.
Paraformaldehyde	3s. per lb. More inquiry.
Paraldehyde	1s. 4d.—1s. 6d. per lb. in free bottles and cases, according to holder and quantity.
Phenacetin	6s. per lb. Ample stocks available.
Phenazone	7s. 3d. per lb. for cwt. lots. Quiet.
Phenolphthalein	6s. 6d. per lb. Easier with supplies more plentiful.
Potass. Bitartrate—	
99/100% (Cream of Tartar)	88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate	1s. 10d.—2s. 2d. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Metabisulphite	7½d. per lb., 1-cwt. kegs included.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	5s. 6d. per lb. Sales slow.
Saccharin	63s. per lb., in 50-lb. lots.
Salol	3s. 6d.—3s. 11d per lb. Easier in sympathy with other salicylates.
Silver proteinate	9s. 6d. per lb.
Sod. Benzoate, B.P.	2s. 9d. per lb. In quantity for British product.
Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity. Firm in common with other citrates.
Sod. Hyposulphite—	
Photographic	£13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	77s. 6d.—81s. 6d. per cwt., according to quantity. Market quiet.
Sod. Salicylate	Market more active. Powder 2s. 2d.—2s. 6d. per lb. Crystal at 2s. 5d.—2s. 8d. per lb. Flake 2s. 9d.—2s. 10d. per lb.
Sod. Sulphide—	
Pure recryst.	10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Thymol	15s. 9d.—17s. 6d. per lb. for good white crystal from ajowan seed. Very firm and scarce.

PERFUMERY CHEMICALS

Acetophenone	12s. 6d. per lb.
Aubepine	14s. 6d. ,,
Amyl Acetate	2s. 9d. ,,
Amyl Butyrate	6s. 9d. ,,
Amyl Salicylate	3s. 3d. ,,
Anethol (M.P. 21/22° C.)	4s. 6d. ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 10½d. ,,
Benzyl Alcohol free from Chlorine	2s. 10½d. ,,
Benzaldehyde free from Chlorine	3s. 6d. ,,
Benzyl Benzoate	3s. 6d. ,,
Cinnamic Aldehyde Natural	15s. 6d. ,,
Coumarin	20s. ,,
Citronellol	16s. ,,
Citral	10s. ,,
Ethyl Cinnamate	15s. ,,
Ethyl Phthalate	3s. 3d. ,,
Eugenol	10s. 6d. ,,
Geraniol (Palmarosa)	35s. ,,
Geraniol	11s.—18s. 6d. per lb.
Heliotropine	7s. per lb.
Iso Eugenol	15s. 9d. ,,
Linalol ex Bois de Rose	26s. ,,
Linalyl Acetate	26s. ,,
Methyl Anthranilate	9s. 6d. ,,
Methyl Benzoate	6s. ,,
Musk Ambrette	45s. ,,
Musk Xylol	16s. 6d. ,,
Nerolin	4s. 9d. ,,
Phenyl Ethyl Acetate	12s. 6d. ,,
Phenyl Ethyl Alcohol	16s. ,,
Rhodinol	57s. 6d. ,,
Safrol	1s. 10d. ,,
Terpineol	2s. 4d. ,,
Vanillin	24s.—24s. 9d. per lb. Price reduced. Demand steady.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	15s. 6d. per lb.
Anise Oil	2s. 8d. per lb.
Bergamot Oil	19s. 6d. per lb.
Bourbon Geranium Oil	36s. 6d. ,,
Camphor Oil	75s. per cwt.
Cananga Oil Java	10s. 6d. per lb.
Cinnamon Oil, Leaf	6½d. per oz.
Cassia Oil, 80/85%	8s. 9d. per lb.
Citronella Oil—	
Java 85/90%	6s. per lb.
Ceylon	3s. 9d. per lb.
Clove Oil	7s. 3d. per lb.

Eucalyptus Oil 70/75% ..	2s. 2d. per lb.
Lavender Oil—	
French 38/40% Esters	27s. 6d. per lb.
Lemon Oil	3s. 2d. per lb.
Lemongrass Oil ..	3d. per oz.
Orange Oil, Sweet ..	13s. 9d. per lb.
Otto of Rose Oil—	
Bulgarian	27s. 6d. per oz.
Anatolian	23s. 6d. per oz.
Palma Rosa Oil	19s. per lb.
Peppermint Oil—	
Wayne County ..	20s. 9d. per lb.
Japanese	15s. 6d. per lb.
Petitgrain Oil	10s. per lb.
Sandal Wood Oil—	
Mysore	26s. 6d. per lb.
Australian	21s. per lb.

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before August 25; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on July 10th.

I.—Applications

Douglas. Apparatus for separating liquids from granulated substances. 14,827. June 19.

Green and Ogden. Separating chemically-inmiscible liquids. 14,894. June 19.

Holloway and North British Diesel Engine Works. Centrifugal separators. 14,693. June 18.

Nyrop. Method of altering properties of fluids. 14,627. June 17.

Ritchie. Drier. 14,561. June 16.

Schindler. Mixing drums. 15,041. June 21. (Switz., 27.6.23.)

Wade (Duff Patents Co.). Furnaces. 14,573. June 16.

Weiss. Drying-cylinders etc. 14,881. June 19.

I.—Complete Specifications Accepted

3116 (1923). Lilleshall Co., Ltd., and Bishop. Centrifugal filter or separator. (217,264.)

16,691 (1923). Heyl. *See* II.

20,299 (1923). Brackett, and Brackett and Co., Ltd. Screening or filtering apparatus. (217,462.)

21,137 (1923). Elmore (Comley). Removal of free moisture from substances by centrifugal means. (217,469.)

22,640 (1923). Duclaux. Manufacture of ultra-filter membranes. (203,714.)

5552 (1924). Grauss. Centrifugal drying-machines. (212,551.)

II.—Applications

Forst. 14,777. *See* VII.

Frey. Fuel compact. 14,753. June 18. (U.S., 25.7.23.)

Glasgow, and Humphreys and Glasgow, Ltd. Water-gas generators. 14,714. June 18.

Hey. 14,540, 14,945. *See* XII.

Heyl. Obtaining volatile products from mineral deposits *in situ*. 14,541. June 16.

Heyl. Treatment of sulphur-containing oils. 14,924. June 20.

Hines. Laying dust in coal mines etc. 14,587. June 17.

Mailhe. Production of petroleum from vegetable etc. oils and glycerides. 14,743. June 18. (Fr., 28.6.23.)

Moore. Manufacture of combustible gases. 14,798. June 19.

Rude. Production of water gas from solid fuel. 14,708. June 18.

II.—Complete Specifications Accepted

9023 (1923). Corthesy and Mills. Combustion of fuel. (217,359.)

10,247 (1923). Thornton and Illingworth. *See* VIII.

16,691 (1923). Heyl. Rotary distillation retorts. (217,428.)

1653 (1924). Koppers Co. Regeneratively-heated vertical retort furnaces. (210,085.)

III.—Complete Specification Accepted

18,691 (1923). Baglin. Regenerative coke ovens. (217,454.)

IV.—Applications

Forcart, and Haco Ges. Production of albumen-dyestuff products etc. 15,031. June 21.

Imray (Soc. of Chemical Industry in Basle). Manufacture of dyestuffs. 14,768. June 18.

IV.—Complete Specification Accepted

2377 (1924). Chemische Fabrik Griesheim-Elektron. *See* VI.

V.—Application

Courtaulds, Ltd., and Gardner. Manufacture of threads or filaments of cellulose esters. 14,943. June 20.

V.—Complete Specifications Accepted

6570 (1923). Dreyfus. Manufacture of threads and filaments from cellulose derivatives. (217,287.)

6986 (1923). Fine Cotton Spinners' and Doublers' Association, Ltd., Balls, and Hutchins. Preparation of fibrous materials for spinning.

20,321 (1923). Fues. Manufacture of paper. (202,314.)

VI.—Applications

Baddiley, Hill, and British Dyestuffs Corporation. Production of greenish-yellow shades on acetyl silk. 14,956. June 20.

Lepine. Dyeing etc. machines. 14,822. June 19.

VI.—Complete Specification Accepted

2377 (1924). Chemische Fabrik Griesheim-Elektron. Process of producing on the fibre azo-dyestuffs from arylamides of 2 : 3-oxynaphthoic acid. (210,462.)

VII.—Applications

Cowles. Process for producing and utilising alkalis and alumina. 14,763. June 18.

Forst. Recovery of ammonia and ammonium compounds from gases. 14,777. June 18.

Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Process for production of catalysts for synthesis of ammonia. 15,045. June 21. (Norway, 14.7.23.)

VII.—Complete Specifications Accepted

5849 (1923). Bone. Production of activated nitrogen (217,277.)

21,072 (1923). Johnson (Badische Anilin und Soda Fabrik). Manufacture of formic acid. (217,467.)

21,089 (1923). Wallace. Recovery of soda from its solutions. (217,468.)

VIII.—Application

General Electric Co., Ltd. Readily fusible glasses and enamels. 14,532. June 16. (Ger., 24.1.24.)

VIII.—Complete Specification Accepted

10,247 (1923). Thornton and Illingworth. Silica or refractory fireclay blocks and bricks for coke oven walls, furnace linings, and the like. (217,377.)

IX.—Applications

Graham and Mackay. Waterproofing concrete etc. 14,838. June 19.

Grieve, and Jameson and Co. Manufacture of emulsions of bitumen etc. 14,510. June 16.

Kaiser-Wilhelm-Institut für Eisenforschung, and Hessel. Production of artificial stone etc. 14,628. June 17. (Ger., 25.6.23.)

IX.—Complete Specifications Accepted

33,343 (1922). Holzveredelung Ges., and Trenkler. Process for hardening wood. (217,095.)

6315 (1923). Lefeburo. Concrete, cements, plasters, and the like. (217,279.)

8019 (1923). Amies. Cementitious composition. (217,343.)

11,801 (1923). Pickstone. Manufacture of mortar, artificial stone, concrete, and the like. (217,388.)

X.—Applications

Compagnie des Forges de Chatillon, Commentry, et Neuves-Maisons. Thermic treatment of steel etc. 14,976. June 20. (Fr., 13.2.23.)

Ferranti, Ltd., and Ferranti. Protection of metals. 14,869. June 19.

Fitzgerald. Means for recovering gold etc. from dilute solutions. 15,042. June 21.

Jordan. Softening aluminium-plated iron articles. 14,969. June 20.

Jordan. Aluminium plating of spooled metal bands etc. 14,970. June 20.

Kelly. After-treatment, finishing, and working of alloys etc. 14,590. June 17.

Kelly. Alloys. 14,594. June 17.

Krupp Akt.-Ges. Friedrich-Alfred-Hutte. Devices for manufacturing steel. 14,937. June 20. (Ger., 8.7.23.)

Poole. Solder. 14,897. June 20.

Soc. d'Electro-Chimie, d'Electro-Métallurgie, et des Aciéries Electriques d'Ugine. Extracting tin from minerals, alloys, etc. 14,562. June 16. (Fr., 21.6.23.)

Summers. Coating metals with other metals. 14,593. June 17.

X.—Complete Specifications Accepted

1140 (1923). Berlin. Reducing metallic oxides. (193,057.)

7408 (1923). Dicker. (N. V. Hollandsche Tungsten-draadfabriek). Treatment of tungsten and other metals having a high melting point. (217,322.)

10,165 (1923). Hooper. Production of aluminium and silicon from bauxite etc. (217,376.)

12,473 (1923). Harris. Refining of metals. (217,391.)

22,570 (1923). Geschwind. Roasting-furnaces. (217,477.)

22,746 (1923). Gelsenkirchener Bergwerks-A.-G., and Opderbeck. Granulating slag (204,318.)

XI.—Applications

Antonoff. Electric batteries. 15,040. June 21.

Bannister. Storage batteries. 14,570. June 16.

Fitzpatrick (Meyer-Keller et Cie.). 14,709. *See* XIX.

Monson Electrical treatment of solids and liquids. 14,509. June 16.

XI.—Complete Specifications Accepted

33,025 (1922). Prior and Riley. Selenium cells. (216,942.)

14,045 (1923). Jackson (Mathieson Alkali Works, Inc.). Electrolytic processes. (217,414.)

20,594 (1923). Katsumori. Electric batteries. (217,465.)

XII.—Applications

Hauschka. Manufacture of synthetic linolin. 14,480. June 16.

Hey Removal of suspended matters from oils etc. 14,510, 14,945. June 16 and 20.

Mailhe. 14,743. *See* II.

Schetelde. Manufacture of soap. 14,669. June 17.

XII.—Complete Specification Accepted

9337 (1923). Pearson and Co., Ltd., and Clark. Removing odour and flavour from cod liver oils etc., or from the unsaponifiable portion thereof in such a manner as to retain vitamin activity. (217,363.)

XIII.—Applications

Terwilliger. Synthetic resins. 14,652, 14,653. June 17. (U.S., 29.6.23 and 5.7.23.)

XIII.—Complete Specification Accepted

7434 (1923). Tyrer. Manufacture of a white pigment. (217,323.)

XIV.—Complete Specifications Accepted

22,910 (1923). Ricard, Allenet, et Cie. Vulcanisation of india-rubber. (204,052.)

3574 (1924). K. D. P., Ltd. Manufacture of caoutchouc. (213,886.)

XV.—Application

Marks (Internationale Galalith-Ges. Hoff und Co.). Manufacture of transparent artificial horn. 14,873. June 19.

XV.—Complete Specification Accepted

7129 (1923). Melamid. Tanning and the manufacture of tanning-substances. (194,723.)

XVI.—Application

Potts (Asahi Glass Co.). Manures. 14,803. June 19.

XVII.—Complete Specification Accepted

8277 (1923). Martin. Manufacture of beer, vinegar glucose, dextrin-maltose, spirits, and the like. (217,348.)

XVIII.—Application

Gaux and Salmon. Manufacture of yeasts. 14,751. June 18. (Fr., 19.6.23.)

XVIII.—Complete Specifications Accepted

8277 (1923). Martin. *See* XVII.

9012 (1923). Pollak. Production of yeast. (195,963.)

XIX.—Applications

Fitzpatrick (Meyer-Keller et Cie.). Rendering vegetable etc. materials durable by electricity. 14,709. June 18.

Hocking. Apparatus for purifying water containing grease or oil. 14,806. June 19.

Nielsen. Sterilising milk etc. 14,617. June 17.

Perky. Food product. 14,548. June 16.

Wallis. Production and use of antiseptics etc. 14,964. June 20.

XIX.—Complete Specifications Accepted

6368 (1923). Imray (Kellogg Co.). Production of food products. (217,282.)

21,916 (1923). Pico. Destructive fermentation of organic residues. (203,336.)

XX.—Applications

Kjaer. Obtaining extracts from animal organs. 14,980. June 20.

Schindelmeiser. Production of thymol and its isomers and homologues. 15,033. June 21.

XX.—Complete Specification Accepted

26,164 (1923). Soc. des Produits Azotés. Isolation of urea. (206,489.)

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35 Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number:—*Australia*: Leather goods (725); hardware (726); *Canada*: Centrifugal sewage and sludge pumps (tender) (A.X. 1081 and 1082); *Chile*: Raw products (oils etc.) for soap manufacturers (753), photographic materials (B.X. 1017); *France*: Sulphate of copper (734), tinplate, sheet iron and machines for bleaching and dyeing (735); *Italy*, raw materials for paper mills and paper (737), machine tools and technical articles (739), machinery for manufacture of artificial

silk and confectionery (740), chemicals for textile industry (742), paints (B.X./1040); *Netherlands*: Crockery (745); *Rumania*: Coconut fibre yarn (749).

French Company News

In 1923 the Cie. des Mines de Crespin Nord produced 189,406 tons of coke, 2145 t. of ammonium sulphate, 4022 t. of tar, and 16,149,540 cb. m. of gas. In the same year the Cie. des Mines de Vandin les Béthune produced 165,649 t. of coal against 140,723 t. in 1922.

The Société des Phosphates Tunisians produced 424,075 t. of phosphates in 1923, compared with 378,367 t. in 1922. The company's report states that experiments have shown that Tunisian phosphates when finely ground, can be applied directly to acid soils, an observation which confirms experiments carried out by G. Claude in Morocco, and his industrial process for grinding natural phosphates to pass a very fine mesh.

Exports of chemicals in 1924

The United States exports of chemicals and allied products during the first quarter of 1924 had an aggregate value of $32,580,385, which was 4 per cent. below the corresponding period of 1923, but 10 per cent. above the first quarter of 1922. During the three months to March, 1924, sales were the smallest. The exports of essential oils showed the largest expansion of any group of chemicals and allied products exported during the first quarter of 1924 75 per cent. in value—followed by crude drugs, with an advance of 47 per cent.: coal-tar products, 14 per cent.; and pigments, paints and varnishes, 11 per cent. In contrast to these gains, naval stores, gums, and resins decreased 26 per cent.; industrial chemicals, 8 per cent.; and perfumery etc. 4 per cent.; whilst explosives, which dropped 9 per cent. in value, rose 2 per cent. in quantity, and fertilisers and fertiliser materials fell 4 per cent. in value, but rose 11 per cent. in quantity. Coal-tar exports rose to a total valuation of $3,137,383 in the first quarter of the year, and foreign demand increased until $1,421,372 worth of crudes, $95,758 worth of intermediates, and $1,620,253 worth of finished coal-tar products were shipped abroad. A decline of 8 per cent. was registered in the exports of industrial chemicals, their value having reached $6,396,052. Total exports of mineral-earth pigments amounted to 7,455,180 lb. valued at $215,509, and outgoing consignments equalled 6,972,487 lb. worth $600,618, in the first three months of 1924. A 13 per cent. expansion was made in foreign sales of varnishes, the most important improvement for goods of this kind being in carbon and lamp-blacks, which rose from $709,640 to $1,217,922 in 1924. Fertilisers gained in quantity to the extent of 11 per cent., but lost in value by 4 per cent., sales falling from $4,329,862 in the first quarter of 1923 to $4,139,593 in the corresponding period in 1924. Explosives likewise advanced in quantities shipped, but dropped in value, and no great change was reported in dynamite. The heavy shipments of peppermint oil during the first quarter of the current year, when more than double the quantity was exported, accounted fo the big increase in essential oils. Demand fo American crude drugs swelled 47 per cent. durin the period under review, whilst medicinal and pharma ceutical preparations retained the position held i 1923. During the month of March, the shipment of antitoxins, serums and vaccines were unusuall large. After the large amounts of naval stores gums, and resins shipped abroad throughout 1923 it is not surprising that the figures for the first quarte of 1924 should fail to reach the figure for the corre sponding period of 1923. Foreign sales dropped 2 per cent., the exports of rosin decreased 18 pe cent., while spirits of turpentine fell 42 per cent On the other hand, wood turpentine, turpentin substitutes and wood tar and pitch advanced durin the 1924 period to $104,423 (125,017 gallons) $72,461 (225,300 gallons), and $73,823 (13,42 barrels) respectively.—(*U.S. Com. Rep.*, May 5 1924.)

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council of Pure and Applied Chemistry

which consists of Representatives from

The Chemical Society, the Society of Chemical Industry, the Association of British Chemical Manufacturers, the Institute of Chemistry, the Society of Public Analysts, the Faraday Society, the Institute of Brewing, the Society of Dyers and Colourists, the Society of Glass Technology, the Iron and Steel Institute, the Ceramic Society, the Institution of Gas Engineers, the Society of Leather Trade Chemists, the Royal Photographic Society, the Mineralogical Society, the Biochemical Society, the Institute of Metals, and the Royal Agricultural Society.

VOL. 43 NEW SERIES | LONDON, JULY 11, 1924 | NO. 28

EDITORIAL

We do not recollect a Presidential Address which has been more scientific than that which is printed in this week's Transactions. Presidents are apt to have a knowledge so profound that but little of it comes to the surface and their public addresses for this reason deal with generalities, the importance of chemistry to the Nation or some such topic, needing rather a facile pen and a vivid imagination than an exact knowledge of facts. Dr. Armstrong has given us a considerable mass of facts, some familiar, some which require prolonged search to obtain, but in this memoir they are conveniently arranged and their interest and importance are clearly indicated. Fats have often been considered from the point of view of those who regard them as raw materials; the conspicuous feature of this particular address is their consideration as parts of living plants and animals, how chemistry throws light on the processes by which they are built up, how they may be taken to pieces again and what function they have in the growth and life of the organism. Only the acquisitive will learn by heart the table of percentage composition of fatty acids from fats but we suppose that every one, chemist or not, with an average amount of curiosity will find pleasure in reading about the variations in the proportion of saturated and unsaturated acids, the predominance of the acids containing 10, 12, and 14 carbon atoms over all others and the probable relation of the fatty acids to starch and glucose. The chemistry of plant life has been advanced in many ways at Liverpool this address also is an important contribution to the chemistry of life. Slowly we are learning many of the secrets of Nature; it is essential to know the details of the processes before we can imitate them. Dr. Armstrong and his colleague Mr. Allen have opened a window in chemistry illuminating many an obscure point. We wish they would put before the world an equally intelligible statement of the chemistry of plant life in general. Those who are on familiar terms with fats, glucosides, sugars and enzymes have an opportunity which we trust will attract them. It should be no matter of surprise that spectroscopists in Liverpool and soap manufacturers in Warrington should be engaged on the same problem; the problem may be approached from many directions; the X-ray analysts, the stereochemists, the biochemists, all can make their contribution, not all so well as those whose achievement we are now alluding to, but every variety of physical and chemical knowledge will be required before the botanist and the zoologist can understand that life with which they are concerned. Life is mysterious, but how much of the mystery is due to our slender knowledge, we cannot say. Dr. Armstrong has done no small service in opening this window in chemistry, so that he who runs may read.

* * *

There were two papers read at Copenhagen of considerable interest, the first by Professor Biilmann on the use of quinhydrone for the rapid deter-

mination of hydrogen-ion concentration; the author also showed the apparatus, which is simple, and explained the method of using it, which appears to be easy and accurate. The other paper was by Professor Bronsted on the definition of acids and bases. If an acid be defined as a compound capable of yielding a hydrogen ion, then in addition to the easily recognised acids, such compounds as water, the ammonium ion and so on are really acids and the proper definition of a base is the substance left after an acid has lost a hydrogen ion:- hydroxyl ions, ammonia, chlorine and some other substances are thus bases; lime, litharge and caustic soda are not bases. By adopting these definitions and making use of them logically a number of interesting—and even surprising—results are obtained. The pursuit of this branch of chemistry is simple and involves no costly apparatus; whether it will have important industrial applications is not yet apparent. Many branches of human knowledge have passed through a similar logical phase, psychology, jurisprudence, religion, metaphysics and so on. In the majority of cases no permanent ill-effects have been noticed; definitions are very convenient tools but usually they are only rough approximations to the actual facts and, except in mathematics, they require continual adjustment to meet the growth of scientific knowledge.

* * *

Many of our readers must have noticed the drawings which have appeared from time to time in the illustrated papers purporting to depict the manner in which obelisks were quarried and erected in Ancient Egypt. Amazing as the performance may seem when viewed through the mists of time, it was in reality quite simple: a system of levers, a shifting fulcrum and an absence of the eight-hour day, and it was done. Yet one can imagine the chorus of "wonderful" going up in suburban homes, when the illustrations are handed round the breakfast table, though an escape of gas, a short interruption in the supply of electricity, a failure of the morning saline mixture to effervesce are hailed bitterly as signs of the degeneracy of the age. It is a pity that antiquities have so much greater an attraction for the public than evaporators or carbonisation, or that the results of the laborious investigations which led to an explanation of the action of acids on carbonates are accepted without wonder. We have the greatest interest in archaeology and have even dabbled in it ourselves, but we are concerned with chemistry and its appreciation by the non-technical man, and although this appreciation is growing satisfactorily, we shall continue to ask for more. The World Power Conference at Wembley will, from one point of view, carry out useful propaganda, for the mark of the chemist is all over it, as can be gathered on reading the account of the meeting during the first week, which has been contributed to this issue by our special correspondent. Our correspondent feels relieved that we have no commercial sources of volcanic steam in this country. However, Prince Ginori Conti's account of his work since 1904 on the utilisation of the natural steam at Lardarello in Tuscany, reminded us of the article on this subject which we published some time ago, and we were sorry that we could not see the kinematograph demonstration depicting the "soffioni," the turbo-alternators, the concentrating tanks for borax, and all the extensive plant which has grown up under his supervision. Prince Conti is an honorary member of this Society and his pioneer work is well known in this country. Those who met Prince Conti at the Annual Meeting at Cambridge last year will hope that he will be able to be present at Liverpool. Another aspect of the production and utilisation of power is presented in the paper on "Fuel Economy Questions" by Mr. Womersley, who deals more particularly with the boiler plant and makes interesting suggestions that merit the attention of steam users. We cannot avoid the subject of power and it is only owing to the admirable organisation of the chemical industry that labour, although costly, does not provide us with still more difficult problems to solve. And we hope that those who are enjoying the meeting at Liverpool will remember the devoted labour of those who for a long period have worked so tirelessly, so strenuously, to perfect its organisation, and will express their appreciation of the local Committee's arduous work by more than a formal vote of thanks.

* * *

The paper on "Soil Problems and Soil Population," by Mr. Gimingham, is a handy resumé of much recent work. Every amateur gardener knows that the soil population is considerable, but it is only those who pursue their investigations in a scientific manner who can appreciate the vast numbers of microscopic beings which inhabit the soil. We appeal to some of these for advice of a practical kind. A gardener of our acquaintance has a greenhouse infested by wood-lice; according to his account they are as "innumerable as the stars of night, or stars of morning, dewdrops, which the sun impearls on every leaf and every flower." He has read a number of treatises on hydrogen-ion concentration, and watered the ground with many strange devices. Nevertheless, every time the good, easy man thinks his greatness full surely is a ripening, the little brutes come and devour the tenderest rootlets of the most precious specimens, finally killing them. On our advice he watered the soil with an aqueous solution, we think that is the phrase, of creosote. From every cranny and hole there emerged great brown wood-lice, little pink ones, innocent sucklings, fathers, mothers, uncles, cousins, cocking tails and pricking whiskers, families by tens and dozens, brothers, sisters, husbands, wives. For the moment they are running and crawling to a greener, cleaner land, but in a day or two they will return to their old haunts, their old pastures, like a flock of locusts. Is there no soil medicine, no Mothersill, no Yadil, which will make the soil healthy and strong again? Will lime, or litharge, quinhydrone or tartaric acid avail? What Fourneau, what Morgan, what Thorpe or Ingold will come to our friend's assistance? Can he cut of supplies of boron, magnesium or vitamins? We trust we do not appeal in vain.

SOCIETY OF CHEMICAL INDUSTRY

THE ANNUAL GENERAL MEETING, JULY 9, 1924.

The Annual Meeting of the Society of Chemical Industry in Liverpool has been honoured by the patronage of His Majesty the King. This is the second occasion on which His Majesty has thus signified his appreciation of the work of the Society, and the Society will no doubt make strenuous efforts to deserve such encouragement in the future and by deserving it to obtain it.

The meeting has been organised by a General Committee consisting of the Liverpool Section Committee assisted by the Lord Mayor of Liverpool, Mr. Arnold Rushton, Sir Max Muspratt, Bart., Mr. Roscoe Brunner and several others well known in Liverpool and in chemical circles. It may be presumed that the bulk of the work has been done by the Chairman of the Section, Mr. Edwin Thompson and by the Hon. Secretary, Mr. E. Gabriel Jones, and only those who have taken part in the organisation of such a meeting can realise the volume of the work involved, the minute attention to detail required and the many long hours spent by the committee in making the necessary preparations for a successful gathering which includes both social and scientific functions. There will be receptions, dinners, luncheons, visits to the works of Messrs. Joseph Crosfield & Sons, Ltd., and of The United Alkali Co., Ltd., a dance, and an important contribution to our knowledge of fats delivered by our President in conjunction with Mr. John Allan. About four hundred members and guests have signified their intention to be present. Among the distinguished foreigners who are expected are: the President of the Dutch Chemical Society, Dr. C. J. Van Niewenburg, Prince Ginori Conti, an Honorary Member of the Society of Chemical Industry, whilst Dr. A. C. Fieldner represents the American Chemical Society and Dr. Bjarne Johnsen represents the American Section of the Society of Chemical Industry. Monsieur Paul Kestner, the President of the Société de Chimie Industrielle, is prevented by indisposition from attending the meeting. All will regret his absence and hope that he will soon be in much better health. Several years of devotion to the interests of his country, his science and the industry with which he is connected compel him to take a much needed rest.

Dr. Armstrong now retires from the Presidential Chair which he has occupied during the last two years. He signalises his retirement not merely by bowing politely but by providing an interesting account of the chemistry of fats as the result of many years work by himself, Mr John Allan and some other colleagues. This address will be found in the Transactions of the Society, and even those who make no pretence to intellectual eminence or scholarship sublime can enjoy reading it and will find many passages in it which will excite their curiosity and attention. During his Presidency this weekly journal was launched; the Society's Journal has gradually grown in volume, has embraced a greater variety of topics and has been published at more frequent intervals. It has a record more than forty years long and a character and place of its own. It has made no effort to imitate any weekly journal in this or any other country and has no desire or ambition to do so. Its purpose is to make widely known the chemical knowledge which is the basis of so many of our industries, to advocate such plans for the better organisation of the science as the Society approves and to provide a free medium for the expression of opinion by all who have an idea to put forward or a new fact to announce. The Society, when it decided to publish its *Journal* weekly and to enlarge its scope realised that the experiment would be costly. The Council believed that the experiment would cost about five thousand pounds; the members of Council hoped it would not cost very much more and they considered that

The Messel Medal, 1924

such an expenditure was wise and prudent. Their estimate has been found to be very near the truth. During the last few months of 1922 and the twelve months of 1923 a sum of five thousand pounds was spent in excess of the Society's income. This experience enabled the Council to judge the directions in which further expenditure was justified or should be curtailed. It enabled the Council and the staff to become familiar with the routine of a weekly journal and to improve the organisation. It is needless to say that the members of the Council did not fail to make use of the knowledge thus obtained. By the end of 1923 steps had already been taken to effect the necessary adjustments, and throughout this current year the expenses of the Society have not exceeded the revenue. Many a weekly journal has been started by people with long experience in journals and has been not more successful and not less costly than the Society's *Journal*.

Two Annual Meetings have been held during Dr. Armstrong's tenure of the office of President, the one at Cambridge, the other in Liverpool, very different in their atmosphere and surroundings, but both successful and valuable.

If the publication of a weekly journal was the first preliminary step towards a better organisation of British Chemistry, the next step is the establishment of a Chemistry House where a number of those Societies which are most closely alike in aims and objects may have official quarters. Dr. Armstrong has been active in this matter as in many others; the Leonard bequest has made this project practicable and urgent. Of "Chemistry in the Twentieth Century" and our President's share in it, mention has been made in these columns on more than one occasion; the book has been praised in this *Journal* and in several others, and has been well received everywhere, but somehow it has hardly been received with that enthusiasm which it deserves. It was a noble and an inspiring idea to expound the manner in which British chemists of our own time have helped to build the lofty edifice of chemistry. The execution of the task was equally splendid; the work was done by experts in the various branches of chemistry, speedily, almost hurriedly, and con amore; it has a freshness, a vigour and a variety which make the book very agreeable reading. The reader cannot fail to recognise that each contributor has a story to tell, is proud of it and means to tell it in a convincing and interesting manner. Many members of the Society consider that this book will be the most impressive and durable monument of the retiring President's activities during the last two years and will be for a long period a source of pride and pleasure to British chemists in general and Dr. Armstrong in particular.

Mr. W. J. V. Woolcock is the President Elect and he is no stranger to the members of the Society.

Mr Woolcock has the advantage of knowing how a scientific society should be organised; he had considerable experience in the conduct of the Pharmaceutical Society, of which he was Registrar; as a member of Parliament he learned the refinements of dexterity of speech and the tactful handling of mankind so as to obtain his own way, while leaving others of the opinion that he was carrying out their suggestions. He has had considerable experience in business while acting as Parliamentary Private Secretary to the Minister of Munitions and the Postmaster General, as Assistant Director of Army Contracts and as Chairman of the War Office Committee for the purchase of Medical Supplies, and he has an infinite capacity of taking pains and getting work done and done to the appointed time. The organisation of the Chemical Exhibit at Wembley was very largely his work; the amount of work done by Dr. Levinstein and his committee was immense, but the man behind the gun was Mr. Woolcock and after the exhibit had been arranged he was indefatigable in the attention to detail, getting the exhibits there, seeing they were duly placed, explaining to multitudes of visitors, from Royalty down to editors, the significance of the scientific features and doing all that was possible for one man, and that an exceptional man, to make the Chemical Exhibit a worthy one.

As General Manager of the Association of British Chemical Manufacturers almost from its commencement he has had a difficult task to perform and he has done it well. He has many important pieces of work in front of him; he has to continue the progress of the Bureau of Chemical Abstracts, initiated during Dr. Armstrong's term of office, he has to see that a Chemistry House is duly provided as urged also by his predecessor, and he has several other pieces of constructive work to do, which will fill up his spare time pretty effectually. He has good health, a good appetite for everything, including work, and a youthful appearance; he does not look more than forty, but calculation, based on the known facts of his career, shows that he must be either forty-five years old or approximately that age. So he may be regarded as about to attain the prime of life.

The Messel Medal will be given this year to Viscount Leverhulme. The medal has been designed and the die made by Mr. E. G. Gillick, who is also the artist who made the beautiful Harrison War Memorial at the rooms of the Chemical Society in Burlington House. A photograph of the Messel Medal appears in this issue. The first recipient, as readers of this JOURNAL will remember, was Prof. H. E. Armstrong

The present meeting is the Society's fifth visit to Liverpool. The first meeting held there was in 1886 under the Presidency of Mr. E. K. Muspratt. The second was in 1893, the President being Sir John Evans, F.R.S., and the Lord Mayor of Liverpool, Mr. R. D. Holt, welcomed the members on behalf of the Corporation. The third meeting was in 1902, the President being Mr. Ivan Levinstein

On this occasion the members were welcomed by Principal Dale of University College. The last meeting was in 1913, the president being Prof Marston T. Bogert, and Sir J. S. Harmood Banner, M.P., the Lord Mayor, welcomed the Society on behalf of the Corporation.

The idea of forming the Society originated in Lancashire and among the many distinguished men who took part in the formation of it were Muspratt, Hurter, Mond, Carey, Gamble, Hargreaves, Campbell Brown, and Roscoe, all Lancashire men.

PRESIDENTIAL ADDRESS

By Dr. E. Frankland Armstrong, F.R.S.

Introductory Remarks

The year, which has elapsed since we met at Cambridge, may be regarded justly as a period of steady progress towards the realisation of those ideals of co-operation which many of us consider essential before the chemical profession can attain the status which all chemists claim for it. In spite of this progress, however, the position to my mind is still one of considerable anxiety as there are certain indications of increasing competition between the chemical societies such as is bound to have a serious effect on their financial position if it is not checked. It is more than ever urgent that the energies of those who take an active part in such matters, and they are all too few in number, should be directed to a common object and not dissipated in rival schemes.

The outstanding achievement of the year is indubitably the collective exhibit of the British Chemical Industry at the Wembley Exhibition, including the scientific section. For once—a portent for the future—Chemistry has been first in the field. Our Manufacturers' Association was the first to agree to a collective exhibit and we are the only industry to associate our science so definitely with our trade exhibits. It is a subject for congratulation that the latter part of the scheme originated with our council and that the success of the scientific exhibition is largely due to the energy put into the scheme by Dr. Levinstein, our representative on the joint committee and its chairman. It is difficult to find words to commend the work put into everything connected with Wembley by our President-elect, Mr. Woolcock—for those of us who know him it is most accurate to express our appreciation by saying he has enjoyed it. The scientific publications associated with the Exhibition have particularly been the work of our Society and they form a precedent which I personally hope will often be followed. The popular pamphlets are a real necessity and we must have more of them. Our book, "Chemistry in the XXth Century," is an achievement of which all chemists can feel proud: it can seldom have been the lot of an editor to find so many willing helpers. Lastly, a word of grateful recognition is due to Messrs. Benn Bros., for their enterprise in publishing our productions: it is improbable that a book of this size and nature was ever put more quickly through the press.

Altogether we may feel proud of Wembley and our share in it: may I hope further that we record faithfully the lessons we shall learn from our experience, as I am convinced that much more has to be done by us, both collectively and individually, than in the past to educate both the nation and the individual to the importance and indeed the very meaning of the chemist and his knowledge.

The report of your council details the chief happenings of the year so that I need only refer very briefly to one or two events of outstanding interest. The formation of the Bureau of Chemical Abstracts, under the chairmanship of Prof. J. C. Philip, is perhaps the first step in the unification of all British chemical publications. Composed of representatives of the Chemical Society and of our own Society, it is aiming to secure uniformity in the abstracts on pure and applied chemistry published by the two societies, to prevent any overlap, and to explore the possibility of further co-operation. Progress must necessarily be slow, steps once taken cannot easily be retraced and the problem is the more complex on account of the financial considerations involved. We look to the Bureau during the next five years to unify transactions as well as abstracts and to bring the publications of other societies within its scope. No paper should be abstracted more than once in British literature. It should not be impossible to meet the desire of the smaller specialist societies for more general papers, not always containing new matter, and for fuller abstracts than are at present supplied: it must be remembered that many of their members are not chemists in the strict sense of the word. Our weekly journal, *Chemistry and Industry,* will facilitate the publication of general papers and it should not be impossible to abstract all papers dealing with the glass industry, for example, such as now appear under Group VIII. in our abstracts, once a month, the section being sent by itself to members of the particular society. I attach the greatest importance to the magic of "together"; we must have both ideas and ideals.

The Federal Council must this year play an active part in bringing us together: the representatives of the societies on it must not hold a watching brief, but be prepared actively to engage in constructive effort. I venture to suggest that a definite constructive programme be drawn up by the Federal Council this autumn, or sooner, if it be possible, that it be submitted to the constituent societies for their approval before Christmas so that the way is cleared for immediate action in 1925. I must confess to a feeling of disappointment that the proposals I put forward in outline a year ago have not yet been examined either by the Federal Council or by the various Chemical Societies. Still I realise that in the chemical world things move slowly for various reasons; and it is a source of satisfaction that, in this and some other instances during my term of office as President, seeds have been sown which may lead to important results, although there is but little to show at the moment to some of us.

The most obvious next step towards the consolidation of the chemical profession is the establishment of Chemistry House, where a common meeting ground can be found for most of our societies, and the way made easy for closer co-operation. Such a scheme has long been a dream of the future with many of us: its realisation has been brought nearer by the munificent bequest of the late Mr. Leonard. What I consider to have been a practical scheme was under discussion in the opening months of this year, and I cannot help the feeling that had a little more energy been displayed and a real desire evinced to establish a home we might by now have

been in possession of it under advantageous financial conditions.

During this last year the scheme has received an important impetus; it is for my successor in office and for the general body of chemists, especially the younger ones, to maintain this impetus and accelerate it. So long as the matter is not allowed to drift I shall be well satisfied.

The desiderata for our first scheme are:—

(1) Office accommodation in one building in a convenient central position for the administration of the Chemical Society, Society of Chemical Industry, Association of British Chemical Manufacturers, Institution of Chemical Engineers and such other Societies, including the Institute of Chemistry, as are willing to take part.

(2) Suitable council and committee rooms, so that all such meetings can be held in the one building.

(3) Social meeting rooms, so that the Chemical Industry Club can definitely be associated with Chemistry House from its inception.

(4) Offices for the Bureau of Chemical Abstracts and all other journals issued by the participating societies.

(5) A lecture theatre sufficient for all but the very large meetings.

It is believed that suitable premises could be obtained at a capital cost which is within the range of practical politics.

The ultimate larger scheme which is at present far beyond our realisation would include, in addition to the above, a library, full accommodation for a club including bedrooms and a restaurant, and also for the Institute of Chemistry which is not mentioned more specifically in the foregoing, since it already possesses its own house.

We meet this year in Liverpool, commercially one of the centres of the world. By river, canal, road and rail, the products of industrial Lancashire and Yorkshire are brought to its wharfs to be carried by its ships to all the countries of the world—the ships bring back with them raw products of every kind which pass into Lancashire and Yorkshire to be manufactured. Liverpool has made much of its opportunities, its citizens are justly proud of their city, of its civic and corporate life and of its University whose hospitality we are enjoying to-day. The very existence of the University, munificently endowed by local generosity, though its needs are still many, proves the recognition which Liverpool gives to science. That our science in particular is not forgotten is shown by the fact that there are, or soon will be, five chairs in Chemistry here. Chemical science is also represented locally by active sections of our own society and of the Institute of Chemistry. If such a gathering as this may leave a message behind it, surely, in congratulating Liverpool on all that it has achieved in the past, in honouring its many great traditions, we may urge it in the future to redouble its encouragement of science and the prosecution of scientific research, and to be ever zealous in applying the results of science for the service of its citizens.

SOME RECENT WORK ON THE SOIL

The ultimate practical object of the study of the soil in relation to plant growth is the improvement and standardisation of methods of soil management—or, in other words, the achievement of as full a control as possible of the processes going on in the soil which affect the growth of economic plants for good or ill. It is evident that before great advances on established principles of soil management can be made, the fundamentals of soil science must be put on a firm basis. All aspects of the subject require investigation whether or not there is prospect of an immediate practical application.

Soil problems are, however, notoriously complicated and the difficulty of disentangling the factors involved is very great, so that, in spite of the increasing volume of work turned out, it will probably be a long time before cut and dried schemes for soil management under widely varying conditions, based on accurately known facts, can be drawn up with confidence.

Much useful work on questions of fundamental importance in soil science has been carried out in the last few years, particularly in connexion with the physical properties of soils and with the micro-organisms and their activities.

The water relations of soil are of primary importance both in respect of the direct supply of water to the plant and of the effect upon the tilth of alternate shrinking and swelling brought about by varying moisture content. Recent work has shown that the nature and amount of the colloids present determines these relationships to a very large extent, and a good deal of attention has been given to the study of the evaporation of water from soils and other colloidal materials. It has long been realised that the old division of soil water into hygroscopic, capillary and gravitational water was incomplete and unsatisfactory, and in 1921 Bouyoucos (*J. Agric. Res.*, **20**, 587; *Soil Sci.*, **11**, 33, 255), applying dilatometer and freezing-point methods to the study of the soil solution *in situ*, came to the conclusion that some of the water does not occur actually as liquid but is "unfree" and must be physically adsorbed or chemically combined or in solid solution. Bouyoucos' interpretation of his results has been criticised from various points of view by Keen (*Trans. Faraday Soc.*, 1922, **17**, 228), Parker (*Soil Sci.*, 1922, **13**, 43; *J. Am. Chem. Soc.*, 1923, **43**, 1011) and Fisher (*J. Phys. Chem.*, 1924, **28**, 360). The curve for the evaporation of moisture from soil is found to be of a type peculiar to materials containing both colloidal and non-colloidal substances and is determined by evaporation at the same time of imbibitional or gel water held by the colloid and of capillary or interstitial water held between the soil grains (Fisher, *Proc. Roy. Soc.* (*A*), 1923, **103**, 139, 664; *J. Agric. Sci.*, 1923, **13**, 121; 1924, **14**, 204).

Wilsdon's investigations on the distribution of water in soils indicated a reticulate structure for the colloids present. It is now generally accepted that the colloidal coating round the soil grains is in the form of an inelastic emulsoid gel consisting of vesicles enclosed by walls and that water held by the swollen

gel is partly adsorbed in the walls and partly fills the vesicles. According to Hardy (*J. Agric. Sci.*, 1923, **13**, 243) the shrinkage of moist soils and clays on drying is due solely to loss of "vesicular" water. The varying behaviour as regards shrinkage of soils of similar colloid content but belonging to different geological types is explained as due to a specificity in soil colloids, which differ in the ratio of the amount of water held as adsorbed (hygroscopic) water to that held in the vesicles. A simple means of measuring shrinkage of clays and soils has been devised by Haines (*J. Agric. Sci.*, 1923, **13**, 296), who has studied the details of the process. He shows that it takes place in two stages, both having a linear relationship to the moisture content.

Another important function of the colloid constituents of soil which has a direct effect upon moisture relationships and tilth is flocculation. The mechanism of the flocculation of soils by lime and chalk has been investigated by Comber (*J. Agric. Sci.*, 1921, **11**. 450; 1922, **12**, 372); and the practical effect of chalking in reducing the power required to carry out cultivation operations has been demonstrated at Rothamsted by dynamometer measurements of the draw-bar pull on a plough and other implements. On chalked land there is a saving of power which under certain soil conditions may amount to as much as 15 per cent.

The physico-chemical investigation of soils would be rendered easier if a recognised system of characterisation by one or more physical properties existed. As pointed out by Robinson (*Trans. Faraday Soc.*, 1922, **17**, 224), such physical measurements must be capable of application to soil in its natural condition in the field and the determinations must be simple so that large numbers of soils can be examined. The density, pore space, water-holding capacity and swelling of soils on moistening are known to be related to the percentage of clay or organic matter (Keen and Raczkowski, *J. Agric. Sci.*, 1921, **11**, 441), and the possibility of utilising one or more of these constants as a kind of soil index is under investigation. For the genetic classification of soils, a mechanical analysis is necessary, and if the difficulties of ensuring complete dispersion of the soil sample in water can be overcome, the more rapid and convenient methods for this analysis which have been worked out recently will prove of great value (*cf.* Joseph and Martin, *J. Agric. Sci.*, 1923, **11**, 293; Robinson, *J. Agric. Sci.*, 1922, **12**. 306; Odén, *Trans. Faraday Soc.*, 1922, **17**, 327; Jennings *et al.*, *Soil Sci.*, 1922, **14**, 485; Krauss, *Int. Mitt. Bodenkunde*, 1923, **13**, 147).

In addition to investigations such as those already referred to, which deal with the soil water *in situ*, many attempts have been made to separate the solution and study it independently. Parker (*Soil Sci.*, 1921, **12**, 209) uses a displacement method which gives good results except, perhaps, with heavy soils. The use of high pressures has also been tried (Lipman, Burgess, *Soil Sci.*, 1922, **14**, 159) and other methods are advocated by Tulaikov and Kusmin (*Soil Sci.*, 1923, **15**, 235) and by Groh (*Int. Mitt. Bodenkunde*, 1923, **13**, 107). Burd and Martin (*J. Agric. Sci.*, 1923, **13**, 265) have recently combined the displacement and pressure methods, and bring forward a good deal of evidence to show that the displaced liquid does really represent the soil solution as it exists in the soil under natural conditions, at all events when more or less coarse-grained soils are used. Their results in the main confirm those of Parker, but it is perhaps too early to say that the difficulties in the way of obtaining the actual soil solution have been finally overcome. If the hypothesis, mentioned above, as to the manner in which water is held in the soil is correct, it is obvious that when much colloidal material is present, as in heavy soils, the separation of the soil solution as such is certain to be difficult.

Turning now to some recent work on the activities of the soil population, it is becoming more and more evident that, in regard to the supply of nitrogen, the part played by soil organisms as competitors with our crops is as important as their rôle in rendering nitrogen available. Not only is there, under certain conditions, an actual loss of gaseous nitrogen due to the action of certain organisms; but in addition, some of the nitrate produced by the breaking down of organic nitrogenous materials is utilised by bacteria, fungi and other organisms for their own purposes, and though such nitrogen is not lost to the soil, a certain proportion will remain permanently out of reach of plants. Such nitrate consumption has been shown to be especially active when the organic matter available as the source of energy for the micro-organisms contains only a low percentage of nitrogen. As the result of some work by American investigators (Lyon, Bizzell and Wilson, *J. Amer. Soc. Agron.*, 1923, **15**, 457), it appears that the retarding effect of growing plants on the production of nitrates, which is a well-known phenomenon, is probably to be accounted for by the fact that the organic matter arising from the roots has a low nitrogen content, and consequently nitrate consumption by soil organisms is promoted in the immediate neighbourhood of the plants.

On the other side of the account, the bacterial fixation of nitrogen and the conditions under which the process is favoured or checked continue to be studied in detail. Claims have been put forward from time to time, most recently by Wann (*Amer. J. Bot.*, 1922, **8**, 1), that soil algæ also possess the power of fixing atmospheric nitrogen. It has, however, been shown at Rothamsted by Bristol and Page (*Ann. App. Biol.*, 1923, **10**, 378), that the analytical methods employed by Wann were open to criticism, and a careful repetition of the experiments produced no evidence of the ability of algæ to fix nitrogen.

So far as is known at present, the chief economic significance of the soil algæ, whose mode of nutrition when living below the surface of the soil, away from light, is wholly saprophytic, lies in their competition with crops for the available nitrogen. Excluding pathogenic forms, this is probably also the case with the fungi of the soil. Unfortunately, no really satisfactory technique has yet been found for counting algæ and fungi though it is known that they are present in the soil in very large numbers. The whole

subject is one of great interest and is being actively pursued at Rothamsted and elsewhere.

A considerable amount of quantitative data has been obtained on the relations between beneficial soil bacteria and protozoa, the work arising out of Russell and Hutchinson's hypothesis that bacterial numbers in field soil are normally limited by the activities of protozoa. Cutler, Crump and Sandon (*Phil. Trans.* (*B*), 1922, **211**, 317) have demonstrated that there is an inverse relationship between the numbers of the active forms of certain protozoa and of bacteria; and, in continuation of this work, it was found that when bacteria only are introduced into *sterilised* soil, the numbers remain high but that in the presence of protozoa also, they are very much reduced (Cutler, *Ann. App. Biol.*, 1923, **10**, 137). On the other hand, the activities of one group of bacteria—*Azotobacter*, nitrogen-fixing organisms—appear to be favoured when soil protozoa are present (Nasir, *Ann. App. Biol.*, 1923, **10**, 122); and Waksman and Starkey (*Soil Sci.*, 1923, **16**) maintain that soil fungi are the chief factor limiting the numbers of bacteria under normal conditions by their competition for the available supply of food. It is not unlikely that both fungi and protozoa are important in this connexion and there may be other factors. The work on this subject illustrates the complexity of soil problems and the difficulties in the way of any attempt at control of the soil population

The equilibrium between the various groups of soil organisms can, however, be disturbed and the balance altered by such means as "partial sterilisation" by heat or chemical treatment; and with further and more intimate knowledge of the soil population there is hope of useful development towards control.

The literature dealing with soil problems is very scattered and one welcomes the appearance of books in which the results already arrived at are brought together and correlated. Two have come to hand recently of quite different types. Drs. Honcamp and Nolte* ("Agrikulturchemie"), have collected the agricultural chemical literature published in the years 1914 1920 and review the more important advances during that period. The volume is one of a series dealing in a similar manner with various branches of natural science and it is hoped to include later work in future editions. The book is divided into four sections dealing respectively with Soils, Plant Nutrition, Animal Nutrition, and Research Methods. References are included to all the papers mentioned. German work is to some extent given prominence, but this will tend to make the book more rather than less useful to English investigators and teachers, since work published in German periodicals which are not always easily accessible, is included. The collection and sifting of the material must have been a laborious task, which the authors have accomplished with a considerable measure of success.

The other book† ("Soil Management"), by Mr. Firman E. Bear, Professor of Soils in the Ohio State University, is written with the purpose of indicating the application of established facts to the management of soils and is primarily intended for use in agricultural colleges. Reference to the Table of Contents shows that the subject-matter is treated under the main headings Requirements of Crops, Characteristics of Soils, Utilising, Conserving, and Supplementing Soil Resources; but these divisions are not indicated in the body of the book, with the result that the sequence of the chapters is sometimes difficult to follow. Chapter VI, for example, is on biological processes in soils, but not till Chapter XIII do we get an account of the organic matter of soils, the intervening chapters being devoted to the physical properties and cultivation: again, chapters on limestone economy and liming materials are separated by discussions of animal manures and soil sanitation. The arrangement hardly seems logical.

When this has been said in criticism of the general plan, it must be added, however, that the book is full of accurate information which will be most valuable to agricultural students, clearly set down and illustrated from the results of field experiments. The treatment of the nitrogen question and the economic use of fertilisers generally seems to the writer admirable. Prof. Bear throughout lays special stress on the immense importance of taking full advantage of natural nitrogen-fixing agencies by the proper use of leguminous crops for maintaining and increasing the fertility of the soil. NITROGEN FIXATION IN FRANCE

The last report of the "Azote Français" summarises in an interesting fashion the researches and results obtained by this company in the production of nitrogen. Results obtained with the arc process show (1) the industrial application of a very simple and cheap furnace with a yield at least comparable to that of arc furnaces now working; (2) the final perfecting of the recovery of the oxides of nitrogen produced in the arc process by cooling without risk, and in the form of liquid nitrogen peroxide. This recovery enables the yield to be greatly increased, and the production of a concentrated product in which the unit of fixed nitrogen possesses higher market value. (3) The direct manufacture from this peroxide of concentrated chemically pure nitric acid, of metallic nitrites and of nitro compounds At present, despite improvements, the arc process gives barely 12 per cent. of the theoretical yield but this, however, is a paying quantity. The company owns at Luchon Marignac one of eight groups capable of producing 33,000 tons of cyanamide annually. Two continuous furnaces for nitrifying the carbide are now being worked at the Cie d'Electricité Industrielle at Marignac, with yields higher than those of the discontinuous furnaces employed in other works. For the production of ammonia with electrolytic hydrogen the company has obtained the rights of the Pechkranz electrolyser in France.

FUEL ECONOMY QUESTIONS *

By H. WOMERSLEY

Owing to present economic conditions, we are all thoroughly alive to the necessity of fuel economy, and the aim of this short paper is to point out a few of the questions that emerge in regard to this problem.

In the first place, I would emphasise the fact that a steam-boiler plant is a manufacturing department in itself. Too often does one fail to realise that it is concerned with raw material and finished product. We start with coal or other fuel, and by its means we convert water into the product, steam. In other words we buy heat, and after conversion into a more usable form, sell it again to the other departments. It stands to reason, therefore, that to make the plant a paying concern, we must know :—

1. How much heat we are buying.
2. What our conversion losses are or, conversely, our efficiency of conversion.
3. The amount of steam taken by departments.

Now, the heat we purchase is, of course, the calorific value, whether we express it as B.Th.U.s per lb., Calories per lb., or Calories per kg.

This is the point that I wish to make. Are we justified in buying on this factor alone, or, as is usually done (although it amounts to the same thing) on the ash and moisture content ? My own opinion is that it all depends on the coalfield from which supplies are drawn. If all supplies come from one field, then we can be guided by this factor, but the coals vary so much in different districts in regard to other qualities, that practical experience must be employed to discriminate in cases where otherwise the calorific values may be the same.

In this respect different coals have different rates of combustion under similar conditions. Northern coals are, as a rule, open and quick burning, whilst Somerset coals are almost non-burning, at least, very slow. Forest of Dean coals, on the other hand, are intermediate, and considering freightage, are the most satisfactory for steam raising in this district. Apropos of this rate of burning we tried to burn Somerset coals some time ago, and from that experience we calculated that to get our normal output of steam, we should have had to, at least, treble the boiler plant, which, with its resultant increase of labour, would have made it a very dear proposition in spite of a lower price for the coal. As to the cause of this character, it would appear, from Illingworth's work, to have something to do with the resinous constituents of coal, and thus neither an elementary or a proximate analysis would indicate it.

There is just another point here in regard to the purchase of low-grade fuels. It is well known that a higher quality coal can be burnt at a higher efficiency, and when this is taken into account together with the smaller amount of labour required for handling ash and other work, it will be seen that a higher price than is proportionate to its increased calorific value can be profitably paid. Conversely, coal of lower value is not necessarily a paying proposition.

The following figures may help to make this clear :—

	Low quality	High quality	
B.Th.U. per lb.	12,500	14,500	
Ash content	12%	6%	
Price per ton	22/-	27/-	Equiv. price 25/6 on B.Th.U. basis
Max. efficiency week in, week out	75%	80%	
Coal per 80,000 lb. steam per hour	4·32 tons	3·49 tons	
Cost of coal per hour	95/-	94·3/-	
Tons ashes per hour	0·52 tons	0·21 tons	
Cost of ash removal at at 2/- per ton	1·04/-	0·42/-	

CONTROL OF THE BOILER PLANT

Now I come to the boiler itself. We can, and to know what we are doing, must regard the boiler plant as a chemical factory in itself. Thus it is essential to know with reasonable accuracy, how much coal we are burning, and how much steam we are getting as a result. In other words, we must find whether we are getting the best efficiency out of it.

I do not propose to say more about the importance of the carbon dioxide in the gases, except to emphasise the importance of continuous tests. Snap tests for controlling fire are of little use, in fact, by noting the temperature at the end of the centre tubes of Lancashire boilers, a practical man can exercise quite as much control over the fires.

To control the fires the carbon dioxide record from the centre tubes is alone sufficient, always avoiding carbon monoxide, of course, and with a recorder installed, then systematic snap tests at such important points as the side flues, immediately before the boiler, dampers are very necessary for detecting leakages in the flues themselves, and thus enabling the resultant losses to be avoided. Another very useful implement is the electrical pyrometer, especially if this also has a continuous recording apparatus attached. At the centre tubes of Lancashire boilers where a carbon dioxide apparatus is installed, this is not essential, but at the position in the side flues already alluded to, it should be used in conjunction with the carbon dioxide apparatus. On water-tube boilers, positions for test are chosen with the same aims in view, viz., control of fires, and detection of leakage of air through brickwork. Where economisers are installed similar observations should be made continuously at the gas inlet and exit.

As coal consists mainly of carbon, the chief product is carbon dioxide, and this is used as the control. Theoretically, as the molecular weight of O_2 occupies the same volume as the molecular weight of CO_2, complete combustion of carbon should result in a gas containing 21 per cent. carbon dioxide when such carbon is burnt in air. Practical considerations, however, require an excess of air, otherwise there is a tendency to only partial combustion, resulting in carbon monoxide. When we come to coal, we get a reduction also in the theoretical percentage of carbon dioxide that we can obtain, due to the hydrogen in it. With the usual semi-

* Read before the Bristol Section on March 6, 1924.

gallon, if the Permutite is partially exhausted, the reaction is just as likely to go the reverse way, and the total hardness of the water be increased.

Another plant, that by the Kestner company, is now being pushed on the English market, and their system of treating the water by the excess alkali and heat of the continuously blown-down water from the boilers, together with a degasifying plant, seems to the author to require the careful consideration of those concerned with boiler plants, especially where new plants are being installed.

In conclusion I have to express my indebtedness to Messrs C. Thomas and Bros., Ltd., for permission to publish these notes.

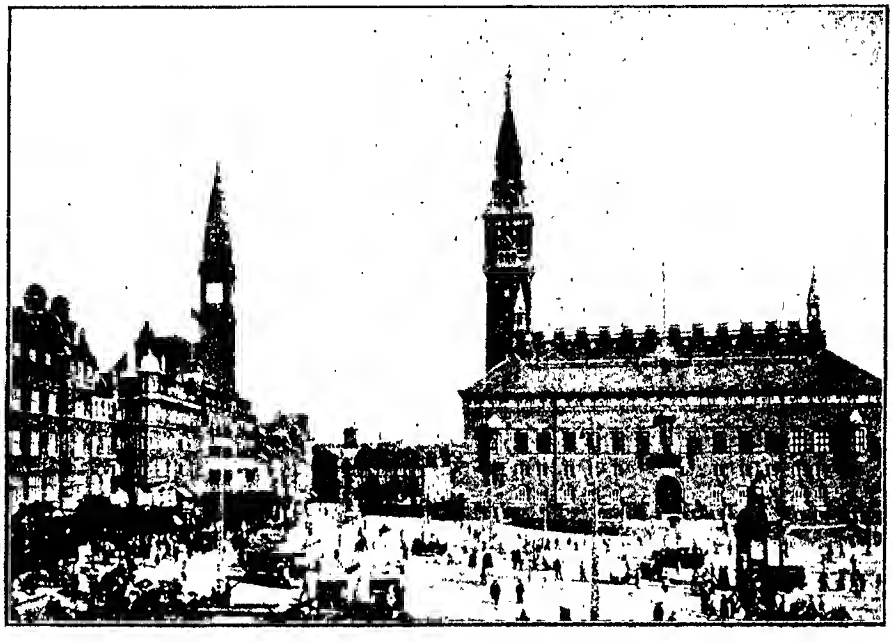
Broad Plain Soap Works,
Bristol.

THE INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY

The Union Internationale de la Chimie Pure et Appliquée held its Annual Meeting in Copenhagen from June 26 to July 1. These annual meetings have a character of their own: some international bodies divide themselves into sections at which papers are read and discussions are encouraged; disputation is an ancient method of learning a subject; an old teacher of law wrote in the fifteenth century, "Home ne scavera de quel metall un campane est, si ne soit bien baté, ne le ley bien conus sans disputation." The Union Internationale divides itself into a variety of committees which after much debate internal draw up reports of considerable value. Intervals are usually found for lunches, receptions and banquets and in addition to the official feasts some of the more frivolous members have been found who despise not the small social parties graced with flasks of Samian and of Chian wine. The Union Internationale has held meetings in Brussels, Rome, Lyons, Cambridge and Copenhagen These have been attended by thirty or forty chemists of world-wide reputation, by as many others whose fame only reaches the borders of one country or one branch of chemistry and by some others who can only be considered as camp followers, wolves masquerading as chemists or whatever is the polite description.

Four English professors upheld the dignity of British chemistry, Profs. Pope, Drummond, Gibson and Harden; other familiar figures at the gathering were Messieurs Béhal, Lindet, Moureu, Matignon, Marquis, Marie, Kling, Nasini, Giordani, Bancroft, Noyes, Minovici, Votocek, Swartz, Cohen, Jorissen, Timmermans, Profs. Biilmann, Bjerrum, Bronsted and Holleman with several others, whose names and researches would be familiar to our readers if space permitted a nearly complete list of the delegates.



City Hall Square, Copenhagen

Of the places selected for these Annual Meetings Copenhagen is perhaps the least known to the majority of chemists, yet civilization advanced as rapidly, and by very similar stages, in Denmark as

in England or Belgium or Holland or the north of France. Denmark is a beautiful green country, well cultivated with beech woods and small lakes surrounded by higher ground, which it would be flattery to describe as hills. It has cattle tethered in the fields and red-tiled farm houses, which are certainly clean and seem to be prosperous. Copenhagen itself is full of handsome buildings, many of them palaces; its Town Hall is a striking example of modern Danish architecture and the reception given to the Union by the Civic dignatories in it was a delightful function. When we reached Copenhagen the school terms were just at an end and those boys and girls who were to proceed to the University as full-fledged students celebrated the occasion with due ceremony. A brake with four horses is adorned with green leaves, with flowers and with paper streamers. A dozen or so boys with white caps drive through the town in this equipage cheering and making other more or less musical noises. Similar parties of fair-haired, merry girls, dressed in white, drive in state laughing and cheering. It is evidently a red-letter day to emerge from the chrysalis state of school to the butterfly existence of the University of Copenhagen.

The Union Internationale is still busy with its own organisation. It does not yet include all the countries, its constitution is no longer adequate to its numbers. This year the Federal Council submitted a number of resolutions to ensure that decisions of the Union shall not become effective until an opportunity has been given to all those concerned to express their opinions. These resolutions were, with trifling modifications, adopted by the Union Internationale, and a small committee, consisting of four or five, has been appointed to consider how the organisation and procedure of the Union can be improved. Formal notice was given at Copenhagen that at the next meeting a proposition will be made for a revision of the rules so as to admit into the Union Internationale all countries who are members of the League of Nations. This will enable two or three important countries, now outside the Union, to become part of it, and perhaps by that time it will mean the inclusion of all the countries not now represented. It seems there is no opposition to this scheme; it has for some time been advocated by the French delegates, and experience has shown that in chemical matters the French require neither advice nor encouragement to persuade them to take a generous view of any situation.

The banquet was, as usual, a brilliant affair; speeches were made by Mr. Larsen, the Danish engineer, by Sir William Pope, Mr. Warming, Prof. Nasini, Prof. Bancroft and Prof. Béhal, who though only now in middle life was a member of the Institute when some of us were mere boys. Next year the Roumanian Government has invited the Union to meet in Bukharest, and the invitation has been accepted with joy and acclamation. However good Bukharest may be, those who attended the meeting in Copenhagen will long treasure the recollection of this pleasant City, its old-fashioned canals and harbours, its beautiful sea-shore and suburbs, its forests, its air of refinement, its splendid hospitality and its charming people.

WORLD POWER CONFERENCE AT WEMBLEY

The First Week's Papers

(From our Special Correspondent)

The first World Power Conference, organised by the British Electrical and Allied Manufacturers' Association, which is being held at Wembley from June 30 to July 12, is naturally of the greatest possible interest to the chemical industries, both directly since a number of papers that have been presented are on purely chemical engineering subjects, and, secondly, because every industry is very closely concerned indeed with all that relates to power.

As is well-known, the World Power Conference has been called to consider from an international point of view the whole question of the industrial and scientific sources of power and how they may be improved, conserved, and adjusted. It has called together civil, electrical, mechanical, marine and mining engineers, and other technical and scientific experts from nearly 40 different countries, and more than 400 papers are being presented, the last number of the printed schedule being 417.

It is, of course, impossible to give any adequate idea of the vast mass of material represented by these papers, although a number of them are very short, and, frankly, not very important, whilst the discussions are proceeding for nearly a fortnight. The best thing to do is to send for a schedule list of all the papers to the Offices of the World Power Conference, 36-8 Kingsway, London, W.C.2, the price of the different reprints being shown.

The papers under consideration in the first week include the subjects of the fuel and power resources of the various countries in the world, the economic aspect of power, especially the consideration of future developments, steam generation and utilisation, the preparation of fuels, illumination, and water power in all its branches. The latter, quite rightly, occupied a very large part of the proceedings, and over 50 papers were presented on this subject, dealing in the first place with the potential resources of many countries in the world, including Great Britain, Ireland, Holland, Hungary, Germany, India, Japan, New Zealand, Norway, Spain, Siberia, Sweden Switzerland, China, and Esthonia. Very valuable were many of the contributions relating to the troubles and difficulties of hydro-electric power and methods for improving the efficiency, and the papers in this section dealt with such varied subjects as the Kaplan turbine, the general conditions of water storage, ice troubles, general turbine design, the construction of dams and the developments in low-head work.

There is no question that a silent revolution in power production is proceeding in most countries, to an extent that is not generally realised in Great Britain. To-day, over 25,000,000 h.p. of water power is in operation, of which nearly half is in the United States, and more plant is being continually installed. According to a recent report of the United

States Geological Survey, the available inland water power of the world is over 425,000,000 h.p., and the greatest potential source of energy is in Africa, the Congo and its tributaries. In Great Britain we have about 1,000,000 h.p. available, all these figures being, of course, exclusive of the tides.

The section devoted to the preparation of fuels, comprising 18 papers, is also an interesting one, dealing with the complete gasification of coal, the utilisation of peat, low temperature carbonisation, oil refining, the use of wood refuse for power production, the hydrogenation of coal, and pulverised fuel.

Low-temperature carbonisation and hydrogenation of coal will be dealt with in the next article along with the gas and fuel section. Incidentally it may be mentioned that the method of attempting to divide up the papers into groups seems to be somewhat illogical and has not unnaturally given rise to some considerable confusion and much overlapping in the discussions.

Pulverised fuel, now making enormous strides in steam generation throughout the world, was dealt with very inadequately, and the papers and discussions give little idea of the real facts of the case. Strangely enough also, the latest remarkable developments in mechanical stoking, such as the suspended firebrick arch allowing single stokers up to 24 feet wide to be constructed, water cooled travelling grates, easy adjustment of the air supply at different stages of the travel, and furnace walls composed of water-cooled steel tubes, seem to have been given little attention. Mr. John Anderson, of Milwaukee, however, who is responsible for the first large power station in the world—Lakeside—to be equipped with pulverised fuel, and which remains to-day, as in 1920, the most efficient boiler plant in the world, enlivened the discussion.

As showing also the possibilities of power production from what might be termed rather unusual sources, comprising Section " F " of the list of papers, we had three papers, strangely enough all from Danish engineers, dealing with the utilisation of the wind, a contribution describing the well-known Larderello power station in Italy operated by natural steam from volcanic regions, and a paper on alcohol as a source of power.

It is curious that the modern scientific windmill, as used particularly in Holland, Germany, and Scandinavia, should be so completely neglected in Great Britain, as it is in many cases an invaluable source of energy for electric lighting and pumping on a relatively small scale, such as in agriculture, and up-to-date machines are constructed and supplied by British makers. The use of volcanic steam for power generation is certainly a striking example of the ingenuity of the modern engineer, but in spite of this one is glad to know that such developments are impossible in Great Britain

The fact that only one paper was given on such an important subject as power alcohol is certainly only one example of a number showing that the organisation of the next World Power Conference can be very considerably improved. Power alcohol is of particular importance to Great Britain because of the serious neglect of the cultivation of our soil and the fact that we do not possess natural liquid fuels, such as petroleum. There is no reason why several million acres of land should not be devoted to the scientific cultivation of potatoes for the manufacture of power alcohol.

Certainly the most interesting section, both to the chemical engineer and the general steam and power user is " D1," that relating to steam generation, and the 30 papers dealt with such varied subjects as the " Benson " super-pressure steam generator, the 1200 lb. pressure water-tube boilers now being erected in the United States, the production of a new steel alloy that maintains its strength even at 1920° F. —and of the utmost importance therefore for high-pressure steam work—the necessity for the determination of carbon monoxide and unburnt products in flue gases, the " Blomquist " horizontal revolving tube high pressure boiler, a review of recent developments in steam practice by P. Junkersfeld and G. Orrok (U.S.A.), high pressure water-tube boilers by Dr. Jacobus, several very important German papers on high pressure steam, including those of Dr. F Munzinger, and also by O. H. Hartmann. Finally also W. L. R. Emmet (U.S.A.) gave a paper on his remarkable mercury boiler and turbine.

Closely allied to these subjects is " D2," on steam turbines, comprising papers by the Hon. Sir Charles A. Parsons, C. F. Stork (Holland), V. Nordstrom (Sweden), and F. Hodgkinson (U.S.A.). It is, of course, impossible to do justice to fascinating subjects of this description within the space of an article, and the same applies to the discussion, in which each speaker was allowed about five minutes.

Certainly one of the most remarkable tendencies of the last few years in steam and power generation has been the rapid increase in steam pressure as applied to water-tube boilers. It took well over 100 years of evolution in steam boiler construction to reach 200 lb. working pressure, and not very long ago this was the standard power station practice. To-day 350 lb. per square in. and 700° F. temperature represent average steaming conditions for super station conditions, but this is now also passing and the era of say 500–600 lb. is approaching.

Most interest attaches, however, as far as ordinary water-tube boilers are concerned, to the remarkable work being carried out, both in the United States and Germany in the use of steam at about 1000 lb pressure. The best known installation in America has drums of steel forgings 4-in. thick, weighing 70 tons, and the working pressure is to be 1200 lb. It is expected that, on these lines, well over 25 per cent. thermal efficiency will be obtained from the raw coal to the switchboard, using condensing steam turbines. Even more remarkable is the work represented by the super-pressure steam generator, such as the " Blomquist " revolving wide-bore tube boiler, in which the problem of ebullition in tubes is surmounted by submitting the water contents to centrifugal action, the working pressure being 1500 lb. per sq. in. The " Benson " generator at 3200 lb. pressure has already been described in these columns, and it will be remembered that water at 706° F. under the above conditions of pressure

being converted into steam at the same volume without the absorption of latent heat.

The highly efficient principle of "bleeder" or pass-out steam was also discussed, that is the prevention of the serious steam loss in the condenser by using the exhaust steam from turbines, high-speed vertical engines, or slow-speed reciprocating engines in boiling and general process work. Although this method is now being extensively used in Germany, it has been developed to an equal extent by British engineers, and the fault of the comparatively slow progress made in this country until quite recently lies with the steam user and not the engine builder.

In the group of papers relating to the more efficient utilisation of steam perhaps the most important was that by Dr. Ruths, the well-known Swedish engineer, describing his now well-known steam accumulator, which is meeting with a wide application on the continent, especially Germany and Scandinavia. The principle is a particularly important one for the chemical industries, with the irregular demand for steam, and allows for example the use of high pressure steam generation, and the production of power by the drop in the pressure, as already discussed, through an engine or turbine, combined with the utilisation of all the exhaust steam for process work, irrespective of the fluctuating demand, by the use of the steam accumulator, which acts as a "fly-wheel" of steam supply for the whole factory, so that a condenser is not necessary at all as with the ordinary pass-out principle.

THE FRENCH CERAMIC CONGRESS

The Technical Congress of the Ceramic Industry was held in Paris from June 2-6 MM. Frion and Linke studied the utilisation of liquid fuels in pottery kilns and described tests carried out for two years at Sèvres with crude oil and tar. From 50 trials it was found that one kg. of crude oil replaced 7 kg. of wood, an economy of over 50 per cent of heat. One furnace, consuming 420 francs worth of wood for each firing, consumed fuel oil worth 250 francs. In addition the time of firing was reduced from 24 to 11 hours. MM. Hachon and Lecallier discussed artificial or natural draught and concluded that if artificial draught costs more than natural draught, it possesses many advantages, such as quicker working, more regular heating, and its use for cooling. M. M. E. Lafon, comparing natural with artificial draught, favoured the former.

The use of pulverised fuel was described by M. Coquillat, who stated that the process was advantageous and economical, although it still required study. Discontinuous or cellular driers were dealt with by M. Cazeneuve, and compared with continuous driers. In a monographic study on ceramic ovens Mons. Frion concluded that the Hoffmann furnace had been not sufficiently studied for typical forms to be described. The results obtained, however, were useful as a guide to the ceramist.

The Congress concluded with visits to ceramic works, quarries, and brick factories.

FORTHCOMING EVENTS

July [illegible]. **The Institute of Chemistry Students' Association (London).** Visit of Chemical Students to Wembley. At 9.45 a.m. an Inaugural Meeting will be held at University College, Gower Street, W.C. 1, at which the President of the Institute, Prof. G. G. Henderson, LL.D., F.R.S., will take the chair. Mr. W. J. U. Woolcock, General Organiser of the Chemical Section of the Exhibition and President-elect of the Society of Chemical Industry, will explain the objects of the exhibits and the special features of interest. Professor W. P. Wynne, F.R.S., President of the Chemical Society, hopes to support the speaker at the meeting. The cost of the visit, including return ticket to Wembley, entrance to the Exhibition, and ticket for luncheon, will be 5s. Further information can be obtained from Mr. G. S. W. Marlow, 30, Russell Square, London, W.C. 1, and applications should be made not later than June 28.

July 16. **Institution of Chemical Engineers**, Annual Corporate Meeting, at the Hotel Cecil, Strand, London, W.C. 2, at 11 a.m. At 12 noon the presidential address will be delivered by Sir Arthur Duckham. After luncheon at 1 p.m. (price 6s., excluding wines) Sir F. Nathan will review the work of the Educational Committee on "The Training of a Chemical Engineer," and at 3.30 p.m. the following papers will be read:—(1) "Self-balancing Centrifugals," by E. A. Alliott. (2) "Evaporation in Currents of Air," by G. W. Himus and J. W. Hinchley. After tea, at 5 p.m., members will proceed to the British Empire Exhibition, and a tour of the Chemical Hall will be made under the guidance of Mr. W. J. U. Woolcock.

Sept. 8 to 11. **Institute of Metals.** Annual Autumn Meeting, to be opened at the Institution of Mechanical Engineers, when W. M. Corse, S.B., will deliver the third annual Autumn Lecture. On September 9 the morning will be devoted to reading and discussion of papers, followed by luncheon at the Connaught Rooms, Kingsway, the afternoon to be spent at the British Empire Exhibition. On September 10 further papers will be presented for discussion, the afternoon being devoted to visits to works. A reception will be held in the evening at the National Physical Laboratory, Teddington. A detailed programme will be issued in August.

Sept. 15. **British Empire Exhibition.** Conferences of Engineering Societies, to be held in Conference Hall No. 4, at 10.30 a.m. Short papers on various Engineering Subjects will be read and discussed. Further information and tickets may be obtained from the Secretary, Society of Engineers, 17, Victoria Street, Westminster, S.W. 1.

Prof. W. L. Bragg has been elected Dean of the Faculty of Science, W. Baker, M.Sc., and B. Cavanagh, B.A., B.Sc., become assistant lecturers in chemistry, and Dr. P. W. Clutterbuck becomes demonstrator in physiological chemistry in Manchester University.

THE INSTITUTION OF CHEMICAL ENGINEERS

The Council of the Institution met on July 2, 1924. The Annual Report was read and approved for presentation to the Annual Corporate Meeting. Owing to the fact that the organising work of the Institution is largely completed and its public work was assuming greater importance, it was decided that more publicity should be given to its doings.

Elections took place as follows :—

Members.—Charles Davidson, Alexander Cross and Sons, Ltd ; Harry Mackenzie Ridge, Ridge Roasting Furnace and Engineering Co., Ltd.

Associate Members.—Harold Joseph Hailstone, Rochdale Corporation Gas Works ; William Charles Peck, Messrs. Burgoyne Burbridges and Co., Ltd. ; Harry William Webb, Cardiff Technical College ; E. P. B. Wilson, Shanghai Municipal Council.

Student.—David Robertson Bean.

Correspondence was read from the President of the American Institute of Chemical Engineers suggesting a joint meeting in England in July, 1925, when about fifty members of the American Institute would be able to attend. A cable was despatched cordially accepting the suggestion. Steps were taken at once to arrange this joint meeting.

The arrangements for the second Annual Corporate Meeting on July 16 were considered and approved. An account of the arrangements will be found under Fortheoming Events on page 721.

SEVENTH DOMINION CONVENTION OF CHEMISTS

The Annual Convention of Canadian Chemists opened its sessions at Kingston on May 27th last with the meeting of the Canadian Sections of the Society of Chemical Industry. Mr. S. J. Cook briefly outlined production values in the various branches of Canada's chemical industry in his address entitled "Statistics Reflecting Recent Progress in Chemical Industries." Mr. R. T. Elworthy discussed developments of the natural gas resources of Canada, which were situated chiefly in southwestern Ontario and in certain parts of Alberta. The Wainwright field in Alberta had an intermittent flow of 600 barrels per day, and the product was an emulsion of about 60 per cent. oil and 40 per cent. water. No. 1 gas well in the Foremost field near Calgary had a helium content of 2 per cent. and 98 per cent. methane. Mention was made of the possible uses of these natural gas resources, of the possibility of recovering natural-gas gasoline, the production of carbon black from natural gas, and lastly the possibility of obtaining helium on a commercial scale. Prof. A. L. Gibson, of the Ontario Agricultural College, then discussed "The Chemistry of Some Butter Defects," and enumerated various methods of overcoming these defects, but pointed out that in dairying, as in health, "prevention was better than cure." The close co-operation of the chemist and bacteriologist was absolutely essential, and it was deplorable that there were so few scientific workers in the Canadian dairy industries. The morning session ended with a paper on "The Corrosion of Containers by Canned Foods and Its Effects," by Messrs. H. W. Powell and E. W. McHenry, of the Research Laboratory of Dominion Canners, Ltd.

Mr. F. J. Hambly presided at the afternoon session of the Canadian Sections, and Mr. Alfred Burton, secretary of the General Council of the Canadian Sections, informed the members of the Annual Meeting of the Society in Liverpool. Dr. W. H. Hatcher then described recent work carried on in the laboratories of the McGill University, concerning the physical and chemical properties of hydrogen peroxide. The progress being made in the extension of the Department of Chemistry of the University of Western Ontario was outlined by Dr. J. A. Gunton. Mr. G. E. Condé, superintendent of the Flint Varnish and Colour Works of Canada, Ltd., Toronto, in a paper on "The Manufacture and Application of Nitrocellulose Lacquers and Enamels," described developments in the manufacture of these lacquers and finishes, and outlined various tests. Prof. L. F. Goodwin, of Queen's University, gave the final address on "Nitrogen Fixation Processes," in which he reviewed the developments that had occurred during the past twenty-five years, from the time that Sir William Crooks had startled the world with his famous warning as to the depletion of Chilean nitrate as a source of nitrogen. Prof. Goodwin illustrated his resumé with lantern slides showing plant practice in Scandinavia, Germany, France and England.

The Annual Dinner was held in the evening at the Cataraqui Golf Club, just beyond the confines of the city, and beautifully situated, overlooking the lake, where 100 guests were present, Mr. Alfred Burton acting as toastmaster. Following the toasts, the most westerly representative present, Prof. Shipley, and Mr. Dawson, representing the east, were called upon for a few remarks. Prof. Shipley regretted that on account of the distance it was almost impossible for Western Canada to have many representatives at the Annual Conventions, but that in all probability Western Canada would organise a convention of its own.

On the morning of Wednesday the annual meeting of the Canadian Institute of Chemistry was held, and, with Prof J. W. Shipley presiding, a series of papers was delivered in the afternoon. In the evening a public address was delivered by Mr. Horace Freeman on the "Application of Chemistry to the Natural Resources of Canada," a film being shown of calcium carbide manufacture at Shawinigan Falls.

The last two days of the Convention were spent in visiting points of interest about Kingston. After visiting the locomotive works the party went to the Royal Military College, where the laboratories were inspected. The visitors lunched with General Sir A. MacDonell, Commander of the College, and spent the afternoon and evening on the river going through the Thousand Islands. On Friday visits were made to the plants of the Canadian Industrial Alcohol Co., at Corbyville, and the Deloro Smelting and Refining Co., at Deloro, thus ending a most successful meeting.

CORRESPONDENCE

A POINT OF ORDER

Sir,—At the last meeting of the Chemical Society (this vol., p. 665), Prof. Ingold represented styrene by the formula $\overset{+}{\mathrm{Ph}}.\overset{-}{\mathrm{C}}\mathrm{H}:\overset{+}{\mathrm{C}}\mathrm{H_2}$ and diphenylethylene by the formula $\begin{matrix}\overset{+}{\mathrm{Ph}}\\ \overset{+}{\mathrm{Ph}}\end{matrix}\!\!>\overset{-}{\mathrm{C}}:\overset{+}{\mathrm{C}}\mathrm{H_2}$. I gathered that in these formulæ the plus and minus signs were being used in the ordinary way to represent electrical charges, *i.e.*, a deficit or a surplus of one electron. If, however, they are used in this sense, the formula for styrene is clearly that of a *univalent kation* like $\overset{+}{\mathrm{N}}\mathrm{H_4}$, and not of a neutral molecule, whilst the formula for diphenylethylene would represent a *bivalent kation* like $\overset{++}{\mathrm{Mg}}$ or $\overset{+}{\mathrm{N}}\mathrm{H_3.C_6H_4.}\overset{+}{\mathrm{N}}\mathrm{H_3}$. These curious and undesired results would be impossible in face of a strict adherence to the valuable rules that (*i*) *in any ionised bond the positive and negative charges of an electrovalence replace instead of supplementing a non-polar bond*, and (*ii*) *these charges must always be introduced in pairs, since the electron lost by one atom is always transferred to another*. If these rules are adopted, it is clear that in the case of styrene the ionisation of the double bonds of the aromatic nucleus would leave the phenyl-group as a whole *neutral*, although the carbon-atom next to the side chain may be either positively or negatively charged, since the nucleus of a substituted benzene can be polarised in two opposite ways.

These rules suggest further that an unsubstituted phenyl-group is not likely to be very efficient in determining the sign of the charges assumed by the various atoms of an associated conjugated system when activated, since the carbon atoms of the aromatic nucleus (unlike the metal in a radical such as $\overset{-}{\mathrm{O}}\overset{+}{\mathrm{N}}\mathrm{a}$) can adapt themselves to either polarity in the side-chain. One might, therefore, expect the phenyl-group to behave "amphoterically" (although perhaps with a definite preference for one of the two alternative forms) and to act differently in different compounds, or even in the same compound under the influence of different re-agents. I gather from Prof. Lapworth, as well as from Prof. Ingold, that this expectation is in agreement with the experimental facts. The amphoteric character of the phenyl radical is also indicated by the fact that Prof. Robinson has already used the same idea in connexion with the electrolytic dissociation of hexaphenylethane (or triphenylmethyl)

$$\mathrm{PH_3C.CPh_3 \rightleftharpoons Ph_3\overset{+}{C} + \dot{C}Ph_3}$$

where he regards the phenyl-groups as being oppositely polarised in the two ions.

There is no need for me to defend the theory of induced alternate polarities, which is quite secure in its Manchester stronghold. My own responsibility has been incurred in suggesting an electronic mechanism, which makes the phenomenon inevitable in conjugated systems undergoing chemical change, but has also the effect (fortunate or unfortunate) of limiting it to conjugated systems—except, perhaps, in those cases where a single bond can be ionised or activated in the same way as the double bonds of a conjugated chain. My present object is, therefore, merely to object "on a point of order" to the use of symbols in such a way that ions and molecules are not clearly distinguished from one another.—I am, Yours, etc., T. M. LOWRY

July 1, 1924

SYNTHETIC RESINS

Sir,—In your news of the French synthetic resin industry published in the current number of *Chemistry and Industry* (p. 694), I imagine you are reporting a too generous estimate of the production of artificial resin in France. I believe that M. Georges Kimpflin estimated the figure as 100 tons per month, reducing the amount reported in your news item to one-tenth. It would be distinctly encouraging to the synthetic resin industry if the production of resin in France and America alone, amounted to over 70,000 t. annually.

It is of interest, I think, that M. Kimpflin in his address also quoted the amount of the production of artificial resin in Germany as being 300 t per month. He does not appear to refer at all to British manufacture, evidently regarding this as insignificant. I suppose the British production can be reckoned in tens of tons per month and not hundreds. If this is correct its insignificance compared with that of other countries is a surprising fact and must be due either to lack of enterprise and development by the British manufacturer, compelling the British user to go abroad for supplies, or to a restricted demand owing to the lack of realisation by the possible consumer (of insulating material, varnish, etc.) of the profitable results to be obtained with the various classes of artificial resins.

The need, of course, exists—as, according to M. Kimpflin, it exists in France—for further and continued research on the subject in order to extend the knowledge of the scientific principles involved, and thus—and only thus—to establish a sound and lasting industry.—I am, Sir, etc.,

ALAN A. DRUMMOND

Iver, Bucks
July 5, 1924

PERSONAL AND OTHER ITEMS

Prof. J. C. McLennan, of the University of Toronto, has been elected president of the Royal Society of Canada.

Mr. T. Thorne Baker has been awarded a silver medal by the Royal Society of Arts for a paper read before the Society during the past session.

Mr. A. W. Nash, B.Sc., M.I.Mech.E., at present lecturer in oil mining in the University of Birmingham,

has been appointed professor of oil mining in the same University.

Mr. George Douglas has been elected chairman and Sir Thomas Robinson, M.P., vice-chairman, of the Bradford Dyers' Association.

Dr. W. Campbell has been appointed the first Howe professor of metallurgy at Columbia University. The new chair was established in memory of the late Prof. H. Marion Howe. Dr. Campbell was born at Gateshead-on-Tyne, England, in 1876, and took the D.Sc. of the University of Durham in 1905, having also studied at the Royal School of Mines and at Columbia University.

Mr. Francis P. Garvan, president of the Chemical Foundation, New York, has left for Europe.

Beit Memorial Fellowships

At the recent meeting of the trustees, it was stated that, during the past year, research work had been carried on by one Senior Fellow, one fourth year Fellow, and twenty Junior Fellows. The reports of the directors of the laboratories where the Fellows were engaged indicate that their work was satisfactory and that valuable additions to science may result from their researches. The Advisory Committee has recommended the renewal for another year of the Junior Fellowships that do not now expire. Amongst those elected to Fellowships are the following names, the proposed researches being also given: Dr. A. S. Parkes, researches on breeding and on the feeding of animals (work on the latter subject is now proceeding in collaboration with Prof. J. C. Drummond). Dr. H. Cohen, work on the chemical composition of cerebrospinal fluid and on the introduction into it of therapeutic substances and other chemical problems of the blood system. Miss Margaret A. Boas, B.Sc., research on vitamins, including the effect of ultra-violet radiation. Mr. H. F. Holden, M.A., study of the optically active substances, other than glucose, in normal and diabetic protein-free blood.

Ramsay Memorial Fellowships

The second dinner in honour of the Ramsay Memorial Fellowship Trustees and the Ramsay Memorial Fellows was held on July 4 at University College. The chair was taken by Sir Gregory Foster, the Provost of University College, and the memory of Sir William Ramsay was honoured at the instance of Prof. J. Norman Collie, the chairman of the advisory council.

Sir Hugh Bell, in proposing "The British Dominions and Foreign Countries Associated with the Ramsay Fellowship Trust," said one of the most remarkable things about the Ramsay Fellowships had been the ardent response which had been forthcoming from foreign countries, and in this respect they could be said to be more of a real and active league of nations than anything else in the world. The Japanese Ambassador, responding to the toast, said man was engaged in a perpetual struggle with nature in an endeavour to discover her secrets, and it was largely due to the work of comparatively unknown men that secrets were wrested from nature for the benefit of mankind. They did not know how much they owed to the work of those men.

Prof. F. G. Donnan proposed "The Ramsay Memorial Fellowship Trustees." Sir John Brunner, who replied, said the Government did not do much, and therefore it fell to private enterprise largely to endow research. His firm were very pleased indeed with the results which the funds they had provided had produced.

The Chairman proposed "The Ramsay Memorial Fellows," and Dr. R. Winstanley Lunt and Dr. H. Weiss replied. (*The Times.*)

Honours for Distinguished Chemists

At the annual Degree Day of the University of Birmingham on Saturday last the honorary degree of Doctor of Laws was conferred by the Chancellor (Viscount Cecil of Chelwood) upon Professor F. Gowland Hopkins, F.R.S., Professor of Biochemistry in the University of Cambridge and the discoverer of vitamins; and Professor Percy Faraday Frankland, F.R.S., Emeritus Professor of Chemistry in the University of Birmingham.

In presenting Professor Gowland Hopkins, the Principal of the Birmingham University (Mr. Grant Robertson) observed that biochemistry was one of the most recent of our sciences to define its boundaries, to differentiate its subject matter, and to devise its special technique and to claim for itself and by its functions its separate right to self-determination in the world of exact science, and that place in the sun which lavish endowment alone could make warm, successful and secure. Professor Hopkins had been happy in attracting the endowment to his University of Cambridge and in asserting the right of biochemistry to self-determination and to indisputable achievement. Even the oldest and most ignorant had heard of vitamins and that day they were able to honour the discoverer of vitamins. Professor Hopkins as Huxley Lecturer at the Birmingham University was able to prove that he could be an intellectual vitamin, supplying just that indefinable element of stimulus essential to intellectual health. But the Sir William Dunn Professor had done much more than discover vitamins. He had shown by his researches how biochemistry was the indispensable ally of medicine on the one side and of organic chemistry on the other and he had marked out for it a career with an assured future and from its devoted servants a certain treasury of help to life, truth and social progress.

In presenting Professor Frankland, Emeritus Professor of Chemistry in the Birmingham University, for the distinction, Mr. Grant Robertson said it seemed almost unnecessary to explain the reasons why the Council and Senate had wished to bring there from his Scottish fastness their former Professor and to confer that particular degree. The son of the late Sir Edward Frankland, F.R.S., himself a brilliant chemist and an accomplished scientist. Professor Frankland had made his mark by his contributions to stereo-chemistry, to the science

of fermentation, to bacteriology and biology, and in the application of bacteriology to air, water and earth. In the science of sanitation he had inherited and continued the work of his father. Those achievements were, indeed, contributions to civic civilisation. But to-day they were not thinking so much of his eminence as a scientist, as of his work in and for Birmingham University and Birmingham. He came to Birmingham in 1894, to be a professor in Mason College and after the University was founded in 1900 he remained for nineteen years as the head of the department of Chemistry which grew mightily under his vigorous and exacting administration. He had distinguished colleagues three of whom, Poynting in physics, Lapworth in geology, Adrian Brown in the science of fermentation had passed away; but they had inherited the fruits of their labours. Professor Frankland created their Honours School of Chemistry—the first of their Honour Schools of Science—and he set up and developed a notable department of research which had been of vital importance to the industries of the Midlands. To these achievements he added in the four years of war a continuous series of services which proved that British brains and British science were more than equal to the brains and science of our foes. They welcomed his return to the scene of his life's work and assured him that the legacy he bequeathed to his department was not buried and that their Faculty of Science was determined to maintain and to develop the tradition and the ideals which inspired his efforts.

GENERAL

Sesamum Crop of 1923-1924 in British India

From reports based on a memorandum dealing with the final estimates of the sesamum crop in British India, the total yield for the year 1923-24 is estimated at 431,000 tons, from an area of 5,018,000 acres. The quantity exported by sea from British India to foreign countries during the year was 9537 t., as against 36,436 t. in 1922—23—(*Ind. Tr. J.*, *Apr.* 24, 1924.)

The World Production of Zinc

In 1913 the total output of zinc in the world was 981,000 tons, a figure which fell to 445,000 t. in 1921, rising to 722,000 t. in 1922, and over 864,000 t. in 1923. Of the 1923 production the United States produced the largest quantity, namely 418,000 t., Belgium following with 138,000 t.

Synthetic Methyl Alcohol

It is announced that methyl alcohol is now being synthesised on a commercial scale from water gas. In presence of a catalyst (iron filings covered with potassium carbonate) and under a pressure of 150 atmospheres and at a temperature of 400–450° C., the carbon monoxide is converted into methylalcohol, formaldehyde being the bridge product. An oily liquid is said to be produced from which the alcohol is obtained by distillation. The residue contains napthenes resembling those present in certain petroleums.

REVIEWS

Briquetting. By A. L. Stillman, M.Sc. Pp. x + 466. Easton, Pa.: The Chemical Publishing Co., 1923. Price $6·0.

Although briquetting has been for many years practised on an extensive scale in all civilised countries there has, until the publication of this work, been only one authoritative book on the subject, that of Prof. Franke, translated from the German during the war by F. C. A. Lantsberry. It may be considered with some degree of truth that one of the reasons for this is that briquetting as usually practised has been anything but an exact science, and those engaged in the industry have not always been able to devote time and incur expense in collecting technical and commercial information.

The present volume is particularly welcome at a time when renewed attention is being given to the scientific and economical development of the world's fuel resources, and to the treatment of ores and waste materials. Although written largely from the American point of view, practically every aspect of the briquetting of materials both combustible and metallic is dealt with in a methodical manner. All general information is, as far as possible, put into classified tabular form convenient for reference. Detailed and illustrated descriptions of the plant and processes follow. An important chapter is that descriptive of the various types of briquette press and briquetting machinery, and special mention should be made of a very practical chapter on laboratory research in briquetting. This contains much sound advice, but the statement (p. 418) that a hand press always gives better results than are obtainable in actual practice is hardly correct, except possibly with pitch as a binder.

The chapter on binders is excellent, although not quite up to date. No doubt a subsequent edition will make some reference to recent developments in the use of cassava starch, seaweed, and the vegetable binders which are being successfully developed in South Africa and in this country. The absence of a reference to the admixture of pitch by means of spraying is also noticeable. It has long been almost an axiom in the patent fuel industry that pitch is the only satisfactory binding material, but the crisis in the price of pitch last year is likely to have far-reaching results, and there are indications that a duplex binder containing only 2 or 3 per cent. of pitch for waterproofing purposes is likely to prove more economical and satisfactory.

Mention should also have been made of Macnab's vibration method of pressing, of Sutcliffe and Evans' pure coal briquette process, and of the possibilities of briquetting with inferior binders prior to low-temperature carbonisation. Much more stress should also have been laid upon the importance of accurate and scientific grading of the material to be briquetted, this being particularly important when binders other than pitch are used. In the Colonies and many foreign countries coal or lignite deposits are often of such high volatile content that carbonisation either preceded or followed by briquetting is the economic solution, having regard to the fact that the principal

usage is mainly for the railways. For the latter, complete waterproofness is unnecessary, particularly as in tropical countries the trucks are usually of the box type.

Mr. Stillman has given us an excellently written and illustrated treatise, which can be confidently recommended as a reliable survey of the briquetting field.

C. J. GOODWIN

PULVERISED COAL SYSTEMS IN AMERICA. By LEONARD C. HARVEY. Fuel Research Board. Special Report No. 1. Third Edition. Pp. 131. H.M. Stationery Office. Price 5s

This is the third edition (Jan., 1924) of Mr. L. C. Harvey's well-known and detailed volume which has always been indispensable to the library of everyone interested, directly or indirectly, in the subject of pulverised fuel firing. The additions bring the extremely valuable bibliography, one of the best features of the publication, up to July 31, 1923, although so rapid is the progress of pulverised fuel that much new material has since become available.

Some later results obtained with pulverised fuel in malleable-iron melting furnaces are also given, although the primary objection to this method of firing in competition with ordinary coal, oil, and producer (or other) gas is the slagging trouble, that is the melting of the ash. It is, of course, in steam generation that pulverised fuel firing has made the most remarkable developments during the past three or four years, and the new edition gives a list of a number of boiler plants on the "Lopulco" system. This list is incomplete to-day and necessarily cannot include some of the more remarkable examples, such as the extensions of the Colfax Station of the Duquesne Light Co. of Pittsburg and the Gennevilliers Station (Paris) of the Detroit Edison Co., nor, of course, the British installations now in progress at St. Pancras and Willesden, and the recent orders of the Birmingham Corporation.

There are a number of points in the latest methods of pulverised fuel firing of particular interest to the chemist and the chemical engineer which Mr. Harvey does not perhaps bring out quite clearly. In the first place the new vertical gravity coal-drier, using only about 10 per cent. of the hot gases from the chimney base mixed with cold air to give an average temperature of about 215° F., is undoubtedly a great improvement on the various horizontal driers, and the total heat or power required for drying is now only equivalent to about 3 k.w. per ton of coal, that is, the power necessary for the circulating fan. Also it means that the latest practice is merely to dry the coal from the point of view of the added or "mechanical" moisture only, and a typical specification is to dry down from 10 per cent. to 4 per cent. moisture. Incidentally it is high time we had some clear understanding of the difference, from the point of view of phraseology, between the added or external moisture and the natural moisture of coal, together with the water given off by actual decomposition of the coal substance; the term "hygroscopic moisture" is a particularly stupid phrase.

Pulverised fuel firing represents a revolution in the combustion of solid material from several points of view. In the first place, the contact between the particles of the fuel and the air is so intimate that an excess of only about 20 per cent. of air over the theoretical is required for complete combustion, the very best practice with the latest type of mechanical stoking being about 40 per cent. excess, whilst ordinary methods of combustion represent, say, 75-200 per cent. more air than the theoretical passing through the furnace. In this connexion detailed tests at Lakeside showed 10·7 to 25·1 per cent. excess depending on the rating, so that, combined with the fact that the moisture in the coal is cut down to 4 per cent., it is easy to see one of the reasons of the intensely hot flame in the combustion chamber and also why slagging or the melting of the ash has always been a difficulty with pulverised fuel. Another point, which certainly ought to be emphasised, is that, for the first time with solid material, pulverised fuel enables us to regard a furnace merely from the point of view of the number of British thermal units of heat to be put into it. That is to say, under normal conditions, a very large water-tube boiler may require, say, 225,000,000 B.Th.U. per hour (about 10 t. of coal), and with pulverised fuel we simply add the right weight of coal calculated according to the heat value. That is, we do not need any longer to worry about all kinds of factors, such as volatile matter, resinous content, coking properties, sulphur, moisture, ash and melting point of the ash, but merely add the weight necessary to give the B.Th. units, whereas many of the above items might easily run a mechanical stoker to a standstill. Just in the same way if we want more evaporation, we add more B.Th. units in a given space of time in a way impossible with any ordinary method of firing. The only fuel with which there is difficulty is low volatile anthracite, and this can easily be remedied by adding a little high volatile material.

It should be noted, also, that the objections to pulverised fuel have long been due to the furnace, and the preparation, that is, crushing, drying and pulverising, is to-day comparatively a minor matter. The invention of the large volume combustion chamber with hollow air-cooled walls and the water screen are really more responsible for the great advance in pulverised fuel firing than Mr. Harvey seems to indicate.

DAVID BROWNLIE

RESINES ET TÉRÉBENTHINES LES INDUSTRIES DÉRIVÉES. By M. VEZES and G. DUPONT. Encyclopedie de Chimie Industrielle. Pp. 656. Paris: J. B. Baillière et Fils, 1924. Price, Paper 60 fr., Bound, 70 fr.

In the preface of the book the authors show that the output of the French Naval Stores Industry (turpentine and rosin) is 15 per cent. of the world's production compared with 75 per cent. from U.S.A., but France is easily first among the European producers. The

history of the development of the cultivation of *Pinus maritima* is admirably outlined, and tribute is paid to Haller, Béhal, Grignard, Barbier and the younger scientists, *e g.*, Darmois, Pariselle and Vavon for their endeavours to develop in France an industry in which the raw material is produced in the country. Part 1 of the treatise deals with balsams and resins; Part 2 deals with terebenthines (oleoresins) and forms more than half the contents of the book; Part 3 comprises an account of the rosin oil industry and the manufacture of other rosin products. The classification of the balsams and resins is the same as in Coffignier's "Les Vernis," and the copals, together with the natural and synthetic resins other than oleoresins, are only briefly described. In this section the references to the literature already published are not sufficiently up-to-date, and the work of investigators outside France has not received adequate attention. Nevertheless, in the preface the authors are careful to state that the work has no pretensions to be complete or to exhaust the vast subject which its title indicates. It is in Parts 2 and 3 that the interest of the reader will be centred. The authors show the superiority of cultivation and "gemmage" in the French industry, but at the same time they criticise the customs of the "*résiniers*," and appeal for a proper appreciation of factory requirements. They call attention to the defects in the present methods of treatment of the oleoresin in the French turpentine districts, and to the lack of adequate standards for some of the French products The extraction of turpentine in Russia, Spain and other countries is described in an effective manner The readers of Part 2 of the book will not fail to be impressed by the authoritative character of the information given. In Part 3 the development of the rosin oil industry is well discussed and the methods of manufacture and properties of a number of rosin products, *e.g.*, soaps, siccatives, rosin esters, printing inks, pitches and blacks, are concisely given with an adequate amount of detail. The authors consider that a description of the products from turpentine, viz., borneol, camphor terpineol etc, is worthy of a special volume The application of the knowledge of chemical composition to industrial processes is fully appreciated by the authors. The chemistry of the terpenes and abietic acid is well given, but the formula for retene on page 433 is incorrect, and the modification of Easterfield and Bagley's formula for abietic acid is not in keeping with the results of recent work by Ruzicka. The importance of investigations instituted in the faculty of Sciences of Bordeaux during the last twenty years must be acknowledged, and the results have proved to be of value to manufacturers in the south west and other regions of France and abroad

Considering the extent of the ground covered by the authors their treatment of the subject is very lucid. The book contains a fund of information on matters pertaining to resins, and is a valuable contribution to the literature on the subject written by experts with a profound knowledge of the Naval Stores Industry.

R. S. MORRELL

REPORT

SIXTIETH ANNUAL REPORTS ON ALKALI, ETC., WORKS, 1923. By the CHIEF INSPECTORS. Pp. 40. H.M. Stationery Office, 1924. Price 1s 6d.

No general revival of chemical industries has taken place during the year, though in the tinplate trade there has been exceptional activity. The superphosphate industry has been brought almost to a standstill by foreign competition. The number of registered works in England and Wales was 1219 and of separate processes 1995, being a decrease of 21 and 10 respectively on the previous year. Complaints against registered works have not been excessively numerous and usually related to short-lived escapes of fumes due to accidental occurrences. Advice has been given in cases of complaints of nuisance arising from certain non-registrable processes, such as petroleum distillation, the bleaching of wool by means of sulphur dioxide and from excessive smoke from coke ovens.

Alkali and Copper (*Wet Process*) *Works* —Work has been of a limited character due to the competition of synthetic hydrochloric acid and the increased use of sulphur in place of copper pyrites in the manufacture of sulphuric acid. Condensation of hydrochloric acid has been satisfactory at all works

Cement Works.—Chamber kilns are still much in favour, especially in the South of England and continue to hold their own. No advance has been made in the recovery of potash salts owing to the impossibility of competing with the natural product.

Smelting Works-- Progress in the collection of metallic oxides from chimney gases by means of cyclone dust-catchers is recorded An increased amount of sulphuric acid is being made by the calcination of zinc blende, notwithstanding the difficulty caused by the presence of lead in the Australian concentrates now chiefly used.

Sulphuric Acid Works. The employment of sulphur in place of pyrites and the use of mechanical sulphur burners is extending. During the year one more works has adopted electrostatic deposition of dust in connexion with a chamber plant. There has been no great demand for concentrated acid and there is now no valid reason for any nuisance caused by local fumes. The installation of scrubbers fed with soda solution in connexion with the exit gases from Grillo plants has led to good results, the total acidity being reduced to less than 1 gram of SO_3 per cubic foot and a high-strength bisulphite made.

Chemical Manure Works. -At such works as have been operating results have been satisfactory.

Sulphate of Ammonia and Gas-Liquor Works.—Reference is made to cases in which trouble has been caused by oxide purifiers having been too small or too few for their work or by leaky joints. Whilst the treatment of the effluent from the distillation of ammonia liquor made from horizontal retorts in dephenolating towers is satisfactory, this is not the case with vertical retort liquor. This contains polyhydric phenols which are not destroyed and also a notable quantity of thiocyanate and thiosulphate.

Ammonia plant effluent mixed with town sewage can, however, be dealt with by treatment on the land, if the proportion of effluent is small and reasonably constant. A detailed report of experimental work on this subject is given.

Chlorine Works. There has been more activity in the manufacture of chlorine products other than bleaching powder. A wide field for the use of liquid chlorine is opening up.

Muriatic Acid Works. Control in the synthetic process for the manufacture of the pure acid has been excellent. Fibre separation works have been rather more active. In tinplate flux works, where great activity has prevailed, the use of size in the pickling process has considerably extended.

Tar Works.—Complaint is made of the poor condition of pitch coolers at some works and of pitch being discharged at an excessive temperature. Tar distilled during the year amounted to 1,457,200 tons and pitch produced to 587,818 t.

Report on Scottish Works. During 1923 there were 161 registered works in Scotland, operating 303 scheduled processes. Production data include: Pyrites and spent oxide burned 104,613 t., phosphates and bones dissolved 54,144 t., ammonia made (as sulphate), 97,594 t., tar distilled 224,968 t., pitch produced 89,544 t. The last three items show considerable increases over 1922. Of the tar 90,000 t. was partially distilled to road tar.

An experiment is reported, in a sulphuric acid chamber plant, in feeding the second Gay-Lussac tower with a small quantity of water instead of a large volume of strong acid. The resulting exit gases were normally very low in acidity and the cost of pumping acid was reduced. In tar works trouble with pitch fumes has occurred in some cases. This has been avoided in one works by drawing the fumes by a fan through a closed range of pipes with condensation to oil. Two deaths occurred owing to a sudden rent in a charged tar still. The setting of the still adjacent was under repair and two men at work in the flues were caught and suffocated by the fire which broke out.

The technical side of the Report will be dealt with in a later issue of the Abstracts (B.) issued by the Bureau of Chemical Abstracts.

COMPANY NEWS

W. & T. AVERY, LTD.

A further dividend on the ordinary shares is recommended of 10 per cent., making 15s. per cent. for the year, less tax. The carry forward is £38,111 and £10,000 is placed to reserve.

DISTILLERS COMPANY

The report states that after providing for depreciation and payment of debenture interest the profit and loss account shows a balance for the year of £677,914, which with £107,545 brought forward makes available £787,459. There has been added to reserve fund £211,420, to fire insurance fund £5000, and to superannuation fund £25,000. The directors recommend a final dividend on the ordinary shares of 6 per cent., making 10 per cent., tax free, for the year, leaving £119,530 to be carried forward. The balance of profit for the previous year was £620,637, and £98,770 was brought forward. The reserve fund received £200,000, fire insurance £5060, and superannuation £30,000, while the ordinary dividend was also 10 per cent. During the past year the reserve fund was capitalised to the extent of £911,420. This fund, with the £211,420 added, now stands at £250,000, the fire insurance at £155,600 and superannuation and provident fund at £165,971.

MIDLAND BANK, LTD.

The directors announce an interim dividend for the half-year ended June 30 last at the rate of 18 per cent. per annum less income tax, payable on July 15. The dividend for the corresponding period of 1923 was at the same rate.

MOND NICKEL CO., LTD.

The profit and loss account for the year ended April 30 shows a net surplus of £276,458 (against £307,774 in the preceding year). The year's Preference dividend takes £175,000, and the dividend on the Ordinary shares absorbs £112,500. The latter dividend is equal to $12\frac{1}{2}$ per cent., less tax, and compares with 10 per cent., free of tax, for 1922-23. After allowing for directors' fees (£13,823), the balance to be carried forward is £40,403, as against £65,268 brought in.

BRITISH GLASS INDUSTRIES, LTD.

On June 4, the High Court of Justice (Chancery Division) confirmed the reduction of the capital of British Glass Industries from £5,000,000 to £2,255,218.

ENGLISH OILFIELDS, LTD.

The report for 1923 states that the policy of the reconstituted Board to exercise strict economy has been maintained. The directors have concluded, after wide consultation, that there is no reasonable prospect of commercial success in the production of oil from the company's properties. They have therefore decided to free the company at the earliest moment from the heavy and increasing rent obligations under their mining leases. Meanwhile proposals for the utilisation of the costly plant at Setch or for its realisation are under consideration. Proposals for securing valuable interests for the company in other directions are under examination, and something has already been accomplished on favourable terms. The directors' policy is, at the proper moment, to submit proposals for writing down the capital drastically, so that it may be represented by tangible assets, and to build up a new business as the only alternative to a liquidation which would yield little or nothing for the shareholders. The balance-sheet for 1923 shows that with development and administrative expenses amounting to £21,158 during the year this liability now stands at £102,120

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech.	£23 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	£45 per ton.
Powder	£47 per ton.
Acid Hydrochloric	3s. 6d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers' works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Methylated Spirit 64 o.p.—	
Industrial	3s. 1d.—3s. 5d. per gallon, according to quantity.
Mineralised	4s. 2d.—4s. 6d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	5¾d. per lb.
Potass. Chlorate	3d.—4d. per lb
Salammoniac	£32 per ton d/d.
Salt Cake	£3 10s. per ton d/d.
Soda Caustic, solid	Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton, carr. paid.
Sod. Bichromate	4½d. per lb.
Sod. Bisulphite Powder 60/62%	£18—£19 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £14 10s. per ton d/d.
Sod. Sulphide cryst.	£9 per ton d/d.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	5¾d.—1s. 4d. per lb., according to quality.
Crimson	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 11d. per lb.
Barytes	£3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide	3s. 9d. per lb.
Carbon Bisulphide	£24—£26 per ton according to quantity.
Carbon Black	7d. per lb. ex wharf. Dearer.
Carbon Tetrachloride	£56 per ton, drums free.
Chromium Oxide, green	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	45s. per cwt., barrels free.
Lead Hyposulphite	7½d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£15 10s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Sulphur Chloride	3d. per lb., carboys extra.
Thiocarbanilide	2s. 6d. per lb.
Vermilion, pale or deep	4s. 10d. per lb.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£14 10s. per ton d/d. Demand active.
Grey	£19—£20 per ton. Fair demand.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 per ton, according to grade and locality. Demand below normal.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. „ „ 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 7d. per gall. Unrefined.
Wood Naphtha—	
Miscible	5s. per gall. 60% O.P. Market dull.
Solvent	5s. 6d. per gall. 40% O.P. Fairly good demand.
Wood Tar	£5 per ton.
Brown Sugar of Lead	£46 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	6½d.—6¾d. per lb. Better inquiry.
Crude 60's	1s. 9d. per gall. Market flat. Only odd lots being offered.
Acid Cresylic, 97/99	2s 1d.—2s. 2d. per gall. Demand still good. Market firm.
Pale 95%	1s. 10d.—1s. 11d. per gall. Steady demand.
Dark	1s. 10d.—1s. 11d. per gall. Steady business.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	9½d. per gall. Very quiet.
Unstrained	8½d.—9d. per gall.
Benzole—	
Crude 65's	10½d.—1s. per gall. ex works in tank wagons.
Standard Motor	1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure	1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.
Toluole—90%	1s. 5½d. per gall.
Pure	1s. 10d.—2s. per gall.
Xylol coml.	2s. 3d. per gall.
Pure	3s. 3d. per gall.

Creosote—	
Cresylic 20/24%	9d.—9½d. per gall. Few inquiries.
Middle Oil / Heavy / Standard Specification	6d.—6½d. per gall according to grade and district. Market weaker.
Naphtha—	
Solvent 90/160	1s. 3d.—1s. 5d. Demand declining.
Solvent 90/190	1s. 2d.—1s. 4d. Fair business, passing.
Naphthalene Crude—	
Drained Creosote Salts	£6—£6 10s. Demand falling off.
Whizzed or hot pressed	£9 per ton. Little business.
Naphthalene—	
Crystals and Flaked	£16—£17 per ton.
Pitch, medium soft	57s. 6d.—60s. per ton f.a.s. for next season.
Pyridine 90/160	20s.—21s. per gall. Market less firm.
Heavy	12s.—12s. 6d. Little business.

INTERMEDIATES AND DYES

There has been an appreciable increase in dye-stuffs business during the past week. Prices remain constant.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H	4s. 3d. per lb. 100% basis d/d.
Acid Naphthionic	2s. 4d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 1½d. per lb. Steady demand.
Acid Sulphanilic	9½d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	7¾d.—8½d. per lb. naked at works.
Aniline Salts	7¾d.—9d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 19/31° C.	1½d. per lb. Demand steady.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline	3s. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£75 per ton.
Diethylaniline	4s. 9d. per lb. d/d., packages extra, returnable
Dimethylaniline	2s. 4d. per lb. d/d. Drums extra.
Dinitrobenzene	9d. per lb. naked at works.
Dinitrochlorbenzol	£84 10s. per ton d/d.
Dinitrotoluene—48/50° C.	8d.—9d. per lb. naked at works.
66/68° C.	1s. 2d. per lb. naked at works.
Diphenylamine	3s. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 4½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 1d. per lb. d/d.
Nitrobenzene	5½d.—5¾d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	11¾d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis
m-Phenylene Diamine	4s. 2d. per lb. d/d.
p-Phenylene Diamine	10s. 3d. per lb. 100% basis d/d.
R. Salt	2s. 6d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 5d. per lb. 100% basis d/d.
o-Toluidine	8½d. per lb.
p-Toluidine	3s. 6d. per lb. naked at works.
m-Toluylene Diamine	4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The demand for pharmaceutical chemicals is better for export to the British Dominions than for the Home trade.

Acid, Acetic 80% B.P.	£47 per ton.
Acid, Acetyl Salicylic	3s. 2d.—3s. 3d. per lb. Better demand.
Acid, Benzoic B.P.	3s. 6d. per lb. Larger supplies available. Market easier.
Acid, Boric B.P.	Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	19s.—21s. per lb.
Acid, Citric	1s. 6¾d. per lb., less 5% for ton lots. Market extremely firm. Upward tendency.
Acid, Gallic	3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst.	7s. per lb. for 1 cwt. lots. Market firm; increasing demand.
Acid, Salicylic	Prices quoted from 2s. per lb. down to 1s. 7d. for ton lots. Market still weak. Keen competition and smaller demand.
Acid, Tannic B.P.	3s. per lb. Market quiet.
Acid, Tartaric	1s. 1¾d.—1s. 2d. per lb. less 5%. Better tone but not yet very active. Cheap offers of second hand parcels of foreign acid. Higher prices expected in view of firmness of raw materials.
Amidol	9s. per lb. d/d.
Acetanilide	2s. 3d. per lb. for quantity. Demand slow. Prices shaded to secure large orders.
Amidopyrin	13s. 3d. per lb. Neglected. Stocks low.
Ammon. Benzoate	3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	12s. 6d. per oz. for English make.
Barbitone	15s. per lb. Quiet market.
Benzonaphthol	6s. per lb. Small inquiry.
Bismuth Salts	A steady market. Prices according to quantity:
Bismuth Carbonate	12s. 9d.—14s. 9d. per lb.
,, Citrate	11s. 1d.—13s. 4d. ,,
,, Salicylate	10s. 2d.—12s. 2d. ,,
,, Subnitrate	10s. 9d.—12s. 9d. ,,
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides—	Market firm.
Potassium	11d. per lb.
Sodium	1s. ,,
Ammonium	1s. 1d. per lb.
Calcium Lactate	Demand active. Good English make can be had from 1s. 7d. to 2s. 6d. per lb.
Chloral Hydrate	3s. 7d.—3s. 9d. per lb., duty paid.
Chloroform	2s. per lb. for cwt. lots. Very steady
Creosote Carbonate	6s. 6d. per lb. Little demand.
Formaldehyde	£55 per ton, *ex* works. English make.
Glycerophosphates—	Fair business passing
Calcium, soluble and citrate free	7s. per lb.
Iron	8s. 9d. per lb.
Magnesium	9s. per lb.
Potassium, 50%	3s. 6d. per lb.
Sodium, 50%	2s. 6d. ,,

Guaiacol Carbonate	11s. per lb. for cwt. lots. Slightly cheaper.
Hexamine	3s. 6d. per lb. for English make. Market quiet and steady.
Homatropine Hydrobromide	30s. per oz.
Hydrastine hydrochlor	English make offered at 120s. per oz.
Hydroquinone	4s. 3d. per lb. in cwt. lots. Foreign make.
Hypophosphites—	
Calcium	3s. 6d. per lb., for 28-lb. lots.
Potassium	4s. 1d. per lb.
Sodium	4s. ,,
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 5d. per lb., according to quantity.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£75 per ton, less 2½%.
Heavy Commercial	£26 per ton, less 2½%.
Heavy Pure	2s.—2s. 2d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	52s. 6d. per lb. Weaker.
Synthetic	26s.—35s. per lb., according to quantity. English make. Strong demand.
Mercurials	Market firm.
Red oxide	5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	3s. 6d.—3s. 7d. ,,
White precip.	4s. 7d.—4s. 8d. ,,
Calomel	3s. 11d.—4s. ,,
Methyl Salicylate	2s.—2s. 3d. per lb. for carboys. Not much demand. Holders would accept 1s 11d. for ton lots.
Methyl Sulphonal	26s. per lb.
Metol	11s. per lb. British make.
Morphine and Salts	Reduced by 1s. to 1s 3d. per oz.
Paraformaldehyde	3s. per lb.
Paraldehyde	1s. 6d. per lb. in free bottles and cases, according to holder and quantity. Firmer.
Phenacetin	6s. per lb. Ample stocks available.
Phenazone	7s. 3d. 7s. 6d. per lb. Quiet.
Phenolphthalein	6s. 6d. per lb Easier with supplies more plentiful
Potass. Bitartrate—99/100% (Cream of Tartar)	88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate	1s. 10d —2s. 2d. per lb
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Metabisulphite	7½d. per lb., 1-cwt. kegs included.
Quinine Sulphate	2s. 3d. per oz., in 100 oz. tins. Very heavy demand.
Resorcin	5s. 6d. per lb. Sales slow.
Saccharin	63s. per lb., in 50-lb. lots.
Salol	3s. 6d.—3s. 11d per lb. Easier in sympathy with other salicylates.
Silver proteinate	9s. 6d. per lb.
Sod. Benzoate, B.P.	2s. 9d. per lb. In quantity for British product.
Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity. Firm in common with other citrates.
Sod. Hyposulphite—	
Photographic	£13—£15 per ton, according to quantity, d/d. consignee's station in 1 cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	75s.—82s. 6d. per cwt., according to quantity. Market quiet.
Sod. Salicylate	Market more active. Powder 2s. 2d.—2s. 6d. per lb. Crystal at 2s. 5d.—2s. 8d per lb. Flake 2s. 9d.—2s. 10d. per lb.
Sod. Sulphide—	
Pure recryst.	10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Thymol	Very scarce indeed.

PERFUMERY CHEMICALS

Acetophenone	12s. 6d. per lb.
Aubepine	14s. 6d. ,,
Amyl Acetate	2s. 9d. ,,
Amyl Butyrate	6s. 9d. ,,
Amyl Salicylate	3s. 3d. ,,
Anethol (M.P. 21/22° C.)	4s. 6d. ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 10½d. ,,
Benzyl Alcohol free from Chlorine	2s. 10½d. ,,
Benzaldehyde free from Chlorine	3s. 6d. ,,
Benzyl Benzoate	3s. 6d. ,,
Cinnamic Aldehyde Natural	15s. 6d. ,,
Coumarin	20s. ,,
Citronellol	16s. ,,
Citral	10s. ,,
Ethyl Cinnamate	15s. ,,
Ethyl Phthalate	3s. 3d. ,,
Eugenol	10s. 6d. ,,
Geraniol (Palmarosa)	35s. ,,
Geraniol	11s.—18s. 6d. per lb.
Heliotropine	7s. per lb.
Iso Eugenol	15s. 9d. ,,
Linalol ex Bois de Rose	26s. ,,
Linalyl Acetate	26s. ,,
Methyl Anthranilate	9s. 6d. ,,
Methyl Benzoate	6s. ,,
Musk Ambrette	45s. ,,
Musk Xylol	16s. 6d. ,,
Nerolin	4s. 9d. ,,
Phenyl Ethyl Acetate	12s. 6d. ,,
Phenyl Ethyl Alcohol	16s. ,,
Rhodinol	57s. 6d. ,,
Safrol	1s. 10d. ,,
Terpineol	2s. 4d. ,,
Vanillin	24s.—24s. 9d. per lb. Price reduced. Demand steady.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	15s. 6d. per lb.
Anise Oil	2s. 8d. per lb.
Bergamot Oil	19s. 6d. per lb.
Bourbon Geranium Oil	30s. 6d. ,,
Camphor Oil	75s. per cwt.
Cananga Oil Java	10s. 6d. per lb.
Cinnamon Oil, Leaf	6½d. per oz.
Cassia Oil, 80/85%	8s. 9d. per lb.

Citronella Oil—		
Java 85/90% ..	.. 6s. per lb.	
Ceylon	.. 3s. 9d. per lb.	
Clove Oil	. 7s. per lb.	Cheaper
Eucalyptus Oil 70/75%..	2s. per lb.	Cheaper
Lavender Oil—		
French 38/40% Esters	29s. per lb.	Dearer
Lemon Oil ..	.. 3s. 2d. per lb.	
Lemongrass Oil	.. 3d. per oz.	
Orange Oil, Sweet	.. 13s. 3d. per lb.	Cheaper.
Otto of Rose Oil—		
Bulgarian ..	.. 27s. 6d. per oz.	
Anatolian .	.. 23s. 6d. per oz.	
Palma Rosa Oil ..	.. 19s. per lb.	
Peppermint Oil—		
Wayne County	.. 20s. 9d. per lb.	
Japanese ..	. 14s. 3d. per lb.	Cheaper.
Petitgrain Oil ..	.. 10s. per lb.	
Sandal Wood Oil—		
Mysore	.. 26s. 6d. per lb.	
Australian ..	.. 21s. per lb.	

PATENT LIST

The dates given in this list are, in the case of Applications for Patents, those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition not later than Sept. 2nd; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C., on July 17th.

I.—Applications

Badder. Evaporating and drying colloidal materials from solutions. 15,471. June 27.

Calder and Palmer. 15,261. See II.

Nathyan. Obtaining solid matter from a solution, suspension or emulsion. 15,160. June 23. (Ger., 22.6.23.)

Wauthier. Pulverizer. 15,124. June 23. (Belgium, 21.6.23.)

I.—Complete Specifications Accepted

7828 (1923). Deschamps. Facilitating physical or chemical reactions. (197,374.)

11,268 (1923). Brutzkus. Effecting chemical reactions in the interior of compressors. (217,717.)

32,188. Linden. Separating and recovering liquids and solids of different densities. (217,851.)

II.—Applications

Calder and Palmer. Scrubbers for scrubbing gases etc. 15,261. June 24.

Carpmael (Chemische Fabriken vorm. Weiler-ter Meer). Process for obtaining gases rich in ethylene. 15,436. June 26.

Chadburn. 15,324. See XII.

Koppers Co. Testing coal etc. 15,545. June 27. (U.S., 12.9.23.)

Rude. Gasification of fuel and production of gas. 15,497. June 27.

Rudeman. Manufacture of peat briquettes. 15,318. June 25.

Schwalbe. Wet carbonisation of wood etc. 15,252. June 24. (Ger., 25.6.23.)

Smith. Gas-producers. 15,299. June 25.

II.—Complete Specifications Accepted

34,628 (1922). Hackford. Production of oil gas. (217,613.)

7221 (1923). Becker. Coking retort ovens. (205,460.)

7836 (1923). Duffield. Apparatus for producing gas from powdered carbonaceous matter. (217,645.)

IV.—Applications

Akt.-Ges. für Anilin-Fabrikation. Manufacture of dyestuffs. 15,169. June 23. (Ger., 23.6.23.)

Ellis (Haeffely). Manufacture of dyes for vegetable fibres. 15,529. June 27.

IV.—Complete Specifications Accepted

11,900 (1923). Ransford (Cassella und Co.). Manufacture of alkyloxyacridines. (217,715.)

14,671 (1923). Bloxam (Durand et Huguenin Soc. Anon.). Manufacture of chlorinated amines. (217,753.)

19,837 (1923). Farbenfabr. vorm. F. Bayer u. Co. Manufacture of indigoid dyestuffs. (205,790.)

V.—Applications

Higgins. Preparation of cellulose fibres etc. from waste. 15,069. June 23.

Vains. Continuous chlorination of cellulosic materials. 15,600. June 28.

V.—Complete Specification Accepted

2699 (1924). Alsa Soc. Anon. Manufacture of glossy and hollow artificial threads. (214,497.)

VI.—Applications

Alcock, Ryley, and British Celanese, Ltd. Solutions, compositions, etc. for textiles etc. 15,510, 15,511. June 27.

Bonnet Ainé et ses Fils, Veuve. Machine for mercerising etc. skeins of thread. 15,591. June 28.

Durand et Huguenin Soc. Anon. Process of dyeing and printing textiles etc. 15,539. June 27. (Ger., 2.7.23.)

Green. Dyeing and printing. 15,374. June 26.

Poulson. Desizing, washing, and bleaching fabrics etc. 15,570. June 28.

Schlumpf. Dyeing and washing textile material. 15,278. June 24. (Switz., 29.6.23.)

Schlumpf. Machine for treating yarns in hanks with liquid. 15,279, 15,280. June 24. (Switz., 1.7.23, and 25.9.23.)

VI.—Complete Specification Accepted

15,002 (1923). Mitchell and Wordsworth. Dyeing and like machines. (217,758.)

VII.—Applications

Finlayson, Smith, and Woodall-Duckham, Ltd. Manufacture of suspensions of iron compounds. 15,267. June 24.

Shimadzu. Process of manufacturing lead oxide. 15,421. June 26.

Vains. Continuous manufacture of hydrate of chlorine. 15,599. June 28.

VII.—Complete Specifications Accepted

34,479 (1922). South Metropolitan Gas Co., Parrish, and Wright. Distillation of ammoniacal liquors. (217,611.)

9478. Aus. and Chem. Werke vorm. Auerges. Regenerating alkaline liquors. (217,685.)

VIII.—Complete Specification Accepted

9602 (1924). British Thomson-Houston Co. Quartz working. (214,630.)

IX.—Applications

Bremner. Cement manufacture. 15,350. June 25.

Marks (Polysius). Manufacture of artificial stone. 15,273. June 24.

IX.—Complete Specification Accepted

7251 (1923). Marks (Master Builders Co.). Colouring mortars and concretes. (217,633.)

X.—Applications

Breitenbach. Metallurgical furnaces. 15,330. June 2[illegible]

Edwards. Manufacture of iron or steel alloys. 15,266. June 24.

Lockwood. Concentration or separation of minerals. 15,327. June 2[illegible]

Reid. Reduction and alloying of metals. 15,268. June 24.

Soc. Anon. de Commentry-Fourchambault et Decazeville. Treatment of ores in blast furnaces. 15,343. June 2[illegible] (Fr., 3.7.23.)

XI.—Applications

Dutt. Electrolytic cells. 15,499. June 27.

Silumminite Insulator Co., Ltd., and Wythes. Electric insulating-materials etc. 15,514. June 27.

XII.—Application

Chadburn. Purification of oils. 15,324. June 25.

XIII.—Complete Specification Accepted

4691 (1923). Pollak. Manufacture of condensation products from formaldehyde and urea or thiourea and its derivatives (193,423).

XIV.—Complete Specification Accepted

34,613 (1922). Pratt. Aqueous dispersion of rubber, balata, or gutta-percha. (217,612.)

XV.—Applications

Akt.-Ges. fur Anilin-Fabrikation. Manufacture of tanning-materials. 15,540. June 27. (Ger., 29.6.23.)

Bechhold. Manufacture of glue etc. 15,410. June 26.

Cutter, Drew, and Duncalfe. Manufacture of gelatin from bone etc. 15,226. June 24.

XVII.—Complete Specification Accepted

16,782 (1923). Ling and Nanji. Treating starch for the production of maltose and other substances. (217,770.)

XVIII.—Applications

Aktiebolaget Separator. Method of making wort. 15,232. June 24. (Sweden, 5.7.23.)

Munton and Baker (Bedford), Ltd., and Reffell. Extraction of malt. 15,331. June 25.

XIX.—Applications

Akt.-Ges. fur Anilin-Fabrikation. Fungicides. 15,204. June 24. (Ger., 25.6.23.)

Jameson, Wilson, and Taylor. Pectin products. 15,601. June 28.

XIX.—Complete Specification Accepted

7592 (1923). Parker, and Co-operative Wholesale Society, Ltd. Pasteurisation of milk. (217,641.)

XX.—Applications

Carpmael (Chemische Fabriken vorm. Weiler Ter Meer). 15,436. See II.

Jena. Recovery of transformed healing and strengthening media. 15,270. June 24. (Ger., 26.6.23.)

Marks (Carbide and Carbon Chemicals Corporation). Process of combining ethylene with sulphuric acid. 15,155. June 26.

Ransford (Cassella and Co.). Production of arsinic acids. 15,260. June 21.

Ransford (Cassella and Co.). Production of arseno compounds. 15,528. June 27.

Wade (Karpen and Bros.). Manufacture of hexamethylenetetramine. 15,253. June 21.

XX.—Complete Specification Accepted

14,671 (1923). Bloxam (Durand et Huguenin Soc. Anon.). See IV.

XXI.—Application

Baker. Preparation of chemical substances for use in radiography. 15,130. June 23.

XXI.—Complete Specification Accepted

13,919 (1923). Allott, and Allott, Jones and Co., Ltd. Photographic printing-processes. (217,741.)

XXII.—Complete Specifications Accepted

34,738 (1922). Nolan, Clapham, and Nobel's Explosives Co., Ltd. Production of tetryl and ethyl tetryl. (217,614.)

7879 (1923). Etabl. Davey, Bickford, Smith et Cie. Explosives. (196,593.)

25,484 (1923). De Wendel et Cie. Preparation of explosive charges containing liquid air or oxygen. (217,169.)

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35 Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number: *Australia*: Hardware, machinery, engineers' requisites (The Official Secretary, Commercial Bureau, Australia House, Strand, London, W.C. 2. Ref. No. 412/7/1/1/254); *Australia (New South Wales)*: Sulphuric acid, carbonate of soda (The Agent-General for New South Wales, Australia House, Strand, W.C. 2. Ref. No. 356/5); *British India*: Steel, brass (The Directors of the Madras and South Maharatta Railway Company, Ltd., 25, Buckingham Palace Road, Westminster, London, S.W. 1); Iron, porcelain, aluminium (The Director-General, India Store Department, No. 10, Belvedere Road, Lambeth, London, S.E. 1). *Brazil*: leather, paper, (29); *Italy*. Hides, varnish, metal (9); *Latvia*: Agricultural instruments, (10); *Netherlands*: Silk (11); Surgical supplies (12); White lead, red lead, and zinc white (14); *Smyrna*: Ironmongery, metal (25); *South Africa*: Steel, A.X./1090); *Spain*: Varnish gums (20); Hardware, optical supplies (21); Machinery, photographic supplies (22), *Uruguay*: Paint, paper (35), Rubber insulated cords (B.X./1056); *Yugoslavia*: Tin (18).

Dyestuffs Production in the United States

The final report of the United States Tariff Commission places the output of dyestuffs in 1923 at 93,500,000 pounds, or 1,500,000 pounds more than was shown on the preliminary report issued two months ago. The value of the dyes was approximately \$51,050,000. Total sales are reported as 6,000,000 or 7,000,000 pounds less than production, indicating a normal stock on hand at the close of the year. There was an increase in production of nearly 4 per cent over 1922, a record production, exceeding largely that of 1920, a year in which the largest recorded output was attained.

Dyestuffs (Import Regulation) Act, 1920

The following statement relating to applications for licences under the Dyestuffs (Import Regulation) Act, 1920, made during June has been furnished to the Board of Trade by the Dyestuffs Advisory Licensing Committee. The total number of applications received during the month was 411, of which 316 were from merchants or importers. To these should be added 9 cases outstanding on June 2, making a total for the month of 420. These were dealt with as follows:—Granted—296 (of which 278 were dealt with within 7 days of receipt). Referred to British makers of similar products—65 (of which 54 were dealt with within 7 days of receipt). Referred to Reparation Supplies available—24 (all dealt with within 2 days of receipt). Outstanding on June 30, 1924—35. Of the total of 420 applications received, 356 or 85 per cent. were dealt with within 7 days of receipt.

PUBLICATIONS RECEIVED

WHERE TO BUY EVERYTHING CHEMICAL, 1924 EXPORT EDITION. Pp. 227. London: S. Davis and Co., 1924.

CATALOGUE OF LEWIS'S MEDICAL AND SCIENTIFIC CIRCULATING LIBRARY, including a classified index of subjects. Supplement, 1921-23. Pp. 84. London: Lewis's Library, 1924. Price 1s.

APPLIED CHEMISTRY. By I. D. Garard. Pp. vii+196. New York and London: The Macmillan Company, 1924. Price 15s.

REPORT ON THE ECONOMIC, FINANCIAL AND INDUSTRIAL CONDITIONS OF FINLAND DATED MARCH, 1924. By C. H. Mackie. Department of the Overseas Trade. Pp. 68. H.M. Stationery Office, 1924. Price 2s.

REPORT ON THE FINANCIAL, COMMERCIAL AND ECONOMIC CONDITIONS IN ROUMANIA, DATED MARCH, 1924. By A. Adams. Department of Overseas Trade. Pp. 66. H.M. Stationery Office, 1924. Price 2s.

REPORT ON THE COMPOSITION OF COMMONER BRITISH WINES AND CORDIALS (ALCOHOLIC AND NON-ALCOHOLIC). By G. C. Hancock, C.B.E., M.R.C.S., L.R.C.P., together with Report by the Government Chemist on the Examination of Samples. Reports on Public Health and Medical Subjects, No. 24. Pp. 58. H.M. Stationery Office, 1924. Price 1s. 6d. net.

PUBLICATIONS OF THE DEPARTMENT OF THE INTERIOR, Bureau of Mines, Washington: Government Printing Office, 1923-4:—

ANALYSES OF SAMPLES OF DELIVERED COAL, collected from July 1, 1915, to January 1, 1922, with a chapter on The Tidewater Pool Classifications. By N. H. Snyder. Bulletin 230. Pp. iv+174. 1923. Price 20 cents.

ACCIDENTS AT METALLURGICAL WORKS IN THE UNITED STATES DURING THE CALENDAR YEAR 1922. By W. W. Adams. Technical Paper 350. Pp. 31. 1923. Price 5 cents.

METAL-MINE ACCIDENTS IN THE UNITED STATES DURING THE CALENDAR YEAR 1922. By W. W. Adams. Pp. v+72. 1924. Price 10 cents.

PUBLICATIONS OF THE DEPARTMENT OF COMMERCE, Bureau of Standards, 1924. Washington: Government Printing Office:—

A NEW ELECTRICAL TELEMETER. By B. McCollum and O. S. Peters. Pp. 737—777. Technological Papers of the Bureau, No. 247. (Part of Vol. 17.) Price 15 cents.

LEGAL WEIGHTS (IN POUNDS) PER BUSHEL OF VARIOUS COMMODITIES. Circular of the Bureau, No. 10. Pp. 17. Price 5 cents.

PUBLICATIONS OF THE KENTUCKY AGRICULTURAL EXPERIMENTAL STATION. Lexington, Ky., 1923:—

STUDIES ON DAIRY CATTLE II. MILK PRODUCTION. No. 248. Pp. 20.

CALCIUM METABOLISM IN THE LAYING HEN. No. 250. Pp. 34.

A LIST OF THE BOOKS, BULLETINS, JOURNAL CONTRIBUTIONS, AND PATENTS BY MEMBERS OF MELLON INSTITUTE OF INDUSTRIAL RESEARCH DURING THE CALENDAR YEAR 1923. Bibliographic Series, Second Supplement to Bulletin No. 1. Pittsburgh, 1924.

JAHRBUCH DER ORGANISCHEN CHEMIE. By Prof. J. Schmidt. X. Jahrgang: Die Forschungsergebnisse und Fortschritte im Jahre, 1923. Pp. xvi+284. Stuttgart: Wissenschaftliche Verlagsgesellschaft m.b.H., 1924. Price, bound, 18 goldmarks; paper, 15·50 gm.

KURZES LEHRBUCH DER CHEMIE. By Werner Mecklenburg. Second edition. Pp. xvi+793. Braunschweig: F. Vieweg and Sohn Akt.-Ges., 1924. Price, paper 20 M., bound 23 M.

New Books.—Messrs. Longmans, Green and Co. announce that the following books are in the press or nearly ready: "The Simple Carbohydrates and the Glucosides," by Dr. E. F. Armstrong, F.R.S. (new edition); "The History of Bleaching," by S. H. Higgins, M.Sc.; "Metallurgy," by E. L. Rhead (new, enlarged edition); "Applied Elasticity," by Dr. J. Prescott; and "Mathematics for Technical Students," by E. R. Verity.

JOURNAL of THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council of Pure and Applied Chemistry

which consists of Representatives from

The Chemical Society, the Society of Chemical Industry, the Association of British Chemical Manufacturers, the Institute of Chemistry, the Society of Public Analysts, the Faraday Society, the Institute of Brewing, the Society of Dyers and Colourists, the Society of Glass Technology, the Iron and Steel Institute, the Ceramic Society, the Institution of Gas Engineers, the Society of Leather Trade Chemists, the Royal Photographic Society, the Mineralogical Society, the Biochemical Society, the Institute of Metals, and the Royal Agricultural Society.

VOL. 43 NEW SERIES — LONDON, JULY 18, 1924 — NO. 29

EDITORIAL

THE Society of Chemical Industry has held its carnival; a round of banquets and lavish hospitality, interrupted only by a business meeting lasting a couple of hours and by some capital papers making a total of about equal duration. Nearly five hundred members, wives, daughters and friends, took some part in the Annual Meeting; it was consequently the largest that has been held, one of the most interesting, one of the most important, probably the best organised, one of the busiest and, for those who attempted every item on the programme, one of the most fatiguing. The weather was excellent though inclined at times to be so hot as to make one lazy; everything went off without a hitch, the speeches were short, sharp and to the point, some of them distinguished by considerable humour. Liverpool has magnificent buildings, good cooks, attentive butlers, generous hosts, enthusiastic presidents, assiduous secretaries and grateful guests. After a sumptuous lunch, a visit to a works, an equally sumptuous dinner, a few good speeches made to an audience surrounded by a somewhat ethereal or ethylic atmosphere we returned, some late at night, some early in the morning, to that brief interval between days which has for many centuries sufficed to content the Britons; *Minima contenos nocte Britannos*, from which it appears we had this reputation at least as early as the days of Juvenal. Even when we reached our hotel we stayed awhile gossiping or in mutual accusation spent the fruitless hours, unwilling to retire though weary. We complain of these late hours, but we enjoy them and in our secret hearts it is of our faults we are proud. The remedy is simple but we refuse to take it.

> All covet life; yet call it pain:
> All feel the ill, yet shun the cure:
> Can sense this paradox endure?
> Resolve me, Cambray, or Fontaine

* * *

Viscount Leverhulme is, as we all know, a very remarkable man but his Messel Lecture was a revelation to the majority of us. It was far and away the most important and interesting feature of the meeting and it deserves to be read and pondered by a larger circle than the members of the Society of Chemical Industry. It was a bold thing for any man except a philosopher or student of ethics by profession, to address a body of industrial chemists in Liverpool in the year 1924 on the principles of religion as applied to the works and the laboratory. These principles are not the topics to which we are accustomed: scientific people have been too apt to consider a number of religious principles, especially the dogmatic ones, as not so verified by experimental evidence as the chemical and physical truths which they hear or propound in lecture theatres. And here comes a hard-headed manufacturer, hard-headed enough to make what is reputed to be a comfortable fortune in a difficult period of our history, and tells us studious people his views on the faiths which govern religious and scientific people respectively. And he tells us these in an interesting way and proves to us after the first few sentences that he can not only think clearly, but can write clearly, that what he

has to say is sound sense, that he has a conception of some very fundamental truths which have been undetected or forgotten or ignored by us and that it would have been better for this country and perhaps some of the other countries if he had written this address years ago and published it so that its teaching was familiar to us all. His audience was surprised and delighted by the lecture and it will be read with pleasure. Lord Leverhulme told us that sixty years ago or thereabouts when he was a grocer's apprentice in Bolton he attended some evening classes in chemistry and he claimed in his modesty that he was therefore almost worthy to be one of us. He did not explain—perhaps he thought we already knew it—perhaps he thought, whether we knew it or not, the information would come better from someone else—that when he began to make money and to buy pictures, it occurred to him that his workers, the captains, the corporals and the privates in his army, would also like some pictures. Acting on this idea he built himself a picture gallery in Hampstead, filled it with choice examples of the art of Lawrence, Linnell, de Laszlo, David Cox and other masters and built another and a larger gallery in Port Sunlight for the gratification of the public there and filled it with pictures as excellent and more numerous than those he has in his own house. He turned a rather dull and swampy tract of inferior country into a beautiful and happy town and then talks to us and jokes with us as if we were a society of very superior people who had paid him a compliment. If you wish to understand the Messel Memorial lecture properly, go to Port Sunlight and look at the pictures—not to the accompaniment of dance music and with the distractions of a bevy of young daughters of the gods, divinely tall and more divinely fair, but simply to see the pictures and the town, then, as you return in the train to London, or Stoke-on-Trent, or Rotherham, or Wigan, or Airdrie or wherever you happen to live, read the lecture. You will miss Lord Leverhulme's twinkling eyes and nimble mind but you will get to the root of the matter:

But Cristes lore, and his apostles twelve,
He taughte, and first he folwed it him-selve.

* * *

The account which Mr. F. H. Carr gave to us of the manufacture and properties of insulin was delightfully simple and modest. All three papers read at Liverpool were good, dealing not with trivialities but with matters of fundamental importance to mankind—health and disease; the use of volcanic heat as a source of power; the composition and origin of coal; but there was a human interest attaching to Mr. Carr's subject which took us some way out of our wonted selves. We gather that insulin is probably an enzyme but we do not quite know, not having any profound knowledge of organic chemistry, what an enzyme is. An alternative name, preferably Greek, is at least better than bare ignorance. It is like a dress suit for a man which is a sign of respectability and puts him on terms of equality with all others similarly blessed. Ten guineas will raise the outcast to the level of a duke or a cabinet minister. A Greek lexicon is an abomination to the Lord, but to the chemist is a very present help in time of trouble. Can no small token of gratitude be arranged for the latest editor of Liddell and Scott? Well, this enzyme can be extracted from many animal tissues and hopes are held out to us that some day a vegetable source may be available. The body is engaged three or four times a day in converting carbohydrates, such as starch, into sugar and converting the sugar into carbon dioxide and other substances. The normal body keeps only a small proportion of sugar dissolved in the blood, the rest being stored up in other organs and in some other form. The insulin acts as a safety valve, a regulator, or a ferment. The process seems to be similar to the making of bread recently described in our columns. In the diabetic subject the amount of sugar dissolved in the blood instead of keeping to its proper low constant level becomes very large and the whole process is thrown out of gear. The insulin somehow gets rid of the extra quantity of sugar in the blood, what the exact process of doing this is, we are not yet told in detail, but the system gets a fresh start and the cures which have been effected are most surprising and impressive. The labours of Mr. Carr and his co-workers have brought down the cost of insulin to one-tenth of what it was, a triumph of patience and skill, of experience in chemistry and engineering. The paper is printed in this week's *Transactions*. The comparison of the human body to a loaf of bread in an oven was forcibly brought to our notice a few days ago when we walked up and down our domestic quarter-deck in an atmosphere with a temperature reported to be 85 in the shade. Concentration of mind and the transference of mind into matter are difficult in these circumstances and abundantly account for any incoherency in the argument we are venturing to submit. If only the heat is as great when any reader peruses this, we shall be forgiven.

* * *

Chemists will experience a sense of regret on hearing of the approaching retirement of Prof. J. B. Cohen, F.R.S., from the chair of organic chemistry in the University of Leeds. After receiving his early education in chemistry at Owens College, Manchester, and after a period in the works of the Clayton Aniline Co., he was appointed demonstrator in chemistry in Manchester in 1884. In 1890 he became lecturer in organic chemistry in the Yorkshire College, Leeds, and when the chair of organic chemistry was established in the University of Leeds in 1904 he became the first professor, a position which he has held ever since. His work on problems of the constitution of organic compounds, his valuable textbooks and his success as a teacher are familiar to all chemists, and the regret on hearing of his retirement will be tempered by the knowledge that he will probably continue his research work in one of the University laboratories. Prof. Cohen, who is an Original Member of the Society of Chemical Industry, has served as a member of Commissions on smoke abatement and chemical warfare and was a vice president of the Chemical Society in 1920-21.

SOCIETY OF CHEMICAL INDUSTRY

THE ANNUAL GENERAL MEETING,

LIVERPOOL, JULY, 1924

MEETING OF COUNCIL

The monthly meeting of Council was held in the Arts Theatre, The University, Liverpool, on July 9, the President (Dr. E. F. Armstrong, F.R.S.) in the chair.

Letters of thanks had been received from Dr. Ernest Fourneau and Dr. Armand Solvay for conferring on them the Honorary Membership of the Society.

The Honorary Treasurer reported that it was a matter of satisfaction to know that the cost of the *Journal* for the first six months of the year is strictly within the estimate laid down six months ago.

Seven new members were elected—Home, 5; Overseas, 2. Attention was drawn to the loss in membership during the year, and certain suggestions were put forward for bringing in new members. It was decided to discuss the whole question at the October meeting.

A very cordial vote of thanks was given to the retiring President for the excellent work he had done during his period of office.

LIST OF MEMBERS ELECTED,

JULY 9, 1924

Beet, Frederick, 30, Northfield Road, Ponders End, Enfield, Middlesex. Metallurgist.

Freeth, Francis Arthur, Heathercroft, Hartford, Cheshire. Chemist.

Harris, Bert A., 19, Russell Square, London, W.C. 1. Engineer.

James, Frederick O., c/o S. A. des Huileries du Congo Belge, Kinshasa, Belgian Congo. Chemist.

Mittberg, Charles H., 10, rue J. J. Rousseau, Asnieres-Seine (France). Chemical Engineer.

Scott, Percy D., Marley Hill Chemical Co., Marley Hill, Co. Durham. Chemist.

Walthew, Reginald C., c/o Miss Ormrod, Kingsway House, Frodsham, Warrington. Fuels Technologist.

ANNUAL MEETING

The Society of Chemical Industry has held more than forty Annual Meetings; that which was held last week in Liverpool was, in the opinion of all competent judges, the best. There was a large attendance of the well-known members of the Society including the President, Dr. E. F. Armstrong and Mrs. Armstrong, the Hon. Treasurer, Mr. E. V. Evans and Mrs. Evans, the Hon. Foreign Secretary, Sir William Pope, K.B.E., the President Elect, Mr. W. J. U. Woolcock, Sir Max Muspratt, Bart., and Lady Muspratt, Mr. and Mrs. Edwin Thompson, Mr. Emile Mond, Mr. and Mrs. C. S. Garland, Prof. G. T. Morgan, Dr. and Mrs. R. T. Colgate, Mr. and Mrs. A. Trobridge, Dr. and Mrs. J. A. Cranston, Mr. S. F. Burford, Dr. and Mrs. E. B. R. Prideaux, Dr. and Mrs. H. Levinstein, Mr. B. A. Burrell, Mr. and Mrs. J. H. Young, Mr. and Mrs. S. J. Pentecost, Mr. and Mrs. L. G. Radcliffe, Mr. and Mrs. F. H. Carr, Prof. P. P. Bedson, Dr. L. L. Lloyd, Mr. E. Gabriel Jones, Dr. A. Holt, Mr. John Allan, Mr. J. A. Reavell, Prince Ginori Conti, the Viscount Leverhulme, the Hon. W. Hulme Lever, Sir Richard Threlfall, K.B.E., Dr. R. S. Morrell, Mr. and Mrs. C. J. Goodwin, Mr. S. J. Tungay, Mr. H. M. Ridge, Mr. and Mrs. R. B. Brown, Mr. E. F. Hooper, Mr. E. Grant Hooper, Mr. T. H. Butler, Dr. W. Cullen and Miss Cullen, Mr. W. H. Coleman, Mr. C. N. Kemp, Mr. W. G. Wagner, Prof. C. O. Bannister, Mr. J. P. Bowley, Mr. J. Bernard, Prof. E. C. C. Baly, Dr. J. T. Conroy, Dr. and Mrs. A. C. Cumming, Mr. and Mrs. W. A. Davis, Dr. P. Dvorkowitz and Miss Dvorkowitz, Dr. J. V. Eyre, Prof. F. Francis, Prof. and Mrs. I. M. Heilbron, Mr. F. E. Hamer, Dr. R. Lessing, Mr. R. Muspratt, Mr. G. W. Marlow, Mr. W. Macnab, Mr. and Mrs. T. H. Pope, Prof. W. H. and Mrs. Roberts, Mr. H. Wigglesworth and Dr. and Mrs. J. P. Longstaff.

Professor C. J. van Nieuwenburg represented the Dutch Chemical Society, of which he is President. Dr. A. C. Fieldner represented the American Chemical Society. Dr. and Mrs. Adan represented the chemical industry of Belgium.

It is becoming customary for members to bring their wives and daughters and so soon as this is more widely known the practice will spread. Chemists are more frivolous than formerly, they are more human, less learned, better dressed, have prettier wives and sit up later. Possibly this is true of other classes of mankind, but this tendency towards light-heartedness and away from solemnity is a sign of the times. The editorial department of the *Journal* cannot escape the infection or fashion try as it will. The editorial columns of *The Times* and *Morning Post*, of the *Railway Gazette* and the *Investors Chronicle* are not so serious as they were before the War. Confident in their Socialist Governments, Kings attend race-meetings and Princes enjoy Scenic Railways. As we travel through life let us laugh by the way: what is all the world to a man when his wife is a widow? It is true one old, perhaps an original, member, Mr. Grant Hooper, sighed for the earlier, worthier days obviously disliking the originality of some of the Society's journalistic features. But even he was not angry about it: he protested but in so good-natured a fashion that it could almost be supposed that saying he would ne'er consent, he consented. So long as the *Journal*

never delays or refuses a serious piece of real work, and this is a cardinal feature of the Society's practice even now, let the chemists have their badinage. But if badinage be accompanied by spending money faster than it comes in, the jest has a hollow sound. When the columns of this *Journal* become really serious, Mr. Cullen and Mr. Grant Hooper should be very suspicious that financial anxiety worries the Council and black care sits behind the editorial horsemen.

On Tuesday evening the members assembled at the Midland Adelphi Hotel and were received by the President and the Local Committee. No one can say of the President, facetious as he can be, that mere prattle, without practice, is all his chemistry; that may be true of some who masquerade as chemists; but when the President chooses he can be in deadly earnest. Has he not provided a monumental address on the "Chemistry of Fats," and also organised a book "Chemistry in the XXth Century," which might be described as Coke described Littleton's "Tenures"? "the most perfect and absolute work that ever was written in any humane science . . . a work of as absolute perfection in its kind and as free from error as any book that I have known to be written of any humane learning."

The Formal General Meeting was held on Wednesday morning in the Arts Theatre of the University of Liverpool. The proceedings are fully reported in the Society's Transactions and require but little comment. The Honorary Treasurer very kindly complimented the editorial staff on their alacrity in effecting economies when called upon to do so and shown how. Cutting down printing and paper expenses is the sort of economy which delights an editor; enough of it would enable some editors to have a fairly restful time, practise billiards and read Horace. Does not this favourite author say in the "Ars Poetica" that even a very mediocre lawyer, not so eloquent as the President and not so erudite as the previous President, may be nevertheless of some use, *nec tamen in pretio est?* Some of these old classical authors are full of most up-to-date matter.

The visit to the White Star Liner the "Celtic" was very pleasant. How often have chemists in the Atlantic or the Indian Oceans longed for so placid a water as the Mersey! Oh sweet as to the toil-worn man, the far-off sound of rippling river, as to cadets in Hindustan the fleeting remnant of their liver—and so on. Here were all the comforts and the luxuries of a floating palace with none of the disadvantages: the Mersey is a good place in which to practise ocean voyages and a few trial trips in the "Celtic" on its waters would be a good training for many amateur sailors.

In the evening the Lord Mayor received the Society in the Town Hall: dancing and dancers were pursued until midnight; the reflections which such a spectacle induces in a philosophic mind have been already set forth.

The visit to the works of Messrs. Joseph Crosfield and Sons, Ltd., on July 10, was exceptionally well organised. During the lunch the Brass Band of the works played good music and played it well; it is much more agreeable to have good music as an accompaniment to a good lunch than the singular substitute in which the saxophone plays so strident a part. The works itself is an interesting one, well planned and with a variety of processes carried on; the majority of the visitors preferred the perfumery department, the printing, the box-making and the packing departments to the actual soap-boiling. Great pains had been taken to arrange the visitors in small parties, to keep these distinct from each other, to explain to each what was of special interest, and to ensure a steady flow of these parties along the ordained route. A fire-drill display was equally well arranged, the girl guides, boy scouts and firemen carrying out their duties in a manner which denoted frequent practice. Many of the visitors considered this visit the most interesting item in the whole programme but they were hardly in a critical mood, having been allowed a cool room in which to take tea and to rest, and being presented on leaving with soaps, perfumes and brilliantine. A suitable frame of mind is essential to a sound judgment. Did not someone comment on a well-known passage?: "Swap his whole kingdom for a hoss, a hoss, mind you, he hadn't seen, let alone not being in a condition to be a judge of hoss flesh!"

THE ANNUAL BANQUET

The Annual Banquet was held in the Midland Adelphi Hotel, and was quite a brilliant gathering. About three hundred guests were present and were seated at small tables, so that there were good opportunities for conversation. The President announced that in reply to the Society's telegram to the King, His Majesty had been pleased to send the following message

TELEGRAM

From
BUCKINGHAM PALACE
To
THE PRESIDENT, SOCIETY OF CHEMICAL INDUSTRY, UNIVERSITY, LIVERPOOL.

THE KING SINCERELY THANKS THE MEMBERS OF THE SOCIETY OF CHEMICAL INDUSTRY ASSEMBLED AT THEIR ANNUAL MEETING FOR THE LOYAL ASSURANCES CONTAINED IN THEIR MESSAGE WHICH HIS MAJESTY AS PATRON MUCH APPRECIATES.

PRIVATE SECRETARY.

The speeches were facetious rather than of the formal variety. The President proposed "The City of Liverpool and the Liverpool Section of the Society of Chemical Industry." He dealt with the means of getting on in the world, and gave as an instance Lord Leverhulme who was sitting close by. Lord Leverhulme, he said, had kept his mind open for humanity as well as for business and science. He pleaded for a broad outlook on the part of chemists, that they should not be merely chemists with a belief that it was improper for them to have any understanding of anything else. Liverpool was the natural home of the heavy chemical industry. Its facilities for export, its proximity to the brine and salt of Cheshire and to the coal-fields of Lan-

cashire and Yorkshire, together with the exceptional brains of those who had founded or were now carrying on the industry, had combined to place it in a secure position, from which with smiling face they could withstand the competition of the world.

The Lord Mayor of Liverpool, Mr. Arnold Rushton, in reply said they were proud of their city, and when they spoke of it everything was spoken in the superlative; they were proud of their industries, even one industry which they preferred to keep at a safe distance, such as Widnes.

Mr. Edwin Thompson, the chairman of the Liverpool Section and a prominent member of the City Council, also replied to this toast, and paid a pleasant tribute to Mr. Gabriel Jones, the Honorary Secretary, and to others who had helped to make the meeting the success it was.

Mr. W. J. U. Woolcock, the president-elect of the Society, proposed the health of "The President" and briefly dealt with the important services to industrial chemistry rendered by Dr. E F Armstrong during the two years of his presidency.

Dr. Armstrong briefly replied.

After the conclusion of the banquet dancing was begun and continued until midnight. In Liverpool, Presidents, Lord Mayors, Viscounts, and other holders of dignified office appear to enjoy dancing as much as ordinary mortals; their proficiency is strong presumptive evidence of many mis-spent hours.

THE LARDERELLO NATURAL STEAM POWER PLANT

By PRINCE GINORI CONTI

The natural steam springs of Tuscany, containing boric acid, which are more generally known under the name of "soffioni boraciferi," have been often described in geological and chemical treatises.

They are to be found in several spots in the neighbourhood of a large village called Castelnuovo Val di Cecina, which is situated near the southern border of the Province of Pisa, not far from the ancient town of Volterra.

These springs are evidently the remnants of the very remote volcanic activity which contributed to the formation of the hilly range running roughly parallel to the Tuscan coast and which is named "Catena Metallifera" from the presence of metallic ores (copper, iron, zinc, lead and antimony). The mountainous system of the island of Elba is probably connected with it, and traces of thermal activity can also be found at some distance from the actual region of the "soffioni," such as hot springs in the neighbourhood of Massa Marittima and sulphurous vents called locally "Putizze."

The territory of the soffioni covers roughly an extension of about 225 square kilometres, and the groups of soffioni, which are situated within it, are those of Larderello, Castelnuovo, Sasso, Monterotondo, Lago, Lustignano and Serrazzano; another group, Travale (of minor importance) lies several kilometres to the east, towards Siena.

Larderello, the better known of these groups of soffioni, was so called after the founder of the Tuscan boracic industry, Francesco De Larderel, who, in 1818, started manufacturing boric acid (the presence of which had been ascertained since 1790 in the waters issuing from the soil together with the natural steam, and subsequently in waters resulting from the condensation of the same steam) by concentrating these boric solutions by means of natural heat, thus genially utilising the steam of the soffioni.

For this purpose, it was necessary to provide sufficient quantities of steam and since the initial

Prince Ginori Conti

period of the works, special wells were bored in the volcanic soil.

It is needless here to mention the various stages of development of the chemical industry of the Larderello Works; details can be found in various publications, pamphlets and scientific journals, from the pen of distinguished scientists of all countries who visited and described this singular phenomenon. Suffice it to say, that, whereas the purely geological and chemical side of the question was amply studied, the other and equally interesting question, viz., the feasibility of utilising natural steam as a means of generating mechanical and electrical power, was ignored till the beginning of 1904, when as general manager of the Larderello Works I first attempted the use of natural steam with a small engine of a few h.p. The problem was a fascinating one and contained several incognita.

The presence, in the soffioni steam, of considerable volumes of gases (carbon dioxide, sulphuretted hydrogen and others, amongst which helium) was evidently the first of these incognitæ, especially with regard to action on metals.

The results, however, were quite satisfactory, and a further experiment was carried out in 1905 with a larger engine of about 20 h.p., driving a dynamo for the illumination of the works. This engine has worked, practically without interruptions, for over ten years without the slightest inconvenience.

New wells were drilled and systematic studies were carried out regarding the measures of output in steam, constancy of temperature and pressure, etc.

In 1912 I was elected chairman of the Società Boracifera di Larderello, a limited company resulting from the incorporation of two other minor concerns with the Larderel Company, and decided to attempt a larger experiment with a 250 k.w. steam turbo-alternator, and finally, in 1914, the erection of the Larderello Power Station was begun. This plant is actually composed of three turbo-alternators of 2500 k.w. net power each, two of which are running, the third being held in reserve.

The direct use of natural steam with turbines was not then feasible, because the available pressure from the wells was very low and therefore the efficiency of the turbines depended entirely on the vacuum in the condenser, and an enormous dissipation of energy would have been inevitable in order to remove the gas contained in the steam.

It was therefore necessary to use natural steam as a means of producing pure steam for feeding the turbines. Special evaporators were consequently installed, similar in principle to water tube boilers. This evidently stood for complication of plant and loss of efficiency, and experiments were immediately pursued with the object of eliminating gas from natural steam. Signor Bringhenti, one of the company's engineers, very genially solved the problem by means of an extremely simple apparatus which, better than a boiler or an evaporator, can be styled as a deparator. The steam issuing from this apparatus contains only a very slight portion of the original quantity of gas, and can therefore be used for feeding the turbines. The advantages of this apparatus are numerous and the principal one is the total abolition of tubes, which were a source of disturbance and of considerable expense. These tubes could not be made of iron or steel, because the H_2S contained in the steam by which they were externally heated, soon formed a coating of sulphide of iron which greatly diminished the coefficient of conductivity. It was imperative to use a suitable metal, and aluminium was tried with tolerably good results, but it will be readily understood that corrosion could not be entirely avoided, while the mechanical properties of aluminium did not prove to be entirely satisfactory. Leakages consequently occurred, allowing natural steam with gas to enter the tubes, thus altering substantially the working conditions of the turbines.

As noted above, up to a short time ago, practically all the wells drilled at Larderello gave steam at very low pressure. In fact the available pressure corresponding to maximum output was barely 2 atm. abs. The pure, or "secondary" steam generated by the evaporators has a pressure of 1·5 atm. abs. and the working pressure of the turbines is only 1·25 atm. abs. The turbines are therefore low-pressure types, similar to exhaust turbines, and depend mainly on condenser vacuum. This explains the importance of having to deal with limited and constant quantities of gas in the condenser itself, the air pumps being proportioned to certain percentages of gas, the varying of which alters very materially the output of the turbines.

The condensers were originally of the surface type, but they have been since modified as jet condensers in order to obviate the necessity of tubes. Cooling water is provided by means of 3 large refrigerating towers.

No distinctive features are to be noted in the turbines, which are of the reaction double flow type, and are running at 3000 r.p.m. They are coupled to 3-phase alternators, generating current at 50 periods and 4000 volts. The electrical plant is entirely normal, and the only noticeable item is the extensive use of aluminium for bus bars, etc., in order to avoid, as much as possible, trouble with sulphuretted hydrogen in presence of copper.

The weak boric solutions which are the result of the condensation of the natural steam in the evaporators, are subsequently used for making boric acid. Thus, about 500 kilos of boric acid are obtained daily from the Larderello power plant.

The current generated by the turbo-alternators is elevated to the different voltages required. These are: 16,000 volts for lines conveying power to the neighbouring villages, to the town of Volterra, and to the different works of the company (which are 8 in number, including Larderello, and have all electric power, excepting the small and distant works of Travale), and 33,000 to 39,000 volts for main lines joining Larderello to the large systems of the power companies for Central Italy. Larderello is generally working in parallel with the hydraulic power stations near Terni (in Umbria, not far from Rome), and they are all occasionally in parallel with the Northern Italian lines belonging to the Adamello plant (on the Alps above Brescia).

At the Lago works, another small power station has been erected. It contains the first 250 k.w. unit formerly at Larderello, and has been extensively used for experimental purposes.

* * * * *

Since the erection of the plant which has been summarily described in the preceding paragraphs, several new wells have been drilled by the Società Boracifera, using more powerful machinery which has allowed greater diameters and greater depths to be reached. The results have surpassed all expectations. At Castelnuovo and at Serrazzano (two of the works where it was not considered that very high outputs in steam would be obtained) two very remarkable wells have been drilled. The Serrazzano well gives about 24,000 kilos of steam per hour at maximum output and fully open, at a pressure of 2 atm. abs., but the output does not

fall so rapidly as in the generality of the former wells when the valve is partially closed and the pressure rises, so that about 13,000 kilos per hour have been measured at a pressure of 5 atm. eff. At Castelnuovo an extremely powerful well gives 60,000 kilos of steam per hour at 2 atm. abs., but again the output does not fall rapidly when higher pressures are obtained. At Larderello a new well gives 35,000 kilos per hour: the mean output of the former largest wells being about 25,000 kilos.

A more complete idea of the importance of the phenomenon will be obtained by considering that in Larderello alone actually over 150,000 kilos of steam are emitted per hour.

It is hardly necessary to emphasise the importance of these results. The possibility of having very considerable quantities of steam at higher pressures than those available with the actual plant opens quite a new outlook on the problem, and the necessary studies and experiments are being carried out to determine the most efficient manner of utilising these very considerable sources of power.

Another experimental turbine has been installed at Serrazzano. It exhausts direct into the atmosphere and is fed with natural steam. The exhaust steam is utilised for heating concentrating apparatus for boric solutions. Thus all complications arising from evaporators and condensers are abolished and the ideal simplicity of this plant amply compensates for higher steam consumption.

It is proposed to follow up the very satisfactory results obtained by this little plant by installing units of appropriate power fed with natural steam at about 2 atm. eff. with exhaust into atmosphere.

* * * * *

Several conjectures have been made as to the origin of the "soffioni" and also as to the presence of boric acid in the steam, but the various theories proposed have only, as yet, the value of hypothesis.

The phenomenon is obviously due to latent, or better, to nearly extinct volcanic activity and it is quite reasonable to suppose that the various spots of the soffioni region are linked to a main centre of activity.

Geological differences between the soil of these various spots can account for slight variations in the composition of the steam, such as greater or smaller percentage in gas, but the data are as yet incomplete and it can only be hoped that the systematic studies which are being pursued will enable us to obtain more complete knowledge of this fascinating problem.

It is hardly necessary to explain the importance of the Larderello plant as an entirely novel method of obtaining power which has been very appropriately called "Geothermal."

Sources of natural steam are quite abundant in various parts of the world where volcanic activity has been at work.

In the Italian Peninsula itself, the "Solfatara" of Pozzuoli, near Naples and the regions round Etna, as well as the islands of Stromboli and Vulcano, are being studied from this point of view.

A very wide field of research is America. In Alaska, the "Valley of Ten Thousand Smokes" has been very completely explored by the geologists of the U.S. Government. The phenomena are not very different from those of Tuscany, but the volcanic region is far greater in size. In California experiments are being made, and very fair amounts of steam have been obtained.

In South America (Chile and Bolivia), near the now extinct volcano "Tatio," steam springs of remarkable importance have been found. The ones on the Chilean side have been studied, with a view to erecting a power plant, by one of the engineers of the Larderello Company.

Japan is another land where natural steam springs abound. Several enquiries have been made by Japanese engineers and scientists as to the methods followed at Larderello and considerable interest has been shown regarding my work.

Finally, New Zealand can be quoted. The Rotorua region is certainly very rich in natural steam and very interesting results could be obtained from the study of that neighbourhood.

PLEA FOR CHEMICAL GRADUATES

Professor G. T. Morgan, F.R.S., head of the Chemical Department of the University of Birmingham, in a letter to the Birmingham newspapers (in which he refers to the degree lists recently published), makes an appeal to manufacturers on behalf of chemical graduates. He observes: "Apart from recommendations to many teaching appointments, I have, during the last four years, assisted in placing some seventy chemical graduates in industrial posts. The geographical distribution of these positions is, however, curious and intriguing. In the majority of cases these appointments are outside the Birmingham area. A chemical graduate, like the prophet of old, is not without honour save in his own country. Yet it seems to me that many local industries, being largely based on chemical principles, would profit from the co-operation of fresh young minds chemically trained, and many of them sharpened by research experience. My experience gained in other districts is that a well trained young chemist will earn his salary (which is usually not princely at the outset) plus a reasonable profit for his employer.

"From time to time I am requested to give expert advice to local manufacturers wishing to make a new chemical product or to improve an existing process, but owing to the pressure of multifarious duties I have but little time and energy left to devote to such problems. To these enquirers I would suggest a better and more efficacious way—namely, to enlist the whole-time services of a chemical graduate, to give him reasonable facilities for working out the problem, and not to be too disappointed at the slow rate of progress during the first year. The astute directors of one London firm of world-wide reputation have found that a chemical research laboratory staffed almost exclusively with Birmingham graduates saves them annually many thousands of pounds in their contracts for raw materials. Obviously a similar plea could be made out in regard to the utilisation of students trained in other branches of learning."

THE WORLD POWER CONFERENCE AT WEMBLEY

The Second Week's Papers

(From our Special Correspondent)

The second week's papers comprise the sections devoted to power transmission and distribution, including power-station transmission lines, cables, and high voltage D.C. transmission; gas and fuel sections; internal-combustion engines; power in industry; power for road and air transport; research; the domestic uses of power, and also agricultural applications, electro-chemistry; industrial welfare; power for rail transport; electro-metallurgy; publicity, power for water transport; technical and commercial education; standardisation, and various general meetings from the point of view of the future possibilities of making the World Power Conference a permanent institution.

As before, it is impossible to attempt to give any summary of these multitudinous papers, and still more so of the discussion, so one can only pick out a few subjects which are of more particular interest to the technical chemist and chemical engineer.

Lately, we have heard much of super-power station schemes, and apparently we are now going to hear much more with the publication of two "Government" Reports, one of which, "Coal and Power," has appeared. The world seems fated to erect larger and larger electricity stations, and we are well within sight in America of the 500,000 k.w. installation, of which it is difficult to give any idea of the magnitude. Thus, to supply the cooling water would require a river about twice as big as any in the United Kingdom, so that the trend of super-power station sites would seem to be necessarily towards the sea. In the super-power station, about which opinions greatly differ, one of the chief problems is the transmission of the power, since the tendency is to concentrate production in a few areas. Mr. C. H. Mertz's paper, "Transmission and Distribution of Electrical Energy," is thus very interesting to power users. He states that, roughly, the capital cost of the transmission and distribution of electricity over a considerable area is about the same as the capital cost of the station itself, and apart from fuel, the working costs of the two are also about equal. Mr. Mertz is of the opinion that in the future it may be possible to use single core underground cables at no less than 132,000 volts, although this is not feasible at present. Further, he thinks that various distributing net-works should be inter-connected, in spite of the increased complexity and risks of faults. It is interesting to note, also, that switchgear to-day bears too high a proportion of the capital cost of the station, and that considerable economy in this direction remains to be effected. Altogether this section on the transmission of electrical energy seems to be one of the main items at the Conference.

From the point of view of the technical chemist, certainly the most important section in the second week was that relating to gas and fuel, together with the allied subject of low-temperature carbonisation, which seems to have strayed over from last week, along with pulverised fuel and various other subjects, at any rate as far as the discussion was concerned. Low-temperature carbonisation has received extremely scant attention at the Conference, there being only one paper, by Dr. C. H. Lander, of the Fuel Research Board, although it is also referred to in another paper by Sir George Beilby. It is unfortunate that papers have not been read by some of the many people who have had almost lifelong experience of large scale low-temperature carbonisation. In the discussion considerable attention was given to one of the most interesting of all processes, that is the "Caracristi," which is now about to be operated by the Ford Motor Co. It is well-known that at Detroit the Ford Company has probably one of the most remarkable boiler plants in the world, burning pulverised raw coal and blast furnace gas on enormous boilers, a second section of which – at a cost of about 6 million dollars—is just to be started up. It is the intention of this company to adopt the scientific method of burning in a pulverised condition low-temperature fuel after the more valuable paraffinoid liquid products have been separated, thus at the same time obtaining a large supply of motor fuel. Whether a practical success will be achieved remains to be seen, but certainly the Ford Company has an uncanny knack of carrying through what it sets out to accomplish.

It is interesting to note, with regard to Sir George Beilby's paper, in which he describes some work that has been undertaken by the Fuel Research Board on carbonising roughly-crushed coal in shallow trays, that this principle seems to have been first used about the year 1860. The real pioneer of this method of carbonisation is R. S. Richards of the "Richards-Pringle" process, who realised that in order to carbonise coal in this way it is necessary to divide it up into narrow segments by means of metal divisions, so as to increase the heat transmission to the heart of the layer.

Incidentally it is much to be regretted that one of the scientific pioneers of low-temperature carbonisation, Prof. S. W. Parr, of Pittsburg, who originated many of the modern principles, such as for example coal-blending, the preparation of briquettes direct from a semi-viscous charge of heated coal, and the carbonisation of briquettes in general, could not have been present or contributed a paper.

The whole question of the science of coal carbonisation, whether by high or low temperature methods, seems to be in a state of flux, and not the least interesting feature is the fact that metallurgical coke itself is now being threatened, as was pointed out in the discussion, from two sources. The first is the low-temperature reduction of iron ores by means of pulverised raw coal, which would eliminate blast-furnace metallurgical coke altogether, and, secondly, there is the preparation of fuel by the carbonisation of briquettes, resulting not only in paraffinoid liquid products, but at the same time a material which is harder than metallurgical coke and is also much more chemically re-active.

With regard to the gas industry, Dr. J. S. G. Thomas and D. Chandler read a paper on the advan-

tages of illumination by gas, which seems to go over very well-covered ground in most respects. It seems, however, to be quite a new idea that the blackening of ceilings is not due to defects in gas lighting, but is really now one of its greatest advantages, since, to use Dr. Thomas' own words: "The flame of gas lighting burners effectively destroys the myriads of potentially harmful micro-organisms present in the air of living rooms . . . The flame is their crematorium, and their charred remains are found on the ceiling above the flames." One looks forward with considerable interest as to what our friends, the electrical people, will have to say on the matter.

The general impression gathered from reading somewhat hastily the various papers under these sections, and listening to the discussions, is that the gas industry is, very wisely, strongly opposed to any further Government control, and that the question of some proper scientific system of co-ordination in dealing with coal supplies is obviously required. Dr. E. W. Smith had a paper on this question, and the subject was also dealt with in varying degree by several other speakers. Dr. Lessing and Mr. Sinnatt, for example, discussed the question of conveying about the country millions of tons of ash, which ought to be washed out of the coal, whilst the importance of moisture is also not generally realised. It is certainly a curious, not to say uncomfortable, fact that very nearly 200,000,000 tons of coal is purchased every year in Great Britain without the slightest guarantee as to its quality, especially as regards the heating value and the percentage of ash and water. There is no real reason why coal should not be sold in most cases, especially to large consumers, on a sliding-scale basis depending on the heating value, and whilst naturally there are many complications in this connexion the general principle would be infinitely more satisfactory than at present. It is common knowledge, as compared with pre-war days, that coal has deteriorated in quality, so that gas works and electricity stations, for example, are particularly badly hit, since coal is by far their largest item of expenditure.

In general, the World Power Conference can certainly be written down as a success, although there are many points that afford material for criticisms. It is unfortunate that the discussions have played such an extremely small part in the proceedings, and many of the most famous engineers in the world, who have congregated together practically for the first time, have been limited to a scanty five minutes, which seems hardly adequate. Also, serious confusion appears to have arisen with regard to the length of the papers.

We can only recommend, as previously stated, that everyone interested should send to the World Power Conference, 36-8 Kingsway, W.C. 2, for a complete schedule of the 417 papers, the price of each reprint being clearly marked.

Prof. H. Precht, who was closely connected with the development of the German potash industry, has died, aged 72 years.

FORTHCOMING EVENTS

Sept. 4 and 5. IRON AND STEEL INSTITUTE, Autumn Meeting at British Empire Exhibition, at 10.30 a.m. each day. (1) "Changes of Volume of Steels During Heat Treatment," by L. Aitchison and G. R. Woodvine. (2) "Investigations on the Herbert Pendulum Hardness Tester," by C. Benedicks and V. Christiansen. (3) "Effect of Changes in Total Carbon and in the Condition of Carbides on the Specific Resistance and on some Magnetic Properties of Steel," by E. D. Campbell and G. W. Whitney. (4) "Pickling: The Action of Acid on Iron and Steel, and the Diffusion of Hydrogen Through the Metal," by C. A. Edwards. (5) "Examination of Iron from Konarak," by J. N. Friend and W. E. Thorneycroft. (6) "On the Nature of High-Speed Steel," by M. A. Grossman and E. C. Bain. (7) "Improvements in the Brinell Test on Hardened Steel, including a New Method for Producing Hard Steel Balls," by A. Hultgren. (8) "Present Position of the Theories of the Hardening of Steel," by W. Rosenhain. (9) "Effect of Free Surfaces on the Plastic Deformation of Certain Metals," by F. C. Thompson and W. E. W. Millington.

Sept. 8 to 11. INSTITUTE OF METALS. Annual Autumn Meeting, to be opened at the Institution of Mechanical Engineers, when W. M. Corse, S.B., will deliver the third annual Autumn Lecture. On September 9 the morning will be devoted to reading and discussion of papers, followed by luncheon at the Connaught Rooms, Kingsway, the afternoon to be spent at the British Empire Exhibition. On September 10 further papers will be presented for discussion, the afternoon being devoted to visits to works. A reception will be held in the evening at the National Physical Laboratory, Teddington. A detailed programme will be issued in August.

Sept. 15. BRITISH EMPIRE EXHIBITION. Conferences of Engineering Societies, to be held in Conference Hall No. 1, at 10.30 a.m. Short papers on various Engineering Subjects will be read and discussed. Further information and tickets may be obtained from the Secretary, Society of Engineers, 17, Victoria Street, Westminster, S.W. 1.

BRITISH RESEARCH ASSOCIATION FOR THE WOOLLEN AND WORSTED INDUSTRIES

Particulars have been issued of research fellowships and advanced scholarships awarded by the above Association. The Fellowships are of the annual value of £200, and are granted for one year, but may be renewed for a second year. The advanced scholarships will cover fees and adequate maintenance and are intended to enable students to specialise. No limitation is placed on the kind of work to be undertaken, and the scholarships are open to all suitable persons. Applications must be sent to the Secretary of the Association, Torridon, Headingley, Leeds, before July 31. Applicants for fellowships should give particulars of training, qualification; the suggested investigation and the place where it is proposed to carry it out.

THE KELVIN CENTENARY

The centenary of the birth of Lord Kelvin was celebrated on July 10 at the Institution of Civil Engineers in presence of a distinguished audience. In presenting the Kelvin Medal to Prof. Elihu Thomson, Sir Charles Morgan said the medal was founded in 1914 to be awarded triennially as a mark of distinction for work of the kinds with which Lord Kelvin was particularly identified. In reply, Prof. Thomson said it was very gratifying that the medal testified to a broad appreciation of scientific effort and of engineering efforts of which his own career was accepted merely as an example, but he regarded it as a tribute to the labours of his fellows in America and elsewhere. Lord Kelvin was an example of what a man great in science and engineering should be: thought and work unceasing. He was lovable as a man, unequalled as a scientific exponent; and our earliest and greatest electrical engineer. Sir J. J. Thomson, F.R.S., then delivered the Kelvin Oration, in which he pointed out how much British science owed to Lord Kelvin, who had made vast additions to our knowledge and left an example of unremitting devotion to a great ideal.

The Kelvin Centenary Dinner was held on July 11, in the Connaught Rooms. Lord Balfour (who presided), in giving the toast "in memoriam Kelvin, 1824-1924," said that Kelvin instinctively applied knowledge derived from the pure study of natural law to the needs of mankind. He was not merely a man of science, but also a great inventor. The future would look back to him as the founder of that sure knowledge of the fabric of the world on which must be based most of our hopes for the material advance of humanity.

ACADÉMIE DES SCIENCES

On July 7 Prof. Le Chatelier communicated several papers. In one, Monsieur Lebeau described his investigations on the gas produced on heating graphite. The second, by M. Lemarchand, dealt with equilibria in saline solutions; in the third, M. Jolibois discussed the action of tetra-ethyl lead in internal-combustion engines; and in the last paper M. Chassevent examined the question of the heat of solution in setting plaster. Prof. Perrin communicated a paper by M. Job on the decomposition of ethyl iodide by light. Prof. Lindet discussed a paper by M. Brioux on the influence of spraying dilute sulphuric acid on weeds and on the soil. M. Guignard stated that according to some work by M. Goris, three glucosides existed in fermenting green vanilla, and that one of these glucosides was the cause of the aroma of vanilla, an aroma not possessed by synthetic vanillin. Describing work by MM. V. and R. Sartory, M. Guignard stated that bichromate of copper was twice as strong an antiseptic as potassium bichromate in treating the potato disease due to *Phytophthora infestans*. M. Delandre stated that M. Végard at the Cryogenic laboratory at Leyden had shown that the aurora borealis was due to cathode rays acting on liquid nitrogen.

CORRESPONDENCE

THE ACTION OF LIGHT ON CONDENSED MILK

Sir,—In the examination of sweetened condensed milk I have recently noted that light has a very pronounced effect upon the colour of the material. Condensed milk left exposed to ordinary daylight in transparent glass vessels for two hours only, showed a darkening on the surface towards the light, whilst the portion lying away from the light remained practically unchanged. Similar samples kept in the dark remained unchanged.

In my opinion this phenomenon explains to some extent the "dead" or brownish appearance noted in many samples of freshly manufactured sweetened condensed milk which are otherwise quite satisfactory; the light probably causes the change while the product is undergoing cooling in open mixer-cylinders. This suggestion is borne out by the observation that the material, when cooled in the dark (as it is in some cases) is superior in appearance.—Yours faithfully, STEPHEN B. BOWYER

Edward Sharp & Sons, Ltd.,
Maidstone.

THE ENGLISH LANGUAGE

Sir,—I have read with interest the communication from Mr. A. W. Allen in the issue of May 23, also the editorial remarks thereon, and I should like to reply to the important points raised.

In like manner to Mr. Allen I hold no brief for any particular British book, as I consider that every book, British or American, has to stand or fall on its own merits. There are two reasons why I thought it desirable to draw attention to Dr. Abbott's "How to Write Clearly." The first is that it is a book of only seventy-eight pages, giving valuable information in the form of rules, each followed by examples showing both their use and the effect of their neglect. Numerous exercises follow, each with reference numbers to the rules that should be applied. Bearing in mind that many chemists and engineers are extremely busy men, it seems to me that a concise book such as this is the very thing for them. Secondly, being an old pupil of Dr. Abbott, it is a pleasure to draw the attention of readers of this *Journal* to one of the smaller works of an eminent scholar who was Senior Classic of his year at Cambridge and the winner of many University prizes.

Next, I must entirely dissociate myself from any "peevish antagonism" to transatlantic writers on any subject. The Americans are well-known, for example, as Dictionary makers. Up to a point I swore by Ogilvie's "Imperial Dictionary," but when I saw Funk and Wagnalls' "Standard Dictionary" I bought it at once, and when their "New Standard Dictionary" was announced I sent an order to their London office for a copy as soon as ready. The up-to-date information that this work contains is simply surprising, and scarcely a week passes without my consulting it. In addition to this chemical works by Wiley, Leach, Sadtler, Prescott, Leffmann and many others are on my

book shelves and in frequent use. According to my experience American chemists are held in high esteem on this side.

To return to Mr. Allen's criticisms, " some dozen " means about a dozen, say eleven or fourteen, the word " some " not being here used in the colloquial sense of big in number or size (*e g*, Wembley is *some* Exhibition). Mr. Allen's statement that, " we are realising the economic value of condensation and the beauty of simplicity to an extent that was not recognised when Dr Abbott's book was first published," is entirely wide of the mark, as rules aiming at conciseness, clearness and force in expression form the very foundation of Dr. Abbott's book In proof of this let me quote the author's third rule: " Avoid useless circumlocution and ' fine writing.' "

I used the abbreviation " etc " simply to save space in our *Journal* by avoiding repetition of an extract previously given in full. I was merely having a sly dig at present-day Members of Parliament and others.

In conclusion, let me express the hope that the discussion that originated in an editorial paragraph in our *Journal* for last December may bear fruit in a more clear, concise and effective use of our English language by chemists and engineers, both American and English. - I am, Sir, etc ,

A. E JOHNSON

24, Parkdale Wolverhampton
July 12, 1924

Sir,— In your May 30 issue appear two letters that invite comment. One is from Pedant, whose method of signature suggests the nobility, but whose appellation is not in Whitaker. The writer infers and modestly attempts to prove that he is a purist ; and one would therefore expect to find that a pseudonym, if used, would be placed between what he terms inverted commas- a designation that a real purist would avoid, by the way, because of obvious inapplicability and inaccuracy. Pedant, therefore, as a " splitter of hairs," is as inconsistent as the majority. To reply to his criticisms, however Etc. is an abbreviation to be found in standard English Dictionaries. In spite of correction, I still believe that its use is common and accepted as " good English " , the quotation marks were added purposely to prevent a literal interpretation of the last two words in the sentence. Moreover, I see no inaccuracy in the direct statement as to " The use of etc . . . ' Pedant suggests that the sentence in which these words were used was meaningless to him, to which I would reply that my letter was not written as evidence of an ability to satisfy self-styled purists and local interpreters of the niceties of composition in all the English-speaking countries. My mistake was one of omission : I should have mentioned that the abbreviation is sometimes permissible, to prevent needless repetition. Thus, in a recent discussion, the title of a paper on electrochemical work in Chile was referred to as " the Electrolytic Tank House, etc ," to emphasize the words to which attention needed to be drawn, without repeating what was well known to every reader. Its use at the end of letters to your *Journal* may be justified on similar grounds.

Mr. Hugh F. K. Picard's letter is of the red-herring order. He has discovered and wishes it to be known that the author of " Technical Writing," published in the United States, was born of English parents, and that he received a technical education in London. He might have added that Mr Rickard first saw the light in Italy, and acquired his earliest literary impressions from a German nurse and a Russian tutor, speaking the language of both before he spoke English. But what has this to do with Mr Johnson's original inference that any effort originating in the United States to help writers and to simplify technical composition should be considered presumptuous and a work of supererogation ?

I repeat, I hold no brief for any particular publication on technical or scientific composition. I differ from Mr. Rickard in regard to several of his contentions, and I am not in entire agreement with Sir Clifford Allbutt ; but I believe that the good resulting from the study of any book of the character under discussion, whether written in England or in the United States, greatly outweighs the harm that might possibly be done by an occasional overstressing of the personal viewpoint, inevitable in so controversial a subject, and by a commission of minor errors that indicates the fallibility of humans, including the best writers and the most experienced literary critics Mistakes must be admitted by all except the dead, those " out of the running " and the few who evade personal responsibility by the adoption of a pseudonym.

Professors are not all-wise ; parents are not perfect ; preachers are not invariably free from frailty in moral matters ; nevertheless, the consequences of fallibility among the members of each group are considered insufficient to justify a suspension of all educational or corrective action. But when an effort is made to help the scientist to become articulate and intelligible to ordinary mortals, to lead the technician to appreciate the economy and force of brevity and clarity in the use of the English language, a scramble occurs among purists and " hair splitters " as to who can be the first to demonstrate once again what editors and experienced writers are fully aware the imperfections of missionary effort and the vulnerableness of critics. The pity is that such action discourages initiative and fosters self-satisfaction among slovenly writers. I am, Sir, &c

A. W. ALLEN

Berkeley, California

THE WASTE OF COAL

Sir,- With regard to the statement made in a recent issue (July 11 1924) of *The Times* by Mr Evan Williams, of the Mining Association of Great Britain, extracts from which have been reproduced broadcast in the press, will you allow me to correct one extremely misleading impression given by this statement. We are informed that the colliery proprietor is not responsible for waste of coal after it has been brought to the surface. The fact is that he is wasting about 6,000,000 tons of saleable coal per annum on his own boilers at the pit head. Of the 260,000,000 tons raised in Great

Britain per annum, $6\frac{3}{4}$ per cent. that is 17,500,000 tons, is used by the collieries themselves to provide the necessary power to work the pit. I have shown that the efficiency of colliery steam boiler plants is $55\frac{1}{2}$ per cent., and this could be raised to 70 per cent. by adopting scientific methods, that is, 3,625,000 tons of saleable coal is being wasted every year. But also a further 2,500,000 tons of saleable coal could be saved per annum if the collieries would burn on efficient lines some of their own refuse fuels now thrown away, and the total amount to be saved every year is therefore over 6,000,000 tons. I do not mean to infer that the colliery industry is much worse than any other, and I have shown Great Britain is wasting 20,000,000 tons of coal every year on stationary land boiler plants alone; but do let us have the elementary facts right I am, Sir, etc., DAVID BROWNLIE

Ealing, London
July 14, 1924

PERSONAL AND OTHER ITEMS

Dr. F. A. Freeth has been awarded the degree of D.Sc., of the University of Liverpool.

The late Mr. A. T. Hawes, J.P., a director of Brunner, Mond and Co., Ltd., and of the Castner-Kellner Alkali Co., Ltd., left estate of the gross value of £91,724, with net personalty £85,662.

Prof. J. S. S. Brame has been appointed Honorary Adviser to the Home Office and to the Board of Trade on petroleum questions. These posts were formerly held by the late Sir Boverton Redwood.

Brigadier-General Hon. F. C. Stanley, C.M.G., has resigned the chairmanship of the Associated Portland Cement Manufacturers, Ltd., the British Portland Cement Manufacturers, Ltd., and their allied companies.

The Italian Industrial Delegation now in London includes representatives of the paper making, artificial silk, textile, brass-founding, and hydro-electric industries.

Rockefeller Medical Fellowships have been awarded to, *inter alia*, R. K. Cannan, M.Sc., senior assistant in biochemistry, University College, London, and W. Robson, B.Sc., chemical assistant in the Therapeutics Department, University of Edinburgh.

Professor Sir Wm. J. Pope has been elected a foreign member of the Reale Accademia Nazionale dei Lincei of Rome in the Section of Physics and Chemistry and their Applications.

The King of the Belgians has appointed Dr. L. H. Baekeland, president of the American Chemical Society and the originator of bakelite, as commander of the Order of Leopold.

Amongst those who have been appointed to the Superior Committee of Commerce and Industry in France are the following, who are well-known in the chemical industry:—MM. Duchemin, Coignet, Donat, Agache, Aubrun, Bienaimé, Cavallier, de Peyerimhoff, Pinot, H. de Wendel.

In the will of the late Miss Marie Corelli, the novelist, directions are given for the formation of a perpetual trust to control and use her estate at Stratford-upon-Avon "for the benefit of distinguished persons visiting Stratford-upon-Avon from far countries . . . and as a meeting-place, as and when required by the President of the Royal Institution of Great Britain for the annual or provincial gatherings of scientists connected with that Institution."

The Annual Prize of the Société des Ingénieurs Civils de France has been awarded to Monsieur Clansel de Goussergnes, for his papers on the manufacture of electric iron and steel. Other awards include the Nozzo prize to Monsieur G. Claude for his paper on the synthesis of ammonia, and the Robin prize to MM. Chevenard and Poitevin, for their investigations on methods of research and control in metallurgy, and on light and ultra-light alloys.

Awards of research fellowships tenable at the Imperial College of Science and Technology during 1924–25 include the following names:—Gas Light and Coke Company's Research Fellowship of £200 (renewal) to F. R. Weston, A.R.C.S., for a continuation of his spectroscopic research on the flames of carbon monoxide and hydrogen and matters cognate thereto; Beit Research Fellowship. . Dr. W. E. Downey for research on photo-c.. problems, and to R. Quarendon, A.R.C.S., B.Sc work on the combustion of gases in nitrous oxide.

It is announced that the Woodrow Wilson Memorial fund, which is expected to reach $2,500,000, will be used to found a college in Georgia, in which the subjects taught will be those that interested the late President, *e.g.*, history, social and political economy. The humanities will be given an important position, but science will be taught, not with a view to make scientists, but as a part of the necessary equipment of educated persons and with particular regard to its history.

Mining Notes from Canada

The British Empire Steel Corporation has closed contracts for the delivery, during the year, of a further 300,000 tons of Wabana iron ore to iron masters in Germany and 110,000 with English firms. The present annual output is 700,000 tons.

The recently discovered bed of arsenical ore at Wellington, Yarmouth, Nova Scotia is being opened up. Analysis of some of the larger leads give 43·7 per cent. of metallic arsenic.

The United States Gypsum Co., of Chicago, is increasing operations at its quarry at Wentworth, Nova Scotia. This material will be shipped direct to Atlantic ports in U.S.A., replacing gypsum supplied from the interior of New York State.

Large seams of copper have been disco' New Rouyn district, of Northern Ontario, in proximity to railway transportation.

The Britannia mine, British Columbia, is operating again, shipping copper concentrates amounting to 200 t. per diem, with approximately 21·5 per cent. copper content.

REVIEWS

(1) Pulverised and Colloidal Fuel. By J. T. Dunn. Pp. 197. London: Ernest Benn Ltd., 1924. 25s. nett.

(2) The Utilisation of Low-Grade and Waste Fuel. By W. F. Goodrich. Pp. xix+368. London: Ernest Benn Ltd., 1924. 42s. nett.

(1) The matter contained in this book will not be new to those who have studied the literature of the subject which has emanated from America during recent years, but a very useful purpose is served by bringing together a judicious selection of matter within the covers of one volume. The author is to be congratulated upon the way in which he has done this, for his book might well serve as a model for any similar treatise upon a specialised technical subject.

The methods of grinding material such as coal to a particular degree of fineness at a minimum cost are of interest to technicians in a number of fields and these are described in some detail, but we are left with the impression that little is known as to how the design of plant should be altered to give a odu of different fineness. The author's statement, p. 65, that "the choice of a mill . . . may depend upon the required fineness," and that "if burners should be devised . . . to burn coarser material satisfactorily . . . one (mill) less efficient than another in producing extremely fine material might be more efficient or more economical in producing coarser stuff," does not lead us very far. Future developments in fuel technology will compel engineers to study this question more closely.

Fears have been expressed that the widespread adoption of pulverised fuel firing would lead to the ation of a nuisance by the deposition of dust. is interesting to note, therefore, the author's sonal experience that the dust is dispersed over ch a wide area that no trace of it can be found in the district immediately surrounding the installation. The further development of the processes described both in connexion with the combustion of low-grade solid fuels and in conjunction with the combustion of gas will be followed with very great interest.

(2) This book is characterised throughout by considered statements of the fuel situation which are calculated to counteract the influence of much loose thinking. In his enthusiasm for the utilisation of waste the author does not omit to show quite clearly the limitations of the quantities of waste fuel available. We do need to be reminded, at times, that the English peat deposits, for example, are of a different order of magnitude from the Morwell brown coal deposits, and that the utilisation of coke breeze has been developed so energetically within the gas industry that this fuel can be classified no longer as a waste product. Indeed, this volume will just its appearance if it leads to that accomplishment with other low-grade fuels which has been achieved already with coke breeze, a development which we are led to expect.

The fuel value of town's refuse, the recovery of fuel from ashes, briquetting, and the combustion or gasification of various low-grade materials are discussed in an exhaustive manner. The ground covered, however, is wider than indicated by the title and the excellent chapters upon steam boilers and upon furnaces and firing will prove to be a valuable guide to the generation of steam, either from best steam coal or from the contents of our dust bins.

There are a few examples, of awkward literary style and, perhaps, too many illustrations. Had some of the studies of rural life in Somerset, the Hawaiian seascape (Fig. 89), and some of the extracts from catalogues in chapter xiii. been omitted the publishers might have been able to offer the book at a price which would have attracted a wider circle of readers.

H. Hollings

Trattato di Chimica Fisica. Translated by Michele Giua from the Fourth American Edition by H. C. Jones. Pp. xxiii+731. Milan: Ulrico Hoepli, 1923. Price 56 lire.

This is the second Italian translation of the well-known text-book by the late professor of physical chemistry at the John Hopkin's University. The scope and treatment of the subject are approximately as in previous American editions, and the book, which is free from any but elementary mathematics, contains a large amount of matter laid out clearly and, on the whole, with good judgment. The historical method of exposition is largely employed.

Prof. Giua has considered it desirable to fill in a number of the more glaring gaps of the original version by inserting sections dealing with the classification of the elements, Walden's inversion, optical activity and molecular asymmetry, viscosity and chemical constitution, absorption of light, X-rays and crystalline structure, the colloidal state of matter, electro-syntheses of organic compounds, the chemical action of light, etc.

Even so, the attention paid to some of the subjects treated cannot be regarded as other than inadequate. For example, the kinetic theory of gases, including the derivation of the van der Waal's equation, occupies only two pages. Then, too, the question of isotopes surely deserves something more than dismissal in twenty lines, even although references are given to Aston's monograph and to an article in the *Nuovo Cimento*. No reference is made to the important subjects of hydrogen-ion concentration and its measurement; a large omission, this, at the present time.

In spite of these few blemishes, however, the book is well worthy of perusal and may be guaranteed not to lead the student very far astray. The translation is smooth and readable without furnishing justification for the saying "translators, traitors," and the paper, printing, and general finish are of the high standard expected of Hoepli publications. The rather long list of corrigenda tucked away, after the index, at the very end of the book, might well be accorded a more prominent position.

T. H. Pope

SCHWEFEL-UND STICKSTOFFSTUDIEN. By Dr. F. RASCHIG. Pp. vi + 310. Leipzig: Verlag Chemie G.m.b.H., 1924.

The veteran author of this book explains that the opportunity of writing it was afforded him by the sentence of five years' imprisonment, with a fine of 500 francs, passed on him by the French authorities in 1923, by reason of the discovery of two unsurrendered locomotives on his works. He has made excellent use of his time, and the *New Pilgrim's Progress* which is before us renders us obliged to the powers for providing the author with leisure. Dr. Raschig, is known as an indefatigable experimenter and a bold, if somewhat rash, theoriser. His classical researches on the compounds of nitrogen and sulphur are of the greatest interest and technical value. Most of this work is hardly mentioned in the text-books, and it is very convenient to have it summarised in this way. The style is interesting, and the descriptions of the experiments so clear that the reviewer could not resist the repetition of some of them. The subjects dealt with include the action of nitrous acid and its salts on sulphurous acid and its salts, new oxides of nitrogen (all purely imaginary !), iodide of nitrogen, monochloramine, nitroxyl, sulphonic acids of hydroxylamine, polythionic acids, and others. The hypotheses on oxides of nitrogen and on the mechanism of the oxidation of ammonia are hardly likely to meet with assent, since they involve the negation of Avogadro's law, and are not supported by any valid experimental evidence, but the rest of the book is full of the most clever experiments and reasoning. There can be few chemists who are not interested in some of the subjects dealt with, and those who are not will become interested on reading the book.

J. R. PARTINGTON

JAHRBUCH DER ORGANISCHEN CHEMIE. By Dr. JULIUS SCHMIDT. Vol. X. Die Forschungsergebnisse und Fortschritte im Jahre. 1923. Pp. xvi + 284. Stuttgart: Wissenschaftliche Verlags gesellschaft M.B.H., 1924. Price, bound, 18 Goldmarks; paper, 15.50 Gm.

In consequence of the War the appearance of the Year-book of organic chemistry was interrupted and no issue was published after 1914, the last volume being No. VII. The author therefore intends to include in the two Vols. VIII and IX still lacking reports for the intervening eight years, so that the Year-book will then form a continuous series up to the present date.

The author's object has been, as formerly, to give a brief summary of the more important contributions to organic chemistry and, with the object of covering a wider area of experimental work, to curtail or omit some of the theories and generalisations of less interest. He points out that owing to the development of biochemistry in recent years it has become necessary to include such subjects as hormones, enzyme chemistry, and the relation between structure and physiological action. Very short chapters on these subjects are to be found at the end of the book.

So far as one can judge from the large mass of material which occupies something like 270 pages of print, few of the more outstanding researches of the year have been overlooked, although it must be admitted that certain foreign contributions have not received the attention which has been accorded to some of lesser moment of German origin. This is perhaps only natural. None the less the work has been carried through with German thoroughness, and forms a valuable book of reference. It is arranged in accordance with the usual classification; it is well printed, with a good subject and author index, a bibliography of German publications for 1923, and a few short obituary notices of chemists who have died during the year.

J. B. COHEN

REPORT

REPORT ON THE COMMERCIAL AND INDUSTRIAL SITUATION IN HUNGARY, FEBRUARY, 1924. By R. J. E. HUMPHREYS, Commercial Secretary, Budapest. Department of Overseas Trade. Pp. 48. H.M. Stationery Office, 1924. Price 1s. 6d.

Since the last report was issued (*cf. Chem. and Ind.*, 1923, 859) Hungary has passed through great difficulties, and it seemed at one time that a complete collapse of the country must occur. Loans, however, were floated in Great Britain and Italy and the period was tided over, a good harvest strengthening the feeling of optimism which was produced.

The country is essentially agricultural, about one half of the population being employed on the land. Exports of cereals, peas, beans, etc. in 1923 totalled 395,240 t., and of fruit, vegetables, etc., 146,718 tons. Wines are exported, principally to Austria and Czechoslovakia, but this trade has decreased very greatly, compared with the previous year. The iron and engineering industries were developed to be self-contained in the former monarchy, but now have to depend for raw materials on importation, and also have to meet competition from Germany and Czechoslovakia in all their markets. Brown coal was mined to the extent of $7\frac{1}{2}$ million tons, but 775,000 t. of hard coal had to be imported. Textile industries made great progress during the year.

Although there was an improvement in industry and production in 1923, there was a falling off in the imports of manufactured goods, largely owing to legislative restrictions. Imports into Hungary in 1923 totalled 3,754,000 t., and exports 1,209,000 t. This adverse balance is much less than that of previous years. Imports of fuels, ores, and animal products increased; the principal articles showing increased export were agricultural produce. Imports from Great Britain decreased, largely owing to the reduction in the textile trade, but exports to this country, by reason of a considerable increase in the sales of sugar and chilled poultry, almost doubled.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Beet-Sugar Factories

Answering Mr. Baker, Mr. W. R. Smith stated that there were at present two beet-sugar factories in this country, one at Cantley in Norfolk, and one at Kelham, in Nottinghamshire. During the last manufacturing season—lasting from October to December—Cantley employed 795 men and produced 8957 tons of white sugar, whilst Kelham employed 433 men and produced 4322 t. of white sugar At present 251 men were employed at Cantley and 83 at Kelham. A third factory was under construction at Colwick, near Nottingham, and was expected to be ready in time for the next manufacturing season. -- (July. 8.)

Income-Tax on Research Fellowships

During the debate in Committee on the Finance Bill, Sir G. Butler, of Cambridge University moved a new clause exempting from income-tax a studentship or fellowship granted by a trust to a person exclusively for the purpose of his pursuing research studies under the auspices of any university in Great Britain. Mr Graham in resisting the new clause, said that already a very large measure of exemption from income-tax was given in that direction. The logical position pointed to the limitation of the concession to its present extent. The remedy lay in larger grants to the universities. On a division the clause was rejected by 185 votes to 100 (July. 10).

Dangerous Drugs

Answering Captain W. Benn, Mr. Henderson said the imports of opium by firms licensed under the Dangerous Drugs Acts was 125,833 lb. in 1923. The amount of morphine and its salts manufactured in 1923 was 254,337 oz., of which 166,397 oz. was converted into heroin, codeine or other derivatives of opium, leaving a net total of 87,940 oz., of which 78,611 oz. was exported. The amount of heroin manufactured in 1923 was 11,575 oz., and the total export of heroin was 12,011 oz. The output of codeine in 1923 was 162,036 oz., of which 160,910 oz. was exported As codeine was not subject to the Dangerous Drugs Acts, its movements were not recorded after it leaves the manufacturers, and it was not therefore known whether any other amounts of codeine were exported during 1923 by persons other than the manufacturers. (July 14.)

COMPANY NEWS

ALLEN-LIVERSIDGE, LTD.

At the annual meeting it was stated that the new factory at Liverpool has been put in complete working order. Compressing stations will shortly be opened at Belfast and Manchester, a new factory in Glasgow, and negotiations are practically completed for a site at Southampton. Regarding the issue of shares, the directors were able to offer them to their own shareholders on such terms as represented a very acceptable bonus. The report was adopted.

BRITISH OXYGEN CO., LTD.

In moving the adoption of the report and accounts, Mr. E. B. Ellice-Clark, the chairman, stated that the net profit of the company showed an increase of £18,478, or 14 per cent., as compared with the previous year, this satisfactory result being due to improved and more economical methods of production and the installation of larger plants to cope with the increasing demand, owing in some measure to the reduction in prices. The further issue of 75,000 shares at par, whilst enabling the company to continue its development policy without depleting its reserves or the profits earned, would have the effect of maintaining its very strong liquid resources at their present satisfactory figure. Referring to the proposed capitalisation of £175,000 of the share premium account balance of £176,655, Mr. Ellice-Clark said this bonus distribution of 35 per cent. was made out of money subscribed by the shareholders and utilised in the development of the company's business, and not out of profits. It could not, therefore, be unfavourably criticised by labour protagonists or those who had profited by the company's enterprise in providing factories in so many industrial centres to meet the demand for oxygen.

WELSBACH LIGHT CO., LTD.

After crediting £23,897, the amount received in settlement of excess profits duty less taxes, the accounts for the year ended March 31 show a net profit of £24,397. For 1922–23, the net profit was £26,397, including profit on sale of investments and debenture stock redemption, together £18,092. The past year's profit includes £17,945 brought forward. The directors propose to pay a dividend of 5 per cent., less tax, and to transfer to general reserve £6480, including discount of £770 on debenture stock redeemed. A balance of £22,966 is carried forward, subject to income and corporation taxes. For the preceding year a dividend of 5 per cent., less tax, was paid, together with a bonus of 2½ per cent., less tax, whilst the transfer to general reserve amounted to £7520, being the discount on debenture stock redeemed.

UNITED LUBRICANTS, LTD.

An issue is about to be made on behalf of a company which has been formed under the title United Lubricants, with a share capital of £120,000, of which £100,000 is in 8 per cent. cumulative preference shares of £1 each, and £20,000 in the form of ordinary shares of 1s. each The whole of the preference shares, together with 50,000 of the ordinary, will be offered at par, each subscriber for two preference shares being entitled to take up one ordinary.

The company will acquire the whole of the issued shares of London Lubricants (1920), which itself is an amalgamation of six undertakings and controls several others. The business is that of refining, blending and manufacturing lubricating oils, greases and kindred products, while the undertaking is said to number among its customers practically every Government department and the principal railway companies and municipalities throughout the country, in addition to engineering works and other consumers.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech.	£23 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	£45 per ton.
Powder	£47 per ton.
Acid Hydrochloric	3s. 9d.–6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.–£27 per ton makers' works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder	Spot £11 d/d., Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Methylated Spirit 64 o.p.—	
Industrial	3s. 1d.–3s. 5d. per gallon, according to quantity.
Mineralised	4s. 2d.–4s. 6d.
Potash Caustic	£30–£33 per ton.
Potass. Bichromate	5¾d. per lb.
Potass. Chlorate	3d.–4d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£3 10s per ton d/d.
Soda Caustic, solid	Spot lots delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals	£5 5s.–£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton, carr. paid.
Sod. Bichromate	4½d. per lb.
Sod. Bisulphite Powder 60/62%	£18–£19 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd 96%	£13 5s.–£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £14 10s. per ton d/d.
Sod. Sulphide cryst.	£9 per ton d/d.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	5¾d.–1s. 4d. per lb., according to quality.
Crimson	1s. 3d.–1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 11d. per lb.
Barytes	£3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide	3s. 9d. per lb.
Carbon Bisulphide	£24–£26 per ton according to quantity.
Carbon Black	7d. per lb. ex wharf. Dearer.
Carbon Tetrachloride	£56 per ton, drums free.
Chromium Oxide, green	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.–6½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	45s per cwt., barrels free.
Lead Hyposulphite	7½d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£15 10s. per ton f.o.r. London.
Sulphur	£10–£12 per ton, according to quality.
Sulphur Chloride	3d. per lb., carboys extra.
Thiocarbanilide	2s. 6d. per lb.
Vermilion, pale or deep	4s. 10d. per lb.
Zinc Sulphide	7½d.–1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£14 10s. per ton d/d. Demand active.
Grey	£19–£20 per ton. Fair demand
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.–£9 per ton, according to grade and locality. Demand below normal.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.–1s. per gall. 14/15° Tw.
Wood Creosote	2s. 7d. per gall. Unrefined.
Wood Naphtha—	
Miscible	5s per gall. 60% O.P. Market dull.
Solvent	5s. 6d. per gall. 40% O.P. Fairly good demand.
Wood Tar	£5 per ton.
Brown Sugar of Lead	£46 per ton.

TAR PRODUCTS

Prices in this section show some irregularity according to district. In the North East counties, for instance, anthracene, oil, solvent naphtha and naphthalenes are cheaper than in Lancashire or London. On the other hand, crude carbolic and creosote are dearer.

Acid Carbolic—	
Crystals	6½d.–6¾d. per lb. Fair inquiry.
Crude 60's	1s. 9d.–2s. per gall., according to district. Still quiet but slightly firmer.
Acid Cresylic, 97/99	2s 1d.–2s. 2d. per gall. Demand still good. Market firm.
Pale 95%	1s. 10d.–1s. 11d. per gall. Steady demand.
Dark	1s. 10d.–1s. 11d. per gall. Steady business.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	8½d.–9½d. per gall. Quiet.
Unstrained	7½d.–8½d. per gall.
Benzole—	
Crude 65's	10½d.–1s. per gall. ex works in tank wagons.
Standard Motor	1s. 4½d.–1s. 6d. per gall. ex works in tank wagons.
Pure	1s. 8½d.–1s. 10d. per gall. ex works in tank wagons.

Toluole—90%	1s. 5½d. per gall.
Pure	1s. 8d.—2s. per gall.
Xylol coml.	2s. 3d. per gall.
Pure	3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	9d.—9½d. per gall. Few inquiries.
Middle Oil Heavy	5½d.—6d. per gall. according to grade and district. Market weaker.
Standard Specification	6d.—8d. per gall.
Naphtha—	
Solvent 90/160	1s. 1d.—1s. 4d. per gall. according to district. Rather better inquiry.
Solvent 90/190	1s. 1d.—1s. 2d. Fair business passing.
Naphthalene Crude—	
Drained Creosote Salts	£4—£6 10s. Quiet.
Whizzed or hot pressed	£9 per ton. Little business.
Naphthalene—	
Crystals and Flaked	£13—£17 per ton in Yorkshire and London respectively. Market quiet.
Pitch, medium soft	52s. 6d.—57s. 6d. per ton f.a.s. for next season. Frequent inquiries.
Pyridine—90/160	19s.—20s. per gall. Market less firm.
Heavy	12s.—12s. 6d. Little business.

INTERMEDIATES AND DYES

There has been an appreciable increase in dyestuffs business during the past week. Prices remain constant.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 7d. per lb.
Acid H	4s. 3d. per lb. 100% basis d/d.
Acid Naphthionic	2s. 4d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 1d. per lb. Improved demand.
Acid Sulphanilic	9½d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	7¾d.—8½d. per lb. naked at works.
Aniline Salts	7¾d.—9d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 1d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 19/31° C.	4½d. per lb. Demand steady.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline	2s. 3d.—3s. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£85 per ton.
Diethylaniline	4s 9d. per lb. d/d., packages extra, returnable.
Dimethylaniline	2s. 4d. per lb. d/d. Drums extra.
Dinitrobenzene	9d. per lb. naked at works.
Dinitrochlorbenzol	£84 10s. per ton d/d.
Dinitrotoluene—48/50° C.	8d.—9d. per lb. naked at works.
66/68° C.	1s. 2d. per lb. naked at works.
Diphenylamine	3s. per lb. d/d
Monochlorbenzol	£63 per ton.
β Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 4½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 4d. per lb. d/d.
Nitrobenzene	5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	11¾d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis
m-Phenylene Diamine	4s. 2d. per lb. d/d.
p-Phenylene Diamine	10s. 3d. per lb. 100% basis d/d.
R. Salt	2s. 6d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 5d. per lb. 100% basis d/d.
o-Toluidine	8½d. per lb.
p-Toluidine	3s. 6d. per lb. naked at works.
m-Toluylene Diamine	4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P	£47 per ton.
Acid, Acetyl Salicylic	3s. 3d. per lb. Very heavy demand. Price firm.
Acid, Benzoic B.P.	3s. 6d. per lb. Larger supplies available. Market easier.
Acid, Boric B.P.	Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	19s.—21s. per lb.
Acid, Citric	1s. 6½d. per lb., less 5% for ton lots. Market extremely firm. Upward tendency.
Acid, Gallic	3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst.	7s. per lb. for 1 cwt. lots. Market firm; increasing demand.
Acid, Salicylic	1s. 6d—1s. 8d. per lb. Market still weak.
Acid, Tannic B.P.	3s. per lb. Market quiet.
Acid, Tartaric	1s. 1½d.—1s. 2d. per lb. less 5%. Better tone but not yet very active. Cheap offers of second hand parcels of foreign acid. Higher prices expected in view of firmness of raw materials.
Amidol	9s. per lb. d/d.
Acetanilide	2s. 3d. per lb. for quantity. Demand slow. Prices shaded to secure large orders.
Amidopyrin	13s. 3d. per lb. Neglected. Stocks low.
Ammon. Benzoate	3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	12s. 6d. per oz. for English make.
Barbitone	15s. per lb. Quiet market.
Benzonaphthol	5s. 3d. per lb. Small inquiry.
Bismuth Salts	A steady market. Prices according to quantity :
Bismuth Carbonate	12s. 9d.—14s. 9d. per lb.
,, Citrate	11s. 4d.—13s. 4d. ,,
,, Salicylate	10s. 2d.—12s. 2d. ,,
,, Subnitrate	10s. 9d.—12s. 9d. ,,
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides	Prices vary. Local stocks are being cleared and forward prices are higher. There are rumours of a coming shortage and higher prices in Germany.
Calcium Lactate	Demand active. Good English make can be had from 1s. 7d. to 2s. 6d. per lb.
Chloral Hydrate	3s. 10d. per lb. in jars. Carboys about 2d. less.
Chloroform	2s. per lb. for cwt. lots. Very steady
Creosote Carbonate	6s. 6d. per lb. Little demand.
Formaldehyde	£55 per ton, *ex* works. English make in casks. About 8s. per cwt. extra for carboys.

Glycerophosphates—	Fair business passing.
Calcium, soluble and citrate free ..	.. 7s. per lb.
Iron	.. 8s. 9d. per lb.
Magnesium ..	.. 9s. per lb.
Potassium, 50%	.. 3s. 6d. per lb.
Sodium, 50% ..	.. 2s. 6d. ,,
Guaiacol Carbonate	.. 11s. per lb. for cwt. lots. Slightly cheaper.
Hexamine ..	.. 3s. 6d. per lb. for English make. Market quiet and steady.
Homatropine Hydrobromide	.. 30s. per oz.
Hydrastine hydrochlor ..	English make offered at 120s. per oz.
Hydroquinone ..	.. 4s. 3d. per lb. in cwt. lots. Foreign make.
Hypophosphites—	
Calcium ..	.. 3s. 6d. per lb., for 28-lb. lots.
Potassium ..	.. 4s. 1d. per lb.
Sodium ..	.. 4s. ,,
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 5d. per lb., according to quantity.
Magnesium Carbonate—	
Light Commercial	.. £36 per ton net.
Magnesium Oxide—	
Light Commercial	.. £75 per ton, less 2½%.
Heavy Commercial	.. £26 per ton, less 2½%.
Heavy Pure ..	.. 2s.—2s. 2d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P	.. 52s. 6d. per lb. Weaker.
Synthetic ..	. 26s.—31s. per lb., according to quantity. English make. Strong demand.
Mercurials ..	.. Market firm and more active.
Red oxide ..	.. 5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	.. 3s. 6d.—3s. 7d. ,,
White precip. ..	.. 4s. 7d.—4s. 8d. ,,
Calomel ..	.. 3s. 11d.—4s. ,,
Methyl Salicylate	.. 1s. 11d.—2s. 1d. per lb. Tendency still in buyers' favour
Methyl Sulphonal	.. 26s. per lb.
Metol	.. 11s. per lb. British make.
Morphine and Salts	.. Reduced by 1s. to 1s. 3d. per oz.
Paraformaldehyde	.. 3s. per lb.
Paraldehyde .	.. 1s. 6d. per lb. in free bottles and cases.
Phenacetin ..	.. 6s.—6s. 3d. per lb. Price and demand steady.
Phenazone ..	.. 7s. 3d.—7s. 6d. per lb. Quiet.
Phenolphthalein .	.. 6s. 6d. per lb.
Potass. Bitartrate—	
99/100% (Cream of Tartar) ..	.. 88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate ..	.. 1s. 10d.—2s. 2d. per lb.
Potass. Iodide ..	.. 16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues heavy.
Potass. Metabisulphite ..	7½d. per lb., 1-cwt. kegs included.
Quinine Sulphate	. 2s. 3d. per oz., in 100 oz. tins. Very heavy demand.
Resorcin	. [illegible]s. 6d. per lb. Firmer.
Saccharin	.. 63s. per lb., in 50 lb. lots.
Salol	.. 3s. 6d.—3s. 11d. per lb.
Silver proteinate ..	.. 9s. 6d. per lb.
Sod. Benzoate, B.P	.. 2s. 9d. per lb. In quantity for British product.
Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity. Firm in common with other citrates.
Sod. Hyposulphite—	
Photographic ..	.. £13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	.. 16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	.. 75s.—82s. 6d. per cwt., according to quantity. Steady market, good demand.
Sod. Salicylate ..	.. Market more active. Powder 2s. 2d.—2s. 6d. per lb. Crystal at 2s. 4d.—2s. 8d. per lb. Flake 2s. 9d. per lb.
Sod. Sulphide—	
Pure recryst. ..	.. 10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Thymol	.. 16s. 6d. per lb. Very scarce indeed. Still rising.

PERFUMERY CHEMICALS

Acetophenone ..	.. 12s. 6d. per lb.
Aubepine	.. 14s. 6d. ,,
Amyl Acetate ..	.. 2s. 9d. ,,
Amyl Butyrate ..	.. 6s. 9d. ,,
Amyl Salicylate ..	.. 3s. 3d. ,,
Anethol (M.P. 21/22° C.)	4s. 6d. ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 10½d. ,,
Benzyl Alcohol free from Chlorine ..	.. 2s. 10½d. ,,
Benzaldehyde free from Chlorine ..	.. 3s. 6d. ,,
Benzyl Benzoate	.. 3s. 6d. ,,
Cinnamic Aldehyde Natural ..	.. 15s. 6d. ,,
Coumarin ..	.. 20s. ,,
Citronellol ..	.. 16s. ,,
Citral ..	.. 10s. ,,
Ethyl Cinnamate	.. 15s. ,,
Ethyl Phthalate ..	.. 3s. 3d. ,,
Eugenol	.. 10s. 6d. ,,
Geraniol (Palmarosa)	.. 35s. ,,
Geraniol	.. 11s.—18s. 6d. per lb.
Heliotropine ..	.. 7s. per lb.
Iso Eugenol ..	.. 15s. 9d. ,,
Linalol ex Bois de Rose ..	26s. ,,
Linalyl Acetate ..	.. 26s. ,,

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before Sept. 9 h, they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on July 24th.

I.—Applications

Boldy. Drying-machine. 16,054. July 4.

Cuylits. Process of preparing sintered materials. 15,951. July 2.

Koppers Coke Oven Co. Ltd. Apparatus for distilling mixtures of liquids. 15,801. July 1. (Ger., 5.7.23.)

Lockhart. Hydraulic separators etc. 15,832. July 1.

Marks (Darco Sales Corporation). Drying, burning, or revivifying material. 15,710. June 30.

Moll. Regenerative furnaces. 15,721. June 30.

Rigby. Drying apparatus. 15,791. July 1.

I.—Complete Specifications Accepted

1950 (1923). Flint. Evaporator apparatus. (217,945.)

7899 (1923). Dumont. *See* VII.

15,235 (1923). Jones. Automatic control of temperature in evaporating, drying, etc. (218,086.)

16,214 (1923). Mycock. Autoclaves, kiers, etc. (218,098.)

28,018 (1923). Lacy. Frame for use in solvent recovery by distillation. after extraction. (218,178.)

II.—Applications

Barrs. Briquetting material. 15,937. July 2.

Heath. Catalysts and production of liquid fuel. 15,764. July 1.

Josue. Fuel briquette. 15.725. June 30.

Marks (Darco Sales Corporation). 15,710. *See* I.

Tapping. Binder for briquetting fuels etc. 16,094. July 4.

Violini. Fuel briquette. 15,725. June 30.

Wallace. Production of decolorizing carbons. 15,955. July 2.

II.—Complete Specifications Accepted

35,023 (1922). Dederich (Ditmar). Treatment of hydrocarbons, particularly crude petroleum. (191,037.)

7865 (1923). Ashley, and Aldridge and Rankin, Ltd. Apparatus for making coal-gas. (217,969.)

8738 (1923). Tully. Manufacture of gas. (217,998.)

11,526 (1923). South Metropolitan Gas Co., Evans, and Stanier. Treating gases for removing carbon disulphide. (218,053.)

13,221 (1923). Praceiq. Preparation of pulverulent fuels for converting their ashes into hydraulic cements. (218,075.)

III.—Application

Coke and Maxted. 15,669. *See* XX.

III.—Complete Specifications Accepted

35,023 (1922). Dederich (Ditmar). *See* II.

10,003 (1923). Tyrer. Manufacture of phenol and phenolic bodies. (218,034.)

IV.—Applications

Farbenfabriken vorm. F. Bayer und Co. Manufacture of azo-dyestuffs. 16,138. July 4. (Ger., 18.7.23.)

Ransford (Cassella und Co). Manufacture of azotriphenylmethane dyes. 15,812. July 1.

V.—Application

Paschke, and Verein. Glanzstoff-Fabr. Method of recovering acetic acid from acetic solutions of acetyl cellulose. 16,021. July 3.

V.—Complete Specifications Accepted

8238 (1923). Cole Treating silk. (207,145.)

8994 (1923). Colas, and L'Alpha Soc. Anon. Treating liquor accruing from the lixiviation of vegetable matter. (200,482.)

1566 (1924). Chem. Fabr Griesheim-Elektron, and Wiss. Obtaining fibres from plants of the agave and yucca etc. (218,215.)

VI.—Application

Geigy Soc. Anon. Dyeing or printing textile fabrics etc. 15,993 July 3. (Ger., 23.7.23.)

VI.—Complete Specification Accepted

7933 (1923). Russell and Broomfield Filling, or dyeing and filling, of textile fabrics. (217,973.)

VII.—Applications

Casale. Catalytic synthesis of ammonia. 15,688. June 30

Crotogino, and Salzbergwerk Neu-Stassfurt. Process for recovery of salts. 16,024. July 3.

Dowson and Mason Gas Plant Co., Ltd. 15,979. *See* IX.

Paschke, and Verein. Glanzstoff-Fabr. 16,021. *See* V.

Rhenania Verein Chemischer Fabriken Akt.-Ges. Process of dissolving rocks etc. 15,846. July 1. (Ger., 10.7.23.)

VII.—Complete Specifications Accepted

7899 (1923). Dumont. Lime-kilns and other vertical kilns. (217,970.)

8204 (1923). Gjersoe. Producing metal oxides etc. (217,976.)

8576 (1923). Stewart, and Laporte, Ltd Manufacture of barium peroxide. (217,988.)

18,552 (1923). Shimadzu. Manufacture of lead suboxide intermingled with metallic lead powder. (218,119.)

VIII.—Complete Specification Accepted

19,071 (1923). Ohlsen. Producing impermeable strong and acid-proof tubes, bricks, etc. (218,127.)

IX.—Application

Dowson and Mason Gas Plant Co., Ltd., Maltby, and Paton. Gas-fired lime kilns. 15,979. July 3

IX.—Complete Specifications Accepted

7899 (1923). Dumont. *See* VII.

13,221 (1923). Praceiq. *See* II.

X.—Applications

Aarts. Extraction of metals from their oxides etc. 15,826. July 1. (Belgium, 28.7.23.)

Bosch. Blast furnaces, cupolas, etc. 15,924. July 2.

Bullen and Chopra. Manufacture of steels. 16,040. July 3.

Deutsch Luxemburgische Bergwerks- und Hutten Akt.-Ges. Hard alloy. 15,797. July 1. (Ger., 16.7.23.)

Fitzgerald. Means for recovoring gold etc. from diluto solutions. 15,772. July 1.
Holzapfel. Protection of metals by coating. 15,836. July 1.
Jascourt, Pattison, Rose, and Seal Co. Removal of rust and scale from metals. 15,692. June 30.
Marks (Glockenstahlwerke Akt.-Ges. Vorm. R. Lindenberg). Steel alloys. 15,708. June 30.
Marks (American Manganese Steel Co.). Heat treatment of manganese steel. 16,031. July 3.
Rhenania Verein. Chemischer Fabriken Akt.-Ges. 15,846. *See* VII.
Schaap. Heat treatment of iron. 15,823. July 1.
Vereinigte Aluminium-Werke Akt.-Ges. Aluminium alloys. 16,147. July 4. (Ger., 16.8.23.)

X.—Complete Specifications Accepted

1926 (1923). Loftus. Metallurgical furnaces. (217,943.)
4814 (1923). Berlin. Producing ferro-chrome and other ferrous alloys. (201,520.)
5705 (1923). Berlin. Producing rustless iron and steel. (202,952.)
7447 (1923). Thompson (Commercial Steel Co.). Steel. (217,963.)
8602 (1923). Marks (Kemet Laboratories, Inc.). Alloys. (217,991.)
8993 (1923.) Minerals Separation, Ltd. (Minerals Separation North American Corporation, Ltd.). Froth-flotation concentration of ores etc. (218,012.)

XI—Application

Prytherch. High-temperature resistance furnace. 16,079. July 4.

XII.—Applications

Fairweather (Kutsit Soap Co.). Soap compounds. 16,206. July 5.
Lever Bros., Ltd., and Tainsh. Manufacture of soap products etc. 15,815. July 1.
Taylor. Manufacture of margarine etc. 16,166. July 5

XII.—Complete Specification Accepted

22,447 (1923). Walton, and Tokalan, Ltd. Manufacture of oleo stearate of glyceryl. (218,154.)

XIII.—Applications

Baggaley. Sympathetic inks. 15,864. July 2.
Goldschmidt, Prill, and Wohl. Purification of pine tars and resin oils. 15,647. June 30. (Dantzig. 19.2.24.)
Witt. Preparation of a washable paint etc. 16,137. July 4. (Fr., 6.7.23.)

XIII.—Complete Specifications Accepted

5708 (1923). Armour. Purifying crude turpentine oils. (194,286.)
11,558 (1923). Bau. Synthetic resin. (218,054.)

XVI.—Application

Taylor. Treatment of soil. 16,047. July 4.

XVII.—Complete Specification Accepted

9004 (1923). Imray (Soc. of Chemical Industry in Basle). *See* XX.

XVIII.—Applications

Distilleries des Deux-Sevres (*formerly* Soc. Ricard, Allenet, et Cie.). Manufacture of absolute alcohol. 15,946. July 2. (Belgium, 6.7.23.)
Kahn. Manufacture and extraction of nitrogenous products from yeast etc. 16,139. July 4. (Fr., 7.7.23.)

XIX.—Applications

Aten and Lulofs. Pasteurising or sterilising liquids. 16,150. July 4.
Dixon. Purification of water etc. 15,717. July 1.
Kahn. Manufacture and extraction of nitrogenous products etc. from fish etc. 16,140. July 4. (Fr., 7.7.23.)
Taylor. 16,166. *See* XII.

XX.—Applications

Coke and Maxted. Oxidation of aromatic hydrocarbons. 15,669. June 30.
Distilleries des Deux-Sevres (*formerly* Soc. Ricard, Allenet, et Cie.). 15,946. *See* XVIII.
Dreyfus. Manufacture of aliphatic compounds. 15,936. July 2.

XX.—Complete Specifications Accepted

9004 (1923). Imray (Soc. of Chemical Industry in Basle). Manufacture of soluble acid calcium salts of inosite-phosphoric acid. (218,014.)
31,879 (1923). Wibaut. Manufacture of alkyl halides. (209,722.)

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number: *Argentina:* Steel, (A.X./1120); *Belgium:* Chemical products, ores, (48); *British India:* Steel, (East Indian Railway Co., 73-76, King William Street, London, E.C. 4); *Canada:* Hardware, (39); Cutlery, leather, (41); Brass, hardware, (42 and 43); *Chile*: Glass, (77); Iron wire, (78); Wallpaper, varnish, (79); *Cuba:* Artificial silks, (80); *Denmark:* Iron and steel, (52); *Italy:* Copra, (54); *Mexico:* Steel, (81); *Netherlands:* Sugar, (58); Chemicals, (62); *Poland:* Rubber tyres, (B.X./1064); *Rumania:* Asbestos, (65); *South Africa:* Steel, (A.X./1102); Hides, (B.X./1075); *United States:* Rubber, (73); Steel, (A.X./1098); China clay, (B.X./1074); *Uruguay:* Steel, (A.X./1121).

Metallurgical and Mining Notes from Canada

The ground has been broken for the erection of the first unit of the Dominion Alloy Steel Company at Sarnia, Ont., This portion of the plant will cost $1,500,000. The ultimate plans call for a $3,000,000 equipment.

The Carbon and Alloy Steel Company is opening a plant at Montrose, Ont. Mr. Wiles, of the firm of Carlisle and Wiles, Sheffield, Eng., has arrived to take charge.

The Canadian National Railway has placed an order for 56,000 tons of 85 and 100 pound steel rails with the British Empire Steel Corporation, Sydney, N.S., and 40,000 tons of similar rails with the Algoma Steel Co., Sault Ste Marie, Ont. This will represent between 350—400 miles of railway track. The same railway has placed orders for 20 very large locomotives with the Canadian Locomotive Co., Ltd., Kingston, Ont., and 30 powerful freight locomotives in Montreal.

The surplus zinc concentrates of the Sullivan Mine, southern British Columbia, are now being shipped to Antwerp for treatment. It is anticipated that over 100,000 t. will be exported during the year.

Much British capital is now invested in the gold and silver mines of North Ontario, and practically controls seven or eight properties.

JOURNAL of THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council of Pure and Applied Chemistry

which consists of Representatives from

The Chemical Society, the Society of Chemical Industry, the Association of British Chemical Manufacturers, the Institute of Chemistry, the Society of Public Analysts, the Faraday Society, the Institute of Brewing, the Society of Dyers and Colourists, the Society of Glass Technology, the Iron and Steel Institute, the Ceramic Society, the Institution of Gas Engineers, the Society of Leather Trade Chemists, the Royal Photographic Society, the Mineralogical Society, the Biochemical Society, the Institute of Metals, and the Royal Agricultural Society.

VOL. 43 NEW SERIES | LONDON, JULY 25, 1924 | NO. 30

EDITORIAL

THIS week we are honoured by being allowed to publish the Annual Reports of two important organisations which have made *Chemistry and Industry* their official Journal. With the Association of British Chemical Manufacturers the Society has long had a close, though an informal, connexion and at the present time the General Manager of the Association is the President of the Society, so that it will be safe to presume that co-operation between these two bodies will be easily maintained. The Association has been of great help to the Journal in many ways, and we are glad to acknowledge with perfect sincerity the consideration and friendly assistance always given, and we believe gladly given, whenever these were desired. In the work of co-ordinating the chemical activities of the country the Association must necessarily play a dominant part; the Society of Chemical Industry has made its main function the publication of information of value or of interest to applied chemists and others engaged in the chemical industry of the country. It will be seen from the Annual Report of the Association how many and how varied are the problems of chemical manufacturers which are common to the industry as a whole and can be conveniently solved in common. Our new President a few years ago gave up to party what was meant for mankind; this did not narrow his view of life nor was his political career so prolonged as to mould him in a definite crystalline form whose sharp edges and angular points hinder his utility in positions where some elasticity and power of accommodation are necessary. He becomes our President at a time of singular interest and some difficulty, but he has some unusual advantages in addition to his own abilities. He has the advantage of speaking at any time, subject of course to the views of his two Councils, for two closely allied organisations whose ultimate aims are identical, the furtherance of the interests of industrial chemistry. He has the further advantage of being able at any moment to secure the help of a very large number of chemists, using the word in a very wide sense indeed, who in the past have profited by his advice and encouragement and will in the future not be unmindful of this fact. It would be futile and indiscreet to set out the advantages which he possesses in an unusual quantity of common sense and so on; those who know him are well aware of these, and probably he knows himself sufficiently for this purpose.

* * *

The Institution of Chemical Engineers is a body of recent growth and its formation was regarded by many chemists as a rather unnecessary development. Both the Chemical Engineering Group and the Institution of Chemical Engineers have ideas and aspirations which are apt to conflict with the traditions and past history of chemical societies. The chemical engineers have been regarded as unorthodox in the worst sense of the word: but the chemical engineers are engineers with a chemical trend, and with chemical knowledge, not chemists. They have a different way of looking at the problems; some say they have brains of a different constitution or complexion. Whatever may be the truth about these matters the fact remains that chemical engineering is already an extremely complicated and important industry and will steadily become so to an even greater degree. It appears to us that it is to the advantage of engineers and of chemists that they shall work harmoniously together in promoting civilisation in the world. It is really of more importance that they should work together than that they should work harmoniously. A few discords make an agreeable feature in modern music, and many a happy family is enlivened by a few domestic jars. Not that there is any discordant element about the relations between chemical engineers and the Society of Chemical Industry or this *Journal*. Many important papers on chemical engineering have already been published in our columns, and if we can continue to receive such articles in the future the value of the *Journal* will increase greatly. Several of the papers of the Institution of Chemical Engineers have been of exceptional merit, well written, accurate and comprehen-

sive. The Institution has published some Transactions which have already become indispensable to industrial chemists, and the Society of Chemical Industry is extremely proud that the Institution is willing that a number of the Transactions should be published in these columns in pursuance of the arrangement mentioned in the Institution's Report. We look forward with considerable confidence to printing some of these in the course of the next few weeks, and are sure that the circulation of proofs of them beforehand will create considerable interest.

* * *

It has been widely proclaimed in the daily press that mercury has been partially converted into gold by a distinguished German man of science. No student of modern chemistry can now regard this feat as impossible; the conversion of one element into another is hourly taking place in many parts of the world and the artificial disintegration of elements has already been accomplished by certain physicists. Nevertheless, considerable caution or scepticism is still necessary when such startling phenomena as the artificial production of gold are announced. It is not that this cannot be done; surely within the next twenty years it will be done; it is merely that the operation will at first be extremely difficult, so difficult that its effect on the future supply of the noble metals need not disturb the present generation. The daily papers have within the last few days provided us with another announcement almost equally sensational and probably equally controversial. We allude to the letters to the *Daily Mail* by Sir William Pope and Professor Dixon, both of Cambridge, on the properties of a much advertised preparation known as Yadil. It is unfortunately difficult to make scientific tests of medicines. A few days ago an acquaintance of ours was afflicted with pains, a high temperature and other infallible symptoms of disease. After a couple of days in bed he recovered and was in normal health again, without the aid of any medicine. Had he taken a few cubic centimetres of Y's infallible cure or a limited number of X's all-healing pills, who can say he would not have equally recovered? In such a case the credulous would have ascribed the recovery to the drugs. But we cannot conveniently find two human beings with similar symptoms, similar powers of resistance, similar inherited tendencies and similar determinations to recover and treat one with the drug and leave the other to the care of Nature. The history of magic, astrology, spiritualism and some other occult studies shows how many possible causes may explain a particular fact and how illogical are the mental processes of those who are deeply imbued by a belief in the universal efficacy of a change in the moon, in telepathy, in talismans or in a dilute solution of simple organic compounds associated with a smell resembling that of garlic. Those who believe that the day they give a garden party is always wet, that it is unlucky to go to sea on a Friday or to go to the Court of Appeal with a decision of Mr. Justice A in their favour, can find plenty of evidence to support them. We are all credulous, even editors.

THE THEORY OF CO-ORDINATION AND THE LEWIS-LANGMUIR STRUCTURE OF THE ATOM

By C. J. BROCKMAN

(Contribution from the Chemical Laboratory of the University of Georgia)

The theoretical background of Werner's theory of co-ordination is practically the same to-day as it was when it was first announced. It has been shown that "anions such as chlorine can combine with metallic cations (Cr, Pt, Co, Cu, etc.) in two essentially different ways; they may be either in the inner sphere, attached by 'co-ordinative valencies,' or in the outer sphere of the molecule, attached by the ordinary type of bond." [1]

To explain complex compounds, Werner has postulated the "co-ordination number," which is the number of atoms or radicals in the first or inner zone.[2]

Beyond this and a host of experimental data there is very little theory concerning co-ordination compounds. T. M. Lowry[3] has developed some valuable ideas with reference to the Lewis-Langmuir structure. The Bohr theory of atomic structure has been correlated with co-ordination by N. V. Sidgwick.[4]

Several assumptions of the octet theory will be taken as the starting point, namely:—

1. Positive valence is determined by the number of electrons which an atom gives up.

2. Negative valence is determined by the number of electrons which an atom takes up.

3. Covalence is determined by the number of electrons which an atom shares with its neighbours.

4. Chemical combination is due to a "natural urge" which causes the atoms to take on or lose electrons so that the stable groupings of 2, 8, 18 or 32 electrons may be formed.

Lowry builds his theory on these four postulates and the following statement: "If one atom shares two electrons with another but contributes both electrons to the common stock instead of only one, it acquires a positive charge, whilst its neighbour (which has acquired a half-share in two electrons not originally belonging to it) becomes negatively charged." He then goes on to show that in platinic chloride the outer shell of 32 electrons is completed by drawing in six doublets from six chlorine ions. These six doublets are held in common by the platinum atom and the chlorine atoms and each element can claim an equal share in them. That is the platinum atom gains six electrons and each chlorine ion loses

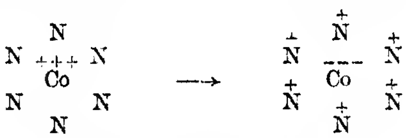
one, that is, the platinum atom is in the bivalent ion

$PtCl_6$ and the ion contains six neutral chlorine atoms held by covalencies, whilst the double negative charge is held by the platinum.

Lowry, furthermore, assumes that in the cobalt ammines each molecule of ammonia that is co-ordinated therefore acquires a positive charge like that of an ammonium ion, whilst the cobalt atom gains one electron. The effect is first to neutralise and then reverse the charge on the metal. Thus in the hexammines the charge on the cobalt is changed from Co^{+++} to Co^{---}, as follows :—



(The H atoms of the ammonia groups are omitted for the sake of simplicity.)

The theory now suggested differs from that of Lowry in that the co-ordination of the ammonia groups does not change the charge on the platinum ion. The accumulation of evidence points to this fact as a general rule, and that the third assumption above should be broadened to include the fact that a molecule may contribute a pair of electrons to the common stock to be shared by two atoms with the formation of a covalent bond. It will also be shown that when an anion is co-ordinated it contributes two electrons if monovalent, four if divalent etc. to the common stock to be shared by both atoms and so becomes covalently bound to the central atom ; in being so bound a monovalent ion reduces the positive charge on the central ion by one, while a divalent ion reduces the charge by two units.

Complexes Containing Platinum

The platinum atom having 24 electrons in its outer shell gives one electron to each of 4 chlorine atoms forming the compound $PtCl_4$, in which the platinum ion has 20 electrons in its outer shell and carries a positive charge of 4. The urge to complete the outer shell of the platinum ion to 32 electrons (that is the configuration of the outer shell of the next higher inert gas niton) is sufficiently strong to cause $6NH_3$ groups to be absorbed by the ion. Each NH_3 group contributes a pair of electrons (making 12 in all) to the outer shell of the platinum ion, so bringing the total number of electrons to 32. The compound so formed is well known as hexammine-platé chloride[5] $[Pt6NH_3]Cl_4$, in which there are 5 ions—namely, one $[\overset{++++}{Pt6NH_3}]$, and 4 chloridions.

If only 5 NH_3 groups are co-ordinated by the platinum ion the other two electrons needed to complete the shell of 32 are supplied by a chloridion. That is 5 NH_3, and one chlorine atom are co-ordinated ; but in co-ordinating the chlorine ion the platinum ion receives one electron which it originally gave to the chlorine to form the chloridion, together with another electron which it did not previously give to the chlorine atom ; the net result is that the positive charge on the platinum ion is reduced by one unit forming the complex compound chloro-pentammine-platé chloride $\left[Pt^{Cl}_{5NH_3}\right]Cl_3$, in which only three chloridions are known to be present.

In the compound dichloro-tetrammine-platé chloride $\left[Pt^{2Cl}_{4NH_3}\right]Cl_2$ the platinum ion receives 8 electrons from $4NH_3$ groups and 4 more from 2 chloridions, and completes its shell of 32 electrons. The co-ordination of the 2 chloridions decreases the positive charge of the central ion from 4 to 2, so that only half of the chlorine in the compound is present as chloridions.

This scheme may be followed through to the compound tetrachloro-diammine-platinum $\left[Pt^{2NH_3}_{4Cl}\right]$ which is a non-electrolyte. The four positive charges on the platinum ion have been entirely neutralised by the 4 negative charges in the co-ordination of the 4 chloridions. To complete its shell of 32 electrons the platinum ion in potassium pentachloro-ammine platéate $\left[Pt^{NH_3}_{5Cl}\right]K$ receives 2 electrons from the NH_3 group and 10 from the chloridions, together with 5 negative charges which not only neutralise the 4 positive charges on the platinum ion, but leave an excess of one negative charge on the platinum. It is this one negative charge which accommodates the potassium ion.

If no ammonia molecules are available for co-ordination as is the case when platinic chloride is treated with a solution of potassium chloride, the platinum ion co-ordinates 6 chloridions to complete its shell of 32 electrons but also receives 6 negative charges which leave the platinum ion with an excess of two negative charges so that the two potassium ions can be accommodated to form potassium hexachloro-platéate (potassium chloroplatinate) $[Pt4Cl]K_2$.

The fact that the halogen atoms inside the brackets are co-ordinatively attached to the platinum atom is proven by the fact that they cannot be present as halogen ions since they are not precipitated by the addition of silver nitrate

One co-ordinated ammonia molecule may be replaced by a pyridine molecule as in $\left[Pt^{Py}_{5Cl}\right]K$. Two monovalent acid radicals may be replaced by one divalent radical as the carbonate or sulphate radical. This means that a divalent anion on co-ordination brings with it 4 electrons and two negative charges, as in $\left[Pt^{SO_4}_{4NH_3}\right]K_2$.

The platinous ion can also form complex compounds, but in this case the outer shell contains 30 instead of 32 electrons. Starting with platinous chloride in which the platinum ion has 22 electrons in its outer shell, the co-ordination of ammonia leads to the compound $[Pt4NH_3]Cl_2$ in which the charge

(5) See "Inorganic Complex Compounds," Schwarz-Bass, p. 25, Wiley, 1923.

on the platinum ion remains unchanged at 2. If only three ammonia molecules are co-ordinated the compound is $\left[Pt\genfrac{}{}{0pt}{}{Cl}{3NH_3}\right]Cl$ and the platinum ion has lost one positive charge by the co-ordination of one chloridion. Similarly we have the compounds

$$\left[Pt\genfrac{}{}{0pt}{}{2Cl}{2NH_3}\right] \;;\; \left[Pt\genfrac{}{}{0pt}{}{3Cl}{NH_3}\right]K \;;\; \left[Pt4Cl\right]K_2.$$

In any of the above compounds the chlorine as an ion or in the co-ordinated condition may be replaced by another member of the halogen family, by the cyanide or the thiocyanate group; two halogen atoms may be replaced by one divalent acid group.

Complexes Containing Cobalt

Much has been reported on the cobalt ammines, so that many of the series of these compounds are complete. The cobalt atom has 9 electrons in its outer shell, and responds to the urge to complete this shell to 18 electrons, which is the stable configuration of the next higher inert gas, krypton. The cobalt ammine-nitrites will be taken as typical examples. In cobalt nitrite the cobalt atom in becoming an ion gives three electrons, one to each nitro group, which leaves the cobalt ion with 6 electrons in its outer shell. The stable configuration of 18 is obtained by co-ordinating $6NH_3$ molecules to form hexammine-cobalti nitrite $[Co6NH_3](NO_2)_3$. Each NH_3 denotes a doublet toward the completion of the shell of 18 electrons and shares them with the cobalt ion. As the charge is not changed by this co-ordination, the cobalt ion still retains its positive charge of three.

If only $5NH_3$ groups are co-ordinated the shell of 18 electrons is obtained by co-ordinating one nitrite ion which loses its property as an ion, and so decreases the charge on the cobalt ion from three to two, forming nitro-pentammino-cobalti nitrite. By a similar process the following cobalti nitrites may be formulated —

$$\left[Co\genfrac{}{}{0pt}{}{NO_2}{5NH_3}\right](NO_2)_2 \;;\; \left[Co\genfrac{}{}{0pt}{}{2NO_2}{4NH_3}\right]NO_2 \;;\; \left[Co\genfrac{}{}{0pt}{}{3NO_2}{3NH_3}\right] \;;$$

$$\left[Co\genfrac{}{}{0pt}{}{4NO_2}{2NH_3}\right]K \;;\; \left[Co\genfrac{}{}{0pt}{}{5NO_2}{NH_3}\right]K_2 \;;\; \left[Co\,6NO_2\right]K_3$$

In the above compounds the NH_3 molecule may be replaced by a water molecule forming the following compounds :—

$$\left[Co\genfrac{}{}{0pt}{}{2H_2O}{4NH_3}\right]Cl_3 \;; \qquad \left[\begin{matrix} & 2Cl \\ Co & H_2O \\ & 3NH_3\end{matrix}\right]Cl \;;$$

$$\left[\begin{matrix} Cl \\ Co\,H_2O \\ 4NH_3\end{matrix}\right]Cl_2 \;; \qquad \left[\begin{matrix} Cl & & 2H_2O \\ & Co & \\ Br & & 4NH_3\end{matrix}\right]Br$$

in which the halogen atoms are interchangeable with each other and with the nitro group. Also two monovalent atoms may be replaced by a divalent acid radical as the C_2O_4, CO_3 or ethylendiamine groups to form compounds as

$$\left[\begin{matrix} Br & N_2O \\ & Co\,NH_3 \\ Br & en\end{matrix}\right]Br \;; \qquad \left[\begin{matrix} 2NH_3 \\ Co\,C_2O_4 \\ 2NO_2\end{matrix}\right]R \;;$$

$$\left[Co\genfrac{}{}{0pt}{}{C_2O_4}{4NH_3}\right]X \;; \qquad \left[Co\genfrac{}{}{0pt}{}{CO_3}{4NH_3}\right]X.$$

Then, too, one NH_3 molecule may be replaced by a salt molecule or even an acid molecule as in

$$\left[\begin{matrix} & AgCNS \\ Co & \\ & 5NH_3\end{matrix}\right](NO_3)_3 \;; \qquad \left[\begin{matrix} & KNO_3 \\ Co & NO_2 \\ & 4NH_3\end{matrix}\right](NH_3)_2 \;;$$

$$\left[\begin{matrix} HCl \\ Co\ en_2 \\ Cl\end{matrix}\right]Cl_2 \;; \qquad \left[\begin{matrix} & AgCNS \\ Co & NO_2 \\ & 4NH_3\end{matrix}\right]\genfrac{}{}{0pt}{}{Cl}{NO_3} \;;$$

$$\left[\begin{matrix} AgCl \\ Co\ Cl \\ 4NH_3\end{matrix}\right]SO_4 \;; \qquad \left[\begin{matrix} & AgCl \\ & Cl \\ Co & H_2O \\ & 3NH_3\end{matrix}\right]SO_4.$$

The compound $K_4Co(CN)_6$ formulated on the above system as $[Co6CN]K_4$ is a cobaltous compound, in which the cobalt ion starts with 7 electrons in the outer shell, and adds 12 more from 6 cyanogen groups, making a shell of 19 electrons which configuration is unstable. The result is that the compound breaks down to $K_3Co(CN)_6$ according to the equation :—

$$2K_4Co(CN)_6 + 2HCl \longrightarrow 2K_3Co(CN)_6 + 2KCl + H_2.$$

This latter compound $[Co6CN]K_3$ is stablo, being the well-known potassium cobalti nitrite in which the cobaltic ion with 6 electrons in its outer shell adds 12 more, making the stable group of 18. Under ordinary conditions the salts of trivalent cobalt are unstable, but in complex compounds the trivalent cobalt compounds are the more stable, which substantiated the theory set forth above.

Complexes Containing Chromium

The chromium complexes follow the rules set out above except that in building up the outer shell of electrons the stable configuration of 18 is never attained; the process of co-ordination stops when the number of electrons in the outer shell reached 15. The following compounds bear out this fact. In hexammine-chromi thiocyanate the chromium ion has three electrons in the outer shell, and receives 12 more from the $6NH_3$ groups co-ordinated, bringing the total to 15. If a smaller number of NH_3 groups are co-ordinated a corresponding number of SCN groups are co-ordinated, as described above, so that the complexes of this series will be :—

$$[Cr\,6NH_3](SCN)_3 \;;\; \left[Cr\genfrac{}{}{0pt}{}{SCN}{5NH_3}\right](SCN)_2 \;;$$

$$\left[Cr\genfrac{}{}{0pt}{}{2SCN}{4NH_3}\right]SCN \;;\; \left[Cr\genfrac{}{}{0pt}{}{3SCN}{3NH_3}\right] \;;\; \left[Cr\genfrac{}{}{0pt}{}{4SCN}{2NH_3}\right]R \;;$$

$$\left[Cr\genfrac{}{}{0pt}{}{5SCN}{NH_3}\right]R_2 \;; \qquad [Cr6SCN]R_3.$$

The aquo-ammine chromi chlorides are well known, and their ionisation has been studied. All these compounds conform to the same scheme as do the thiocyanates. The aquo ammine chlorides of chromium are more stable than those of cobalt, and all but one of the series are known. They are rather sensitive to heat, for example $\left[Cr\genfrac{}{}{0pt}{}{H_2O}{5NH_3}\right]Cl_3$ loses its molecule of water when heated, with the result that one chloridion is co-ordinated, leaving only two chloridions in the complex $\left[Cr\genfrac{}{}{0pt}{}{Cl}{5NH_3}\right]Cl_2$.

Complexes Containing Iron

The ferric compounds are, as a rule, more stable than the ferrous compounds, but not always, which fact may be interpreted as follows: The co-ordinatively saturated atom of iron which has an outer shell of electrons approaching nearest to the stable krypton grouping of 18 electrons will form the most stable complex compound. Experimental data substantiate this fact. $K_4Fe(CN)_6$ is more stable than $K_3Fe(CN)_6$. In the former the iron atom is in the bivalent state, and so starts from 6 electrons in its outer shell, adds 12 more to make 18 in all; in the ferricyanide the iron being in the ferric state starts from 5 electrons, and by adding 12 more makes a shell of 17.

On the other hand, when iron is combined with three molecules of α-dipyridyl or 3 molecules of σ-phenanthroline trivalent, iron is only retained by very cautious work. An analysis of the electronic condition of these complexes shows that in the ferric state the 5 electrons in the outer shell receive 12 more (4 from each of three α-dipyridyl molecules etc.), making a shell of 17, while in the ferrous ion the 6 electrons add 12 more to make a shell of 18, the more stable grouping.

This analysis shows that a smaller number of electrons than is required to complete the next higher stable grouping is tolerated in the case of platinous compounds with good stability, also in some iron complexes, but a shortage seems to be preferred in the case of chromium complexes. But under no conditions is a stable compound formed when the number of electrons exceeds the stable grouping as in the case of the potassium cobaltous cyanide $K_4Co(CN)_6$.

Summary

1. The formation of co-ordinated complex compounds is explained as the result of a natural desire on the part of a metallic ion to complete its outer shell of electrons to that stable grouping assigned by the Lewis-Langmuir theory to the next higher inert gas.

2. By a sharing of electrons the co-ordinated atoms or ions lose their ionogenic properties and become covalently bound to the central atom.

Athens, Georgia, U.S.A.

THE WRITINGS OF GEBER

By Prof. J. R. PARTINGTON, M.B.E., D.Sc.

In the *Chemiker Zeitung* of June 28 Dr. Darmstaedter, of Munich, has a few remarks on "Geber Manuscripts" which are of interest. It will be remembered that I have consistently maintained that the reproduction of what this or that authority says on the matter, which is a method sometimes pursued, is of no value, and that further progess can only be made by the discovery of further unpublished material. This seems to be accepted by Darmstaedter, who has been looking into some of the *Latin* MSS. of Geber. As is usual with German scholars, he omits any mention of the English MSS., some of which are the oldest known. He states that the Paris BN 6514, which contains two copies of the *Summa*, and dates approximately to 1300, shows no appreciable difference from the printed texts. This was stated by Hoefer in 1842 (Histoire de la Chimie, 1842, Vol. I., p. 310), and by Berthelot (Chimie des Anciens, Vol. I., p. 344); I have confirmed it by inspection of the MSS. in question, and have also found that the text in BN 7156, of about the same date, is practically identical with that of BN 6514. This fact is not mentioned by Darmstaedter; Hoefer also refers to BN 6679, which I have not examined. The first statement of Darmstaedter is, therefore, common knowledge to all who have looked into this question and is far from new.

Darmstaedter next refers to a Bologna codex, Lat. 448 (756), early fifteenth century. This is a late MS., its date being approximately that of the earliest MSS. of the British Museum, to which I shall refer in a moment. This contains also the "Book on Furnaces of Geber," which usually accompanies the printed text of the *Summa*. The point to which Darmstaedter draws attention is that the explicit of the MS. states that it was translated in Anno Arabicum 1420 by Rodgerum Hyspalensem. He points out that 1420 leads to the date 1720, since the 7 is really a 4 (a well-known fact to those who have looked at early MSS.!), and since this would lead to an impossible date A.D., he assumes it to be 720, giving 1340 A.D.

He then remarks that Rodger Hispalensis (Rodger of Seville) is named as the translator of the "Book of Furnaces" in the Nurnburg text of 1541 and that of 1545. In the latter, which is the only one of the two I possess, the title reads: Gebri Arabis Philosophi solertissimi. Rerumque naturalium peritissimi, Liber Fornacum ad exercendam χημείαν pertinentium Interprete Rodogero Hispalensi (p. 184). The text of the 1541 edition is identical, as I satisfied myself some time ago. The Greek title is not without interest; the preface to the whole book is by Chrysogonus Polydorus, who mentions the statement of Suidas as to the origin of Chemistry, which he quotes in the original Greek, but says nothing of the Alexandrian alchemical MSS. of Zosimus, etc. I have found nothing in this preface which would give any hint as to the source of the MSS., but the treatise of Roger Bacon, and the *Correctorium* of Richard of England, also printed in the collection, make it not improbable that it was English.

The part played by Rodger of Seville is, of course, known to all who have looked into this matter. In the *Bibliotheque des Philosophes Chimiques, ou Recueil des Ouvres des auteurs les plus approuvez qui ont écrit de la pierre philosophale*, published in two volumes in Paris in 1672 and 1678, respectively, this name occurs. The first volume has the title: *Tome premier . . . par le Sieur S.D.E.M. a Paris chez Charles Angot, rue Saint Jacques au Lyon d'or M.DC.LXXII.* The translation of Geber is not in this, but in the second volume: *Tome Second qui contient cinq traitez . . . une Preface sur l' obscurité*

des Philosophes, et sur les Traitez de ce Tome, & leurs Auteurs . . . par le Sieur S. Docteur en Medicine . . . M.DC.LXXVIII. Both are by the same publisher. This *Sieur S.D.E.M.* is usually regarded as William Salmon, who published an English translation of Geber in 1692; in this reference is made to "the Author's House, at the Blue Balcony, by the Ditch-Side, near Holbourne Bridge, London." The second edition of the French work appeared in three volumes in 1741 and a fourth volume in 1754, enlarged by J. M(augin) D(e) R(ichebourg), with fatuous notes by the Abbe Lenglet du Fresnoy; the text of Geber's Summa is in volume 1. The French translations in the two editions are quite different, and Hoefer is in error in saying that the translation is that of the "Vatican edition" of the Latin text. The published Latin texts differ rather considerably, and may be divided roughly into two groups, represented by the Nurnburg text of 1541, referred to above, and the Rome text, published by Silber in c. 1530. Darmstaedter (Geber, p. 11), gives 1510–1520 as the date of this Vatican edition, which is clearly impossible since Pope Clement the Seventh is mentioned in it, and his dates are 1523–34 (Creighton, *History of the Papacy*, 1897, vol 6, pp. 203, 274, 341; during his pontificate the Vatican Library was considerably extended). I have had for some time notes of the principal variations, and it may save the time of Dr. Darmstaedter and others who appear to be going over the same ground, if I publish these elsewhere in the near future.

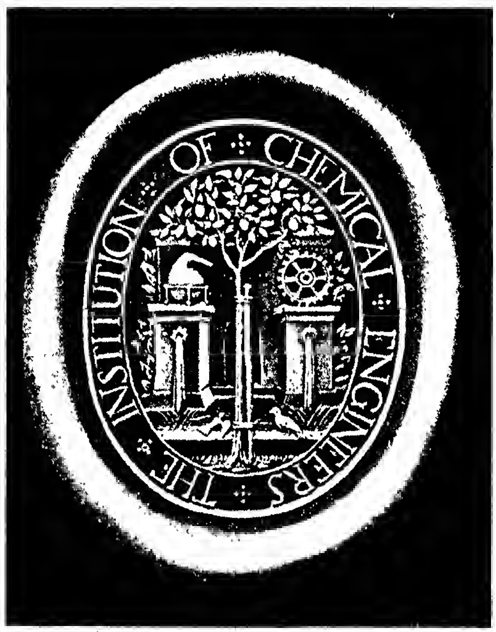
In the 1678 edition of the *Bibliotheque des Philosophes Chimiques* (which I do not think need be by Salmon), on the (unpaged) folio ã vi of the preface, the editor says: "Il n'y a pas aussi a douter qu'il ne l'ait écrit en Arabe, puisque mesme lá Livre qu'il a fait des Fourneaux a esté traduit d'Arabe en Latin par Roger de Seville." The editor of this edition also gives a useful list of variant readings of different editions of the printed text, which will be of use to those who have not made lists of their own. He refers to an edition published at Lyons in octavo, "dont le premiere feuille estoit déchirée." No edition of Lyons is known to me; perhaps the editor has mistaken Horn's edition of 1668, published at Leyden (Lugduni Batavorum) for one of Lyons (Lugduni), although he mentions this separately, and it is in 18mo, not 8vo.

Darmstaedter states that the Bolognese MS. proves that the "Book of Furnaces" existed, and was ascribed to Geber, at a date nearly as early as that of the earliest known copies of the "Summa."

I have been unable to find any particulars of Roger of Seville, but he is probably well known to Oriental scholars.

The MSS. of Geber in the British Museum which I have looked at are of no particular interest. The earliest of them is of the fifteenth century. Arundel 164, later fifteenth century, on paper, is fairly clear but much contracted. It begins "Totam nostram scientiam quae ex libris antiq. abbreviavimus" (fol. 131 vo), and ends "haec dicta sufficiant" (fol. 192 ro). It may be noted in passing that many MSS. have dictis instead of libris, and a fair idea of the contents may be got from these opening words. BN 7156 and 6514 have libris. Future students of Arundel 164 may be saved trouble if they note that on fol. 155 Geber's treatise breaks off suddenly at the end of Cap. lxxxvi. in the 1545 printed text, and Expositio Hermetis follows, which in turn is followed on fol. 157 ro by "Incipit liber divinitatis de origine lapidis," the Summa beginning again only on fol. 187 ro, and proceeding normally to fol. 192 ro. Arundel 164 contains several interesting treatises on alchemy, notably Albertus Magnus de Alchymia. Sloane 1091, of the fifteenth century, is less easy to read than Arundel 164, but its text of Geber is normal. It contains some English treatises, notably the letter of Raymund Lully to King Robert (fol. 97 ro.). Other MSS. are later than the printed texts. The Spanish MS. (Egerton) is quite recent, but may, of course, be a copy of an older MS. Sloane 1754, fifteenth century, contains several alchemical tracts, including the dialogue of Avicenna known as *de Anima* (fol. 50 vo), Liber Archillei physicus de corporibus et spiritibus (fol. 84 ro), Liber perfecti magisterii (fol. 95), Liber Rasis de 12 aq. precioss., etc. On fol. 136 is a sort of dictionary, including Arabic words ("Zarnet O=O arsenicum auripigmenti").

THE NEW SEAL OF THE INSTITUTION OF CHEMICAL ENGINEERS



INSTITUTION OF CHEMICAL ENGINEERS

Annual Report of the Council, July, 1924

1. Introductory

The Council has pleasure in submitting to the Corporate Members of the Institution an account of the work accomplished during the past year. The record is one of continued progress, which it is hoped will give the same satisfaction to the general body of members as to the Council.

2. Committees

At the first meeting of the Council held on Wednesday, July 4th, 1923, it was decided that four Committees should be created, namely:—

(*a*) General Purposes and Finance Committee.
(*b*) Education Committee.
(*c*) Publication Committee.
(*d*) Nomination Committee.

In view of the importance of the work of these Committees it was decided to enlist the co-operation of members of the Institution who were not members of Council. The Education Committee was also fortunate in having the assistance of a number of correspondents in different parts of the Empire. To all of these gentlemen the Council expresses its sincere thanks for the valuable services so generously and unselfishly given.

The Committees were constituted as follows:—

General Purposes and Finance Committee

Sir Arthur Duckham, K.C.B. (*chairman*), W. J. U. Woolcock (*vice-chairman*), J. Arthur Reavell, Jas. MacGregor, J. W. Hinchley, F. H. Rogers, C. S. Garland, H. Talbot, E. L. Randall.

Education Committee

C. S. Garland (*chairman*), Sir Alexander Gibb, G.B.E., C.B., Sir Frederic L. Nathan, K.B.E., W. Newton Drew, R. G. Browning, F. H. Rogers, J. W. Hinchley, W. J. Gee, E. W. Smith, F. R. Tunks, F. A. Greene.

Corresponding Members

Jas. MacLeod (Dunbartonshire), W. A. Fraymouth (Bhopal, Central India), W. G. Weaver (Cape Town), K. B. Quinan (South Africa), J. A. Wilkinson (Johannesburg), N. E. Rambush (Stockton-on-Tees), J. H. Young (Glasgow), A. Cottrell (Edinburgh).

Publication Committee

Wm. MacNab (*chairman*), J. W. Hinchley, C. S. Garland, A. R. Warnes, A. L. Booth, A. Baker, H. J. Pooley, M. W. Travers, E. A. Alliott, S. G. M. Ure, M. B. Donald.

Nomination Committee

J. Arthur Reavell (*chairman*), H. Talbot, W. B. Davidson, Sir Alexander Gibb, G.B.E., C.B., J. W. Hinchley, C. S. Garland, E. W. Smith, W. P. Joshua, C. J. Goodwin, F. A. Greene, E. A. Alliott.

3. Meetings

Since the last Annual Meeting the Council has held TEN Meetings, while the Committees have held meetings as follows:—

	Meetings.
General Purposes and Finance Committee	6
Education Committee	9
Publication Committee	7
Nomination Committee	6

4. Seal

The seal of the Institution, with the emblematic watering of the Tree of Knowledge from the Fountains of Chemistry and Engineering, is due to the happy inspiration of Mrs. J. W. Hinchley, who designed it, and to whom the Council feels itself greatly indebted.

The execution of the design by Mr. Cecil Thomas and the use of a new process by which this seal is affixed in gutta-percha to the certificate has produced a result of which the Council considers members may be justly proud.

Sir Arthur Duckham presented the Seal to the Institution as an enduring memento of his Presidency.

5. Official Journal

During the provisional life of the Institution, the question of the Journal *Chemistry and Industry* becoming the official organ of the Institution had been raised, and Mr. J. Arthur Reavell had agreed to negotiate with the Society of Chemical Industry on this subject. Subsequently a deputation, consisting of Mr. Reavell, Mr. Garland and the Honorary Secretary, met the Editor of *Chemistry and Industry* and a scheme approved by that deputation was accepted by the Council. The scheme included —

(*a*) A statement on the cover of the Journal that it was the official organ of the Institution of Chemical Engineers.

(*b*) That the Journal will print papers read before the Institution.

(*c*) That the Journal, by arrangement, will print "slip" proofs of papers read under the auspices of the Institution and hold sufficient copies to be included in the Annual Volume of Transactions. The cost of "setting-up" such papers will be borne by the Society of Chemical Industry, but the cost of printing and circulating "slip" proofs and printing additional copies for inclusion in its Annual Volume will be borne by the Institution.

It was understood that the Editor of *Chemistry and Industry* had the right to refuse matter which in his opinion would not be suitable for his Journal. In such case, "slip" proofs and printing for the Annual

Volume of Proceedings of the Institution will be carried out by the printers at the expense of the Institution.

6. British Empire Exhibition

The Institution has given active support to the British Empire Exhibition at Wembley. The Honorary Secretary was elected to represent the Institution on the Committee of the Chemical Section, and a sum of £25 was contributed to the cost. Mr. S. G. M. Ure carried out the work of planning the chemical engineering exhibit. This exhibit has attracted widespread attention, and the Council feels amply repaid for the efforts put forward.

7. Ramsay Memorial Laboratory

The raising of a fund for the establishment and equipment of a Chemical Engineering Laboratory in memory of Sir William Ramsay at University College, London, gave the Institution an opportunity of doing a definite practical work in the interests of chemical engineering education, and an appeal for funds resulted in the sum of £121 being handed over to the Ramsay Memorial Fund.

Mr. J. A. Reavell represents the Institution on the Chemical Engineering Committee of the Ramsay Memorial Laboratory, and the Council has great satisfaction in recording the establishment of this further school of Chemical Engineering in London.

8. American Institute of Chemical Engineers

The exchange of publications between the Institution and the American Institute of Chemical Engineers was agreed to and copies of the Transactions for 1921-22 of the American Institute of Chemical Engineers have been sent to our members.

9. Education Committee

During the year the Education Committee has been engaged upon a Memorandum on "The Training of a Chemical Engineer," and in draft form this is now being submitted to the heads of all the principal industrial firms of the country, with a view to obtaining opinions and criticisms, so that a final draft may be produced for approval by the Council prior to submission to the educational authorities for action.

The Council has prepared for the Department of Technology of the City and Guilds of London Institute a syllabus for examinations in Chemical Engineering which it is hoped will be held annually.

On the election of Professor E. C. Williams, first Ramsay Professor of Chemical Engineering, as a member of the Institution, he was co-opted as a member of the Education Committee.

10. Death of Mr. A. C. Flint

The Council reports, with the very greatest regret, the death on January, 1924, of Mr. A. C. Flint after an operation. The Council expressed their deep sorrow and sympathy with Mrs. Flint, and placed on record their great appreciation of his services to the Institution.

The Council also desires to record the very valuable services rendered by Mrs. Talbot, who voluntarily carried out the duties of assistant secretary for three months.

In conjunction with the Chemical Engineering Group the new assistant secretary was appointed after advertisement of the post and a careful and searching analysis of the replies. A joint Sub-Committee of the Institution and the Chemical Engineering Group finally considered the applications and interviewed candidates, Mr. Cecil J. T. Mackie, the selected candidate, taking up his duties as assistant secretary at the beginning of June.

11. Resignation of Dr. Charles Carpenter as Vice-President of the Institution

Dr. Charles Carpenter tendered his resignation as Vice-President of the Institution in February, 1924, considerations of health compelling him to withdraw from practically all his public work.

The Council accepted this resignation with very great regret and conveyed to Dr. Carpenter its sympathy and appreciation of the reasons which compelled him to resign.

12. Ordinary Meetings

During the year on account of the difficulties encountered by a new Institution, few meetings have been held, the work of the Institution being mainly that of its Committees.

The undermentioned papers were read and aroused considerable interest at well-attended meetings of the Institution :—

June 8th, 1923.—Mr. T. C. Finlayson on "Industrial Oxygen."

November 14, 1923.—Mr. M. B. Donald, on (1) "A Study of the Absorption Tower," by M. B. Donald and C. W. Tyson. (2) "A Study of the Conditions of Constant Rate of Flow in Filter Presses," by M. B. Donald and R. D. Hunneman.

February 18th, 1924.—Mr. D. M. Newitt on "The Transport, Storage and Distribution of Hydrochloric Acid."

13. Balance-Sheet

The Balance-sheet for the accounting period, January 1st, 1923, to December 31st, 1923, is submitted herewith.

At the termination of the preceding accounting period there was a considerable contingent credit amounting to £766 4s. 6d. in respect of called and uncalled Guarantees.

In the Balance-sheet for the accountancy period under review, the Revenue Account shows that the receipts from income have amounted to £1372 8s. 2d., whilst the Expenditure has been £1201 15s. 10d., leaving a sum of £170 12s. 4d. to carry forward to the year 1924. Whilst the expenditure shown comprises to a small extent items of a non-recurring character, in relation to purchases and printing necessary in the starting of the Institution, these are offset by the fact that the entrance fees on the income side of the account are, for the members already enrolled, a non-recurring item. Life membership composition fees, however, have been capitalised, and the amount now standing to the credit of that item has been invested in War stock.

14. Membership

The following gentlemen have been elected Honorary Members of the Institution during the past year.

M. Paul Kestner (France).
Principe Gionori Conti (Italy).
Dr. R. F. Ruttan (Canada).
Professor W. K. Lewis (United States).
Professor F. G. Donnan, F.R.S.

On June 1st, 1924, the membership of the Institution was as follows :—

Honorary Members, 6 ; Members 119 ; Associate-members, 76 ; Graduates, 17 ; Students, 3 ; Total, 221.

The interest in the Institution continues to be maintained, and applications for membership have been received from all parts of the world.

On behalf of the Council,

F. H. Rogers
J. W. Hinchley

On behalf of the Council—
ARTHUR DUCKHAM, *President.*
C. S. GARLAND.
F. H. ROGERS, *Hon. Treasurer.*

REPORT OF THE AUDITORS TO THE MEMBERS OF THE INSTITUTION OF CHEMICAL ENGINEERS

We have audited the foregoing Balance Sheet dated the 31st December, 1923, and have obtained all the information and explanations we have required. In our opinion, the Balance Sheet is properly drawn up so as to exhibit a true and correct view of the state of the Institute's affairs, according to the best of our information and the explanations given to us, and as shewn by the books of the Institution.

HUGHES & ALLEN,

67, Basinghall Street, London, E.C. 2. 12th February, 1924

SOCIETY OF CHEMICAL INDUSTRY
ANNUAL MEETING

Last week considerations of space prevented the insertion of some notes on the later items in the Liverpool programme. It must not be supposed that these were not as well organised and as interesting as the earlier items, and the delay in giving some account of them was, in the circumstances, unavoidable.

The United Alkali Co., Ltd., welcomed the Society at its Widnes works. Sir Max Muspratt, Bart., and other directors of the company, with an efficient staff of guides, showed the visitors round and explained the nature of the operations. The manufacture of ammonia from crude liquors and its oxidation to nitric acid interested them exceedingly, and it was striking to see the contrast between this modern development and the old, and yet successful, manufacture of bleaching powder. The great range of this company's operations is well known, and the skill shown in the manufacture of chlorine derivatives of organic bases is almost equally obvious. All those who visited this works were very grateful to the United Alkali Company for the hospitality and attention showed to them.

On the next day, July 10, a visit was paid to Port Sunlight. Time did not permit a tour round the whole town, but enough was seen to make us all wish to visit it some time in a leisurely manner. The magnificent hall in which we were entertained to dinner is spacious and interesting; the Hon. W. Hulme Lever acted as the principal host, Lord Leverhulme being obliged to return to London. Many of the members of the Society were much disappointed by the shortness of the day, twenty-four hours with a necessary deduction for sleep and meals, are inadequate for a place like Port Sunlight. One ought to spend a quiet six or eight hours looking at the pictures alone: they are a wonderful collection. Somehow or other means must be found on some future occasion for a more worthy inspection of them.

The visit to Lake Vyrnwy and the water supply of Liverpool was a fitting conclusion to the meeting. The mountains of Wales introduced a change of atmosphere which was mentally refreshing, although the actual temperature was almost tropical.

Next year the meeting will be at Leeds: in subsequent years no doubt other big cities will be visited. Liverpool will for long be an outstanding meeting; its huge numbers and the wonderful organisation of the various functions made it a striking success. It must be a great advantage to a city to have a happy Lord Mayor! Happiness is infectious, and at Liverpool we all caught some slight measure of the abnormal geniality characteristic of its Lord Mayor. It will never be possible to eclipse the Liverpool meeting, but in other ways and for other reasons the future meetings will also attain great success. Some cities and towns will strike different chords; in its way Liverpool was unique; other meetings will be unique in other ways, and we look forward to a long succession of pleasant meetings each with a charm of its own.

THE "RUTHS" STEAM ACCUMULATOR

(From a Correspondent)

One of the most remarkable developments in connexion with steam and power practice, of very particular interest to the chemical and allied industries, is the "Ruths" steam accumulator, the invention of Dr. Johannes Ruth, of Stockholm. The first patents were taken out in 1913, 165 patents being held by the end of 1921 whilst 214 further applications are pending, distributed amongst every civilized country. Also, we are given to understand over 150 installations are already at work on the Continent, and it will be remembered that Dr. Ruths delivered a paper on the subject at the recent World Power Conference at Wembley. The principle of accumulating or storing exhaust steam to a partial extent has, of course, already been used for many years past, such as for example without the use of water by merely passing it into an empty boiler or container, for immediate use to a low pressure steam turbine in the case of non-condensing colliery winding or rolling mill engines. Also, the principle of blowing exhaust steam into water in a container and re-evaporating the water has long been known to engineers and physicists, as in the Rateau accumulator and Druitt Halpin's feed water accumulator.

But Dr. Ruths set himself to use the principle of the accumulation of steam in water on the entirely different and much more important lines, of an essential part of the steam boiler plant so as to revolutionise the generation of steam in the boiler. He has been engaged for many years on research work concerning the intricate theoretical problems of the storage of steam in heated water, for details of which the original literature must be consulted. It is claimed that as a result of these investigations complete practical success has now been attained, and we are informed that accumulators with a storage capacity, which must be very large if success is to be obtained, of 25,000—70,000 lb. of steam are already in operation.

The general advantage from the point of view of the average chemical works, for example, is the extremely important one that the boiler plant can be kept running at a steady steam output and pressure all the time, whilst the steam is stored into the accumulator and delivered to the works exactly as required. Take, for example, a works with 5 Lancashire boilers. If the demand for steam was absolutely steady, say, at the rate of 22,500 lb. per hour, then 3 boilers would do, and they could always be run at the highest efficiency with a steady fuel feed and draught conditions and exactly the right size of feed water economisers and superheaters. In practice, especially in a chemical works, the demand fluctuates over wide limits, say, 15,000—37,500 lb. per hour, consequently 5 boilers have to be kept in operation instead of 3, in spite of the fact for the greater part of the time 2 or 3 boilers would do the work. This means a heavy drop in the efficiency of the steam generation for various reasons, including much greater radiation loss, and increased capital cost. The Ruths accumulator is essentially an apparatus which is added

to the boiler plant in such a way that in the above case the 3 boilers only can operate continuously at 22,500 lb. steam output, storing the excess in the accumulator which supplies automatically to the works any desired amount, even outside the range of 15,000—37,500 lb. per hour, without affecting the steam generation plant. That is to say the accumulator plays the same part in the equipment of the boiler plant as the flywheel in the steam or other engine, acting as a reservoir of energy.

The accumulator consists essentially of a large cylindrical container, generally horizontal, with hemispherical ends very like in appearance to the old "egg-ended" externally fired steam boiler, but of much greater size, built up of steel plates, which is almost full of water, to 90·95 per cent. of the total capacity, and covered with insulating material.

The steam from the boilers is admitted through a main provided with two non-return valves and this pipe passes along inside the accumulator almost the full length. To this steam main, which is under the surface of the water, is attached a considerable number, a typical installation being 16, of branch pipes leading downwards into wide mouth distribution nozzles which go almost to the bottom of the water. That is to say, the steam from the boiler is split up amongst a large number of nozzles and is mixed very rapidly and intimately with the water content of the accumulator. The steam passes out through a delivery pipe, and the whole is arranged to be perfectly automatic, any desired amount of steam passing out with a steady inlet from the boiler.

The principle of the steam accumulator would also appear to foreshadow a radical alteration in the design of the steam boiler. The ordinary "Lancashire" boiler, for example, in which by far the greater amount of steam in Great Britain is produced, acts first as a steam generator, that is an appliance in which liquid (water) is converted into a gas (steam). But it also acts in the very important capacity of a steam accumulator, a large reserve of steam always being stored above the water space, and one of the practical advantages of the cylindrical boiler as against the water tube type is this large reserve capacity, especially when the steam demand fluctuates as in most chemical works. Water-tube boilers have much less steam reserve, although they make up for this by increased rate of evaporation, but every steam boiler of ordinary design acts in a dual capacity, as a generator and an accumulator. The perfection of the separate steam accumulator means that we can now make the boiler for its true function only of a steam generator, that is merely a series of tubes with little or no steam space, and small water content, whilst all the steam is stored in the accumulator. Also the latter can be at lower pressure than the generator, so that for example a coil of pipes can be used for the latter at very great pressure, the steam passing through a reducing valve into the accumulator at a reasonable working pressure. A special form of accumulator can also be supplied to deliver superheated steam, which really consists of two containers on the regenerative principle on what may be termed one accumulator for superheated steam, and the other for latent heat.

THE ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS

ANNUAL REPORT

For the Year ending May 31st, 1924

(Slightly Abridged)

The Council has pleasure in presenting the Eighth Annual Report. The membership of the Association has increased from 135 to 152. In addition there are 11 Affiliated Associations, the same number as last year. The following have filled the respective offices during the year: President, Mr. R. G. Perry. Vice-Presidents, Sir John Brunner, Bart.; Dr. Charles Carpenter, C.B.E., M.Inst.C.E. Chairman, Sir Max Muspratt, Bart.: Vice-Chairman, Sir William Pearce; Treasurer, Mr. C. A. Hill, B.Sc., F.I.C. During the year there has been no change in the constitution of the Council. The Council records with satisfaction that the following members of the Council have been elected as Members of Parliament: Sir William Alexander, K.B.E., C.B., C.M.G., D.S.O., M.P.: Sir John Brunner, Bart, M.P.: and Dr. G. C. Clayton, C.B.E., F.I.C., M.P. The Council also desires to report that the General Manager, with their approval, has accepted nomination as President of the Society of Chemical Industry for the forthcoming year. In view of the visit of the Colonial Premiers to this country during the year, your Council thought it desirable to extend an invitation to them to be the guests of the Association with a view to discussing matters of mutual interest, and to visit representative works. Unfortunately, however, the Premiers, whilst anxious to accept the invitation, found it impossible to fit it in with their other arrangements.

British Empire Exhibition, 1924

The Council has organised what is believed to be the finest chemical exhibit which has ever been shown at any exhibition. The Chemical Hall at Wembley occupies 40,000 square feet, and is the largest section in the Palace of Industry. The aim which the Council had before it was to show to the world the present position of the industry and the progress recently made in the science of chemistry, such progress being the best guarantee for the stability of the industry. To this end, in addition to the industrial exhibit, and with the cordial co-operation of the Scientific Societies, the Council organised the Scientific Section, which has attracted such favourable notice. The Joint Scientific Committee, of which Dr. Levinstein acted as chairman, in addition to preparing the scientific exhibits, set up a Publications Committee, which took the responsibility of preparing literature to accompany the scientific exhibits. Of this committee Dr. E. F. Armstrong was chairman and also editor of the main publication, "Chemistry in the XX Century," a work which has achieved instantaneous success, and bids fair to carry all over the world the lesson which the Scientific Exhibit can best convey to those who visit it. In addition, a series of eight pamphlets on chemical subjects has been published, written in simple language for the general reader, and already

a large number of these have been sold to the public. The Council feels that members of the Association will desire to join them in offering hearty congratulations and grateful thanks to all who have co-operated in this successful enterprise. It is too early to attempt to estimate the total value of the Exhibition to the industry, but the Council is confident that the arrangements which it has made will be approved by the members and will be of lasting benefit in the improved status of Chemical Industry among other British industries.

Films for Chemical Industry

In furtherance of its policy of keeping the British Chemical Industry before the public, the Council has had prepared two films representing the manufacture and use of heavy chemicals and coal tar products respectively. The films will be exhibited throughout the country at public cinemas, and it is thought that by this means the public will be educated as to the importance of the chemical industry in national life.

Broadcasting

The general public have been further enlightened as to the importance of the industry through the medium of wireless telephony. On the 19 September, 1923, the General Manager spoke on the importance of "Applied Chemistry in Modern Life."

Market Reports

As announced last year, the system of contributing weekly Market Reports to *Chemistry & Industry*, the official organ of the Association, has been in operation throughout the year with marked appreciation and success. The Report is also made use of in other technical journals. The Council feels, however, that it is desirable that a larger number of members should contribute information for use in the compilation of these Reports, and has issued an appeal to all members inviting their co-operation. As in previous years, articles are being constantly written by the staff to the technical press with a view to keeping the industry well before the public.

Statistics

The arrangement with the Customs Authorities, announced last year, whereby statistics of imports of dutiable articles included in the Schedule to the Safeguarding of Industries Act are received monthly by the Association, has been in operation throughout the year, and in view of the utility of these statistics and the appreciation which has been expressed by the members the Council has decided to continue the arrangement throughout the forthcoming year.

Dyestuffs

The Council has been in frequent communication with the Board of Trade on the position brought about by the proposed agreement between the British Dyestuffs Corporation and the Interessen Gemeinschaft and other allied matters. The business of the Council is to develop chemical industry in this country and to safeguard the interests of all its members. It has endeavoured to do this in all the advice which it has given to the Government. At the time of preparing this Report it appears unlikely that the agreement will be ratified until the dyestuffs branch of chemical industry has been reorganised. In such a reorganisation the Council believes the members would desire it to take part, and the Council is willing at all times to give any possible assistance. The importation of certain British dyestuffs into Italy has been the subject of negotiations between the Governments of the two countries. An agreement has now been made to permit of the importation of British vat and gallocyanine dyes into Italy free of duty provided they are accompanied by a certificate of origin signed by the General Manager of the Association. The Council considered the proposal to establish a British textile school in China, and on the recommendation of Group IX appointed Mr. S. Whetmore of the British Dyestuffs Corporation to represent the Group on the General Committee.

Safeguarding of Industries Act

During the year only three appeals have been heard by the Referee under this Act. In the Rochelle Salt case the Referee held that Rochelle Salt was rightly included in the list as a fine chemical. Formaldehyde was removed from the list, but sodium formaldehyde sulphoxylate and zinc formaldehyde sulphoxylate were held to be rightly included on the ground they were synthetic organic chemicals.

Alcohol

It was announced at the last Annual Meeting that a number of concessions had been made by the Commissioners of Customs and Excise regarding the use of alcohol in chemical manufacture, and a memorandum on the general position was sent to all members in September last. At the request of the Commissioners the Council has since submitted a list of ethyl compounds in the manufacture of which the use of pure alcohol, denatured with 2 per cent. pure methyl alcohol, would be preferable to industrial spirit, and has suggested a conference between the Government chemists and representatives of the Association to discuss the evidence in support of the manufacturers' claim.

Translation of British Pharmacopœia into Chinese

The work of translating the British Pharmacopœia into Chinese is actively proceeding in Shanghai, and your Council is keeping in close touch with the progress being made. Criticisms and suggestions which have been made by the Council on the recommendation of Group VI have been adopted by the Translation Committee almost in their entirety.

Parliamentary Matters

Your Council has carefully watched legislation in so far as it affects chemical industry. Legislation with regard to Smoke Abatement, introduced into the House of Lords last year, has not become law owing to the change of Government, but it is anticipated that the question will again be raised, and any future developments will be carefully watched.

The Petroleum Bill, 1923, which had been introduced into the House of Lords to amend the Acts

of 1871 and 1879, was dropped by the Committee appointed to examine it.

It is anticipated that a Consolidated Factories Bill will be introduced shortly, and the Council is watching this matter.

Preservatives and Colouring Matters in Food

The Minister of Health has appointed a Committee to investigate the use of Preservatives and Colouring Matters in food, and your Council arranged for evidence to be given on behalf of the particular firms concerned.

Pitch, Standard Test for

In view of the varieties of the methods in use for testing Pitch, a desire was expressed that a standard method of testing Pitch which would be acceptable both to the producer and the user should be established. A Sub-Committee has been investigating the matter, but their labours are not yet complete.

Cresylic Creosote, Standard Test for

Difficulties having arisen between the producers and users of Cresylic Creosote as to the method of testing to be adopted for determining the quantity of Tar Acids present, a Sub-Committee was appointed to consider the matter. A method of testing has been adopted by the Association and submitted to the British Engineering Standards Association for adoption as the British Standard. The subject is at present being considered by that body.

Patent Law

The question of International Patent law has been a subject which has engaged the attention of your Council The necessity of having some central organisation to watch the interests of British manufacturers has resulted in the formation of the Trade Marks, Patents and Designs Federation, to which your Association has become affiliated. The Patents Committee has had several lengthy meetings to consider the International Industrial Property Convention of 1883, which regulates international relations in industrial property matters, and which is due to be revised at an official Conference to be held either this year or next. Representatives have also attended Conferences of the Federation on the same subject.

Rating of Machinery

The law relating to the Rating of Machinery in England differs from that in operation in Scotland, and an attempt was made in the last Parliament to unify the system, but, unfortunately, the Bill was not passed into law. A Departmental Committee has been set up to consider the question of the principle of the Rating of Machinery, and your Council, through the Federation of British Industries, has suggested that the basis for valuation of industry should be the structure of works plus the first motive power.

Census of Production

Members will be aware that a Census of Production is to be made on account of the current year. The President of the Association (Mr. R. G. Perry) has received and accepted an invitation from the President of the Board of Trade to serve on the Committee which has been appointed to deal with this subject.

Contracts

The unsatisfactory features of the Forms of Contracts issued by the Official and Public Bodies have been considered and representation made to the Federation of British Industries on the subject. As a result the Forms of Contract with Government Departments have been amended, but so far as Municipal Contracts are concerned the difficulties which members of the Association have experienced were not shared by those of other organisations, and in the circumstances it is felt that no useful action can be taken.

Unfair Competition

The question of Unfair Competition has been a subject which had engaged the attention of Trade organisations generally, and your Council is represented on a Committee set up by the Federation of British Industries to consider the subject and to draw up recommendations to the Government with a view to their being considered by Experts of the Economic Committee of the League of Nations at their meeting in Geneva. Sir H. Llewellyn Smith, Economic Advisor to the Government, has drawn up a Memorandum embodying the revised text of draft Articles of Convention on Unfair Competition, and these have been considered by the Committee referred to, and amended suggestions put forward in the interests of British manufacturers

Chemical Plant

Co-operation with the British Chemical Plant Manufacturers' Association has continued throughout the year, and as a result of representations made to your Council by the Plant Manufacturers, members have been asked as far as possible to place their orders for Chemical Plant with those firms who are members of the British Chemical Plant Manufacturers' Association.

Chemical Engineering, University College, London

Your Council received a request from University College, London, to appoint a representative on the Sub-Committee for Chemical Engineering, and is pleased to be able to report that Sir John Brunner, Bart., has agreed to represent the Association on that Sub-Committee.

Transport

The Transport Department has continued the policy of settlement by negotiation which has worked very satisfactorily. In August last a general reduction in railway rates was obtained to a level of 50 per cent. over the rates in operation on January 14, 1920, plus certain flat rate additions. The proposals of the Railway Companies as to the terms under which merchandise, other than dangerous goods,

would be accepted for conveyance at Owner's Risk, have been dealt with, and as the result of meetings with the railway companies only two or three points were left over for determination by the Railway Rates Tribunal. The conditions of Carriage for Damageable Goods, Merchandise by Passenger Train and Coal, Coke and Patent Fuel have also been settled. During last summer the railway companies submitted their proposed schedules of standard charges to the Rates Tribunal. Objection has been taken to the charges on the ground that they are too high. The subject will be discussed later with the Railway Companies, and if agreement cannot be reached the Tribunal will be asked to adjudicate. The Tribunal has commenced a public enquiry into the question of the net revenue of the railway companies, as provided for in Section 58 of the Railways Act, 1921. In order that Traders' interests may be safeguarded, an appeal for funds was made by the Traders' Co-ordinating Committee, and members of the Association have contributed an amount over £900.

The question of the retention of exceptional rates under Section 36 of the Railways Act has formed the subject of negotiations with the railway companies, with the result that a scheme has been drawn up which obviates the necessity for members giving particulars of each rate they require to be retained. The railways are taking a record of the rates actually used during a period of two years from January 1, 1924, and, subject to the provisions of the Act, all rates used during the two years, with a few minor exceptions, will be retained for use after the appointed day.

The liability of owners of private wagons to third parties for damage arising by reason of defects in such wagons has received careful attention. Counsel's opinion was obtained, and the view expressed that the railway companies were responsible to third parties if negligence could be proved against them. In some cases it would be difficult to say which party would be liable, and enquiries were therefore made to see if the risk could be covered by insurance. Your Council is pleased to be able to report that a policy has been arranged at the rate of 9d. per wagon per annum (minimum premium 20s. per annum), provided all wagons owned are insured. The amount covered is £10,000, including costs for any one accident, and £20,000, including costs in any one year. The charges made at the various ports throughout the kingdom have received the attention of your Council, and it is pleased to report that substantial modifications have been secured. Complaints of delay in the transit of tank wagons have been taken up with the railway companies concerned, and it is hoped that more satisfactory arrangements will be made by the railways to give generally better facilities for the transport of tank wagons. In addition to the foregoing matters, assistance has been given to various members in connexion with questions of rates, classification and sidings, which in many cases have resulted in concessions being obtained.

MAX MUSPRATT

FORTHCOMING EVENTS

Sept. 4 and 5. IRON AND STEEL INSTITUTE, Autumn Meeting at British Empire Exhibition, at 10.30 a.m. each day. (1) "Changes of Volume of Steels During Heat Treatment," by L. Aitchison and G. R. Woodvine. (2) "Investigations on the Herbert Pendulum Hardness Tester," by C. Benedicks and V. Christiansen. (3) "Effect of Changes in Total Carbon and in the Condition of Carbides on the Specific Resistance and on some Magnetic Properties of Steel," by E. D. Campbell and G. W. Whitney. (4) "Pickling: The Action of Acid on Iron and Steel, and the Diffusion of Hydrogen Through the Metal," by C. A. Edwards. (5) "Examination of Iron from Konarak," by J. N. Friend and W. E. Thorneycroft. (6) "On the Nature of High-Speed Steel," by M. A. Grossman and E. C. Bain. (7) "Improvements in the Brinell Test on Hardened Steel, including a New Method for Producing Hard Steel Balls," by A. Hultgren. (8) "Present Position of the Theories of the Hardening of Steel," by W. Rosenhain. (9) "Effect of Free Surfaces on the Plastic Deformation of Certain Metals," by F. C. Thompson and W. E. W. Millington.

Sept. 8 to 11. INSTITUTE OF METALS, Annual Autumn Meeting, to be opened at the Institution of Mechanical Engineers, when W. M. Corse, S.B., will deliver the third annual Autumn Lecture. On September 9 the morning will be devoted to reading and discussion of papers, followed by luncheon at the Connaught Rooms, Kingsway, the afternoon to be spent at the British Empire Exhibition. On September 10 further papers will be presented for discussion, the afternoon being devoted to visits to works. A reception will be held in the evening at the National Physical Laboratory, Teddington. A detailed programme will be issued in August.

Sept. 15. BRITISH EMPIRE EXHIBITION, Conferences of Engineering Societies, to be held in Conference Hall No. 4, at 10.30 a.m. Short papers on various Engineering Subjects will be read and discussed. Further information and tickets may be obtained from the Secretary, Society of Engineers, 17, Victoria Street, Westminster, S.W. 1.

SOCIETY OF CHEMICAL INDUSTRY

ANNUAL AUTUMN DINNER

The Annual Autumn Dinner of the Society will be held in London on Friday, November 14, 1924.

The place and hour of meeting will be intimated later along with other details.

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

The eighth volume of these Reports is now ready. The price of the book is 7s. 6d. to members of the Society, and 12s. 6d. to non-members, post free in each case.

A Member of the Society may purchase a set of Vols. II to VIII inclusive at the reduced price of £2 2s. 6d., and a Non-Member can procure a set at

CORRESPONDENCE

"A POINT OF ORDER"

Sir,—Professor Lowry's letter in your issue of July 11 raises the question whether the signs — and + should be used in any sense but that denoting "a deficit or a surplus of one electron."

I submit that historically the first use of these as electrical signs was to indicate the *kind* of electrification, and this therefore has priority over the quantitative application. It seems to me undesirable to restrict the significance of the older signs, and the onus of finding satisfactory new signs with a quantitative meaning such as Professor Lowry requires for his electro-covalent double bond rests with him. The dot and dash, already appropriated by physical chemists as appendages to ions, would probably serve his purpose.

As to the pairing of signs, it may be pointed out that in my original paper on the "Latent Polarities of Atoms" it was made quite clear, I believe, that the + and — signs were to be understood as being paired in a neutral molecule, one pair for each pair of mutually attached atoms between which a real or latent polarity distinction could be demonstrated. Thus tests for the polarities of atoms in vinyl ether lead to two separate expressions:

$$CH_2{=}CH{-}O\,Et \text{ and } CH_2{=}CH{-}O\,Et$$

and Professor Lowry now takes exception to such combined expressions as

$$CH_2{=}CH{-}O\,Et$$

which is simply an abbreviation for the more awkward forms,

$$CH_2{=}CH{-}O\,Et \quad \text{or} \quad CH_2{=}CH{-}O\,Et$$

No single alternative is free from objections; but the first, interpreted sympathetically, need give rise to no real confusion, and is to be preferred until a much better one has been invented.

Professor Lowry also discusses the phenyl group, of which a good deal has been heard lately. Kermack and Robinson (*Trans.*, 1922, **121**, 431) suggested that the benzene ring may functionate as a resonator rather than (I suppose) as a true key polarising group. Researches at Manchester tend to confirm this or what may in reality amount to the same thing in the long run—to show that the feeble electro-chemical character of this group renders its action wholly subservient to what Dr. Flürscheim has termed its "quantitative" effect or factor. This factor is manifested by the great strength of the bond by which it attaches itself to any atom and a consequent "weakening" and "tightening" alternately of the succeeding bonds and free or residual affinities. How, in spite of the apparently non-polar character of such disturbances, the apparently inconsistent behaviour of styrene, for example, towards polar reagents can be reduced to order, without the introduction of any new assumption, will shortly be demonstrated elsewhere.

In the hope of partially dispelling certain prevalent misunderstandings, may I be allowed to add the following remarks. The principle of induced alternate polarities does not supersede the three great factors in organic chemistry so ingeniously manipulated by Flürscheim in his classical papers, but claims recognition as a fourth factor (overlooked by Flürscheim in his calculations), and one as well worthy of consideration as the other three, often assuming the leading role. Next, it is not, as Professor Ingold erroneously assumes (*Trans.*, 1922, **125**, 93), a part of the disputed principle that when tervalent nitrogen and divalent carbon act in opposition the oxygen is invariably the key atom. The original statement (*Mem. Manchester Lit. and Phil. Soc.*, 1920, **64**, iii, 1) ran as follows—"Where they are in competition the influence of the oxygen *usually* appears greater than that of the nitrogen." (The italics are new.)

Lastly, it is no part of the principle that the piling up of homogeneously arranged key atoms necessarily enhances the effects initiated by one key atom. This fact was obvious from the beginning, and the carbonyl groups and the α-hydrogen atoms of carboxylic acids are incomparably less reactive than the corresponding aldehydes or ketones in spite of the additional oxygen atoms homogeneously arranged. As systems strive towards homogeneous arrangements, so minima of potential energy occur with complete "homogeneity" as with complete symmetry; maxima of potential energy are to be expected with some degree of heterogeneity.

Organic chemists will quickly recognise that the polar additive reactions of carbonyl in the complex

CH_3

$\quad\!\!>C{=}O$ are most in evidence, *not* when A is

A

an atom or group such as —Cl, —OH, —O Et, or —NH_2, tending to enhance the necessary induced positive character of the carbon atom, but when A is —H or —CO.X, which function in the opposite way from the carbonyl oxygen which confers on the carbon atom its distinctive character.—I am, Sir, etc.,

ARTHUR LAPWORTH

The University, Manchester
July 14, 1924

Sir,—In a recent letter entitled "A Point of Order" (this vol. p. 723) Professor Lowry protests against the practice of using plus and minus signs "in such a way that ions and molecules are not distinguished from one another." In the same letter Professor Lowry refers to me in a way which might suggest that I am an upholder of the custom of which he disapproves. I may, therefore, perhaps be allowed to make my position clear, and to say that, on the contrary, I entirely agree with him in his condemnation of the practice. The misunderstanding which led Professor Lowry to quote certain polar formulæ which I wrote at the Chemical Society is a very curious one, for it will be evident to anyone who reads the report of that discussion* (this vol.

* Despite some obvious misprints, *e.g.*, "a key position" for "key-positive,"

p. 665) that I was using the language employed by the principal advocates of the polarity theory merely for the purpose of showing to what fallacious results a fallacious theory can lead, and not in the least because I, myself, believed a word of it!

Every student of Organic Chemistry is aware that carbon valencies possess some attribute (of quality, or of amount) which can *alternate* along a chain. All are aware of the existance of an influence which manifests itself near certain groups, and may aptly be termed a "*polar*" influence. My own study of the numerous facts, and many discussions with my friends and co-workers, have, however, convinced me that the combination of these two ideas into a "theory of alternate polarities" (whether a general theory, or one relating to double bonds alone) is wrong. It is, I believe, a false combination of correct ideas, and, despite all the attractions of its simplicity, it is not, nor will any so elementary a generalisation turn out to be, the true solution of our difficulties.—I am, Sir, etc.,

CHRISTOPHER INGOLD

THE USE OF ALUMINIUM

Sir,—Answering the inquiry of Mr. Joseph Barnes on page 667 of your issue of June 27, as to how the idea originated that food cooked in aluminium is injurious to health, it should be remembered that the aluminium used in making pots and the like may in some cases contain metals other than aluminium, *e.g.* zinc or copper, added mainly to make the alloy work right. If zinc or copper dissolve off, there may be trouble, but the greatest care must be exercised in finding the facts in any particular case, for the illness reported may of course have quite other causes.—Yours, etc.,

JEROME ALEXANDER

July 11, 1924

SAFEGUARDING OF INDUSTRIES

Sir,—I have read with interest Sir William Pope's letter in your issue of the 13th ult., commenting on mine of May 2. As we have had each the opportunity of stating our views, I have no doubt Sir William will agree that no good purpose will be served by a lengthened correspondence, and that it will be sufficient to leave the issues raised to the consideration of your readers.—I am, Sir, etc.,

WM. E. KAY

PERSONAL AND OTHER ITEMS

The death has occurred of Dr. N. Lorenz, who will be remembered as the originator of a method of estimating nitrogen.

Dr. M. Benjamin, the editor of the publications of the U.S. National Museum, and an original member of the Society of Chemical Industry, has been made a knight of the Order of the Crown by the King of Italy, in recognition of his attainments in Science.

The German Dyestuffs Industry

According to a report by the U.S. Department of Commerce, the Italian dye market is practically under German control, and if the "cartel" and the British Dyestuffs Corporation complete an agreement, German interest in British dye markets will be important. The possibility of an agreement between Swiss dye interests and the "cartel" is discussed, and it is suggested that France can maintain "only a limited independence" of the "cartel," which appears to have been at work in Russia. Expansion of the "cartel" is limited, however, by the natural resources of Germany and costs must grow the more dependent Germany becomes on imported raw materials. The industry tends toward self-sufficiency, controlling power, mines and a states up to finished products. At present acti work is being carried out to find new applicati — (*Oil, Paint and Drug Rep., June* 30, 1924.)

COMPANY NEWS

MOND NICKEL CO., LTD.

Presiding at the tenth annual general meeti the Right Hon. Sir Alfred Mond referred to the death of Sir Edmund Walker, the late presider n the Bank of Commerce of Canada, who had r sented the firm in Canada for a great many and to the death of Mr. F. J. Bloomer, the manager at Clydach, who was connected with company since its first inception. A profit and lo account was published, for the first time, which showed a balance of profit of £276,457. Additions had been made during the year to mines and other properties in Canada of £104,926, which, except for £13,000 transferred from suspense account, represented expenditure during the year in Canada on construction at the Coniston Smelter, enlarged by the addition of a third unit, now in operation, and on special development work at one of the mines. The amount of £79,863 had been written off from special depreciation reserve, in respect of the value of the Canadian properties, leaving a net addition to the same of £25,062. Additions made to properties in the United Kingdom amounted to £224,712, which included £136,075 transferred from suspense account. The sum of £106,292 had been written off the property at Clydach. A balance still remained which would be allocated in due course.

The credit balance on profit and loss for the year was £276,457, £31,317 less than in the previous year, due to the low prices prevailing for the main products—nickel and copper sulphate—during the greater part of the year, the price now obtained for these being below pre-war value, although the costs of production were above the pre-war level. The same occurred with regard to copper, the prices being unduly depressed on account of close competition. The exchange fluctuations in the main export markets—France and Italy—made business very difficult. There was an increase of 47 per cent. in the tonnage of nickel sold. The use of nickel in non-ferrous alloys was continuing, and some of the big countries had substituted nickel coins for paper notes and silver coins of small denomination. The use of nickel was

rapidly growing, especially in America, and the company had established considerable works there and also associated itself with a concern which was beginning to market nickel utensils on a considerable scale. This company, being in its initial stages, was not producing anything towards the dividend of the company, but progress was being made, and it was hoped that in time it will be a valuable concern.

A good deal of the prejudice which existed in the past, and of the difficulties put in the way of the use of nickel owing to insufficient technical research, was being overcome by the company, which controlled production in all its stages.

Messrs. Henry Wiggins and Co. this year declared a dividend of 10 per cent. on the ordinary shares, free of tax, over a period of nine months, as against 4 per cent. over twelve months for the previous year. This concern was becoming a valuable asset to the Mond Nickel Co.

The accounts were passed and the following dividends were declared :—To the holders of the 500,000 cumulative preference shares and the 2,000,000 non-cumulative preference shares of £1 each, numbered 1 to 2,500,000 inclusive, in the capital of the company, a dividend of 7 per cent. per annum for the year ended April 30, 1924, including the interim dividend paid on March 3, 1924, and subject to the deduction of income-tax. To the holders of the 900,000 ordinary shares of £1 each, numbered 1 to 900,000 inclusive, a dividend of 2s 6d. per share, subject to deduction of income-tax, and including the interim dividend paid on March 3, 1924. On the motion of the Chairman, seconded by Mr. Robert Mond, J.P., the retiring directors (Dr. C. V. Corless, Viscount Erleigh, Sir Robert Hadfield, Bt., and Mr. Robert Mathias) were re-elected

REPORT

Annual Report of H.M. Chief Inspector of Factories and Workshops for the Year 1923. Pp 129. Cmd. 2165. H.M. Stationery Office, 1924. Price 3s.

The raw silk industry is in a very bad state owing to foreign competition and also to the rapid growth in the manufacture of artificial silk ; an artificial silk factory has been extended in Coventry and another large works has been opened in the Wigan district.

With trade in such an unsettled condition, new developments have been less numerous than usual in the Midlands. Perhaps the most striking are : the development of large electrical power stations ; also the introduction of the "Schoop" process of metal coating by a finely-divided spray of molten metal ; the manufacture of synthetic ammonia and nitrates ; new operations for purifying lead by a wet chemical process ; an electrolytic process for the manufacture of carbonate of lead, and the further development of the internal combustion marine engine. Production in the manufacture of stainless steel and rustless iron has made rapid strides, and many new developments are recorded.

The initial difficulties met with in the administration of the celluloid code are being gradually overcome, but some cases, particularly those relating to inward opening doors and the means of escape in the tenement factories in Sheffield, have not yet been satisfactorily settled. Many interests are involved and consequently the work is slow, but steady progress is being made to ensure compliance with the requirements. Trade depression and financial stringency have prevented more rapid progress.

Chemical Works.—Substantial compliance with the requirements of the Regulations has been secured without resort to a single prosecution. Mr. Brothers (Warrington), in whose district there are a large number of important works, reports that the manufacture of salt cake has now become almost a mere minor product. One case of arseniuretted hydrogen poisoning arose from the solution of zinc residue in sulphuric acid, with the escape of fumes into the workroom. Suppression of dust is the chief difficulty where certain materials are conveyed long distances, and economical forms of mechanical conveyance do not lend themselves readily to enclosure ; success has not yet been attained. No difficulty has been experienced in securing efficient illumination ; in fact there is rarely any deficiency found. As regards inflammable dust, it has been found necessary to have double air-tight glass covers for incandescent electric lamps about coal grinding plants for furnace firing by dust. Improved methods of dealing with dust are discussed at length.

The liability to an escape of a dangerous gas or fume which calls for the provision of respirators, etc., exists in 27 of the chemical works. In 19 of these 27 factories apparatus is kept of the definitely safe type where only outside air is breathed, but in many of these 19 works it is desired to retain the right to use an apparatus of the Tower or the Army Box Absorber or the self-contained Mines Rescue types. The monthly examination is regularly and methodically performed. There have been cases of gassing in chemical works during the year due to carbon monoxide, sulphur dioxide and to chlorine, but in no case was it due to a failure to observe the regulations. Certain types of self-contained breathing apparatus have been approved for use in mines by the Mines Department of the Board of Trade and, upon application being made for their use in chemical works, approval will be given. The precautions against inadvertent production of arseniuretted hydrogen are generally well observed, and wooden buckets and spades, copper or lead scoops and ladles are generally used for this purpose. In sulphate of ammonia plants a copper scoop is usually used. The provision of drenching water and eye wash bottles has been found with but few exceptions to be satisfactory.

Many applications for exemption were received from gas undertakings in respect of sulphate of ammonia and tar-dehydrating plants. Agreement has been come to with the National Gas Council as to the exemption to be given for sulphate of ammonia plants but not for tar plants. The danger of epitheliomatous ulceration from tar exists even in small works, and it is not desirable to give exemption from the necessity to provide suitable bath and washing accommodation. Eighteen certificates have been

granted during the year, mainly to permit the use of public baths instead of providing bath accommodation at the works.

The use of the plastic form of rubber mixed with lead oxide is increasing. By its use exemption from the requirements to provide exhaust ventilation and to have periodical medical examination of the workers follows automatically. The chief development that has been noted is the use of rubber solutions in the manufacture of *crêpe* soled tennis and similar shoes, which bring these works within the scope of the regulations. The trade has readily complied with the requirements, and the danger has been guarded against from the outset. The demand for this rubber solution has led to an extension in its manufacture. It is generally made in mechanical mixers, from which the danger of escaping fumes is limited and can be adequately met by maintaining a suitable ventilation.

The advantage of good natural lighting in works has also been realised, and a new method giving a good illumination towards the centre of wide buildings depends on light refraction. The idea appears to be to throw the light horizontally across the room, no matter in what direction it may fall upon the outside of the windows, by means of "prismatic glass," the surface of which, instead of being smooth, is ridged vertically at angles of 30° or 45° or 60°, whichever is preferred.

Exceptions to the general compliance with Statutory Welfare Orders are to be found in chrome dyeing, glass-bottle making, and in a less degree glass-bevelling. The bi-weekly inspection of fingers is difficult to observe in the large dyeworks by reason of the refusal of some of the operatives to submit to examination. The bi-weekly examination of the fingers has not only resulted in the discovery of septic wounds due to causes other than chrome, but has had the intended effect of eliminating men susceptible to chrome eczema and chrome ulceration from rooms in which chrome is used. In one factory where three chrome cases due to fluoride of chrome, which is not within the scope of the Order, had occurred in the printing of wool, the occupier consented to carry out the whole of the provisions of the Order in relation to this process.

Medical inspection inquiries among others, related to special incidence of lead poisoning in shipbreaking and in the manufacture of electric accumulators; visits to certain centres in Germany to see the effect on horsehair of low-pressure steam disinfection as a means of protection against anthrax; incidence of epitheliomatous ulceration among mule spinners from mineral oil and in the manufacture of arsenic compounds; the following up of the first definitely recorded cases in this country of manganese poisoning. Reference is also made in some detail to fatal poisoning from arseniuretted hydrogen gas, from fumes from melted cadmium, and from benzol; and to effects on health from new developments in the use of organic chlorine solvents, such as trichlorethylene, in affixing *crêpe* soles in the boot trade. The following is a table showing the number of cases of poisoning due to lead, phosphorus, arsenic and mercury, toxic jaundice, epitheliomatous and chrome ulceration and anthrax:—

Disease and industries	1923	1922	1921
Lead poisoning	337 (25)	247 (26)	230 (23)
1. Smelting of metals ..	19 (2)	9 (2)	25 (4)
2. Plumbing and soldering	8 (1)	8	7
2a Shipbreaking	38	17	7
3. Printing	6 (1)	11	12 (1)
4 File cutting	—	—	—
5. Tinning	2	2	1
6 Other contact with molten lead	12 (1)	15	7 (1)
7. White and red lead ..	37	22 (2)	17 (1)
8. Pottery	44 (11)	42 (17)	35 (11)
9. Vitreous enamelling ..	5	3	8
10. Electric accumulators .	95 (2)	32	35
11. Paints and colours ..	11 (1)	14 (1)	13 (1)
12. Indiarubber . ..	5	3	4 (1)
13. Coachbuilding	13 (3)	15 (1)	20 (1)
14. Shipbuilding	8 (1)	12 (1)	4 (1)
15. Paints used in other industries	21	23 (2)	12
16. Other industries ..	13 (2)	19	23 (1)
Phosphorus poisoning ..	—		—
Arsenic poisoning	—	—	1
Mercurial poisoning	4	6 (1)	—
Toxic jaundice	7 (2)	3	1 (1)
Epitheliomatous ulceration ..	58 (4)	32 (3)	32 (2)
Chrome ulceration	58	42	29
Anthrax—	46 (5)	45 (5)	25 (6)
1. Wool	14 (1)	19 (3)	11 (3)
2. Horsehair	9 (2)	9 (1)	4 (1)
3. Handling of hides and skins	22 (1)	16 (1)	8 (1)
4. Other industries ..	1 (1)	1	2 (1)

N.B.—The principal numbers relate to cases, figures in brackets to deaths. Fatal cases not reported in previous years are included as both cases and deaths.

Two cases (one of them fatal) from arseniuretted hydrogen occurred in a dross refining foundry, as a result of a thunderstorm. An alloy of arsenic is present in the dross, capable of giving off comparatively large quantities of arseniuretted hydrogen under the action of cold water. It is known that a compound of aluminium with arsenic readily evolves arsine on treatment with water.

Anthrax.—The figures for wool show the effect of the station for disinfection at Liverpool, only one case having been reported from Bradford. Of the 14 cases, East Indian Wool was present in the wool handled in at least nine. Anxiety exists in the trade as to the risk of anthrax from horsehair, especially that from Russia and Siberia, as out of 18 cases since January 1, 1922, 11 (three fatal) were due to this material. As the plant of the Wool Disinfecting Station at Liverpool cannot deal with tail hair, the question was raised whether the method of steam disinfection of foreign horsehair and bristles required under the German regulations since 1899 could not be adopted.

Four cases of chrome ulceration occurred in a paper mill to persons employed in producing chromate of lead, by double decomposition, the solution of chromate being poured into the beaters containing the half-stuff from whence it passed to the paper machine, producing a yellow-tinted paper. The workers had to feel with their fingers the condition of the "half-stuff" to ascertain when it was fit to be discharged to the mill, and the wearing of gloves for this was impracticable. Since the outbreak, the firm has supplied good washing accom-

modation and first-aid requisites, and has arranged for regular inspection of the fingers. No further cases have been reported.

Inquiry has been made into outbreaks of dermatitis arising from many substances used in industry. The cases may be classified as follows:—Dyes and intermediates 24; alkalis, caustics, acids, 15; turpentine, 14; volatile liquids, spirit polishes, etc., 11; flour, sugar, etc., 9; wood dusts, 6; lime and calcium compounds, 3; miscellaneous, 13; non-industrial, 5. In an inquiry into the prevalence of dermatitis among fur dyers using para- or meta-phenylenediamene, the number of cases found was small, considering the irritative effect of this dye on the skin.

Three non-fatal cases (two of them rescuers) of unconsciousness produced by trichlorethylene occurred in the painting of a brewing vat with a preparation of enamel. No instructions had been given on the label on the container of the enamel, except that when it was used in vats there should be free ventilation. A special cautionary notice is now issued with the enamel.

No definite poisoning from amyl acetate has been observed, although its use has considerably increased. Unless localised exhaust ventilation or good general ventilation is maintained, the workers suffer from headache, drowsiness and throat irritation, particularly when first commencing work. No permanent injury to health results from inhalation of this fume.

The use of solvent recovery plants in the india-rubber industry appears to be increasing owing to the greater efficiency of modern methods of recovery. In some cases 70 per cent. of the solvent spirit is said to be recovered. In the processes of spreading, calendering, and "frictioning," in which a rubber dough, heavily charged with naphtha or similar spirit, is used, there is always a danger that the electrostatic charges created on the surface of the fabric may give rise to sparks and ignite the vapour from the spirit, thus causing a fire or an explosion. This danger is well recognised in the indiarubber trade, and has doubtless hindered the introduction and development of solvent-recovery plants. The use of flue gas has proved successful in preventing fire in solvent-recovery plant.

The possibility of an explosion occurring through the ignition of a cloud of fine dust of any combustible material does not appear to be sufficiently realised by many occupiers and managers of factories. In some cases where the risk is known, the precautions taken to avoid or to minimise it are very inadequate. The majority of explosions due to this cause were due to dusts of carbonaceous materials, *e.g.*, vegetable products, coal, dye substances, naphthalene, ebonite, pitch; but some explosions have been due to sulphur dust, and in previous years explosions from aluminium and magnesium powders have been reported. The manufacture and use of these metallic powders have decreased since the war and additional precautions have been taken by the firms concerned so as to reduce the risk of explosion; no explosion of metallic powders has occurred during the past two years,

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech. ..	£23 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	.. £45 per ton.
Powder ..	.. £47 per ton.
Acid Hydrochloric	.. 3s. 9d.–6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	.. £21 10s.—£27 per ton makers' works according to district and quality.
Acid Sulphuric ..	.. Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali..	.. £6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder	.. Spot £11 d/d.: Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	.. £7 per ton, packages extra.
Borax, Commercial—	
Crystal	.. £25 per ton.
Powder ..	.. £26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	.. £5 17s. 6d. per ton d/d.
Methylated Spirit 64 o.p.—	
Industrial ..	.. 3s. 1d.—3s. 5d. per gallon, according to quantity.
Mineralised ..	.. 4s. 2d.–4s. 6d.
Potash Caustic ..	.. £30–£33 per ton.
Potass. Bichromate	.. 5¾d. per lb.
Potass. Chlorate..	.. 3d.—4d. per lb.
Salammoniac ..	.. £32 per ton d/d.
Salt Cake.. ..	.. £3 10s. per ton d/d.
Soda Caustic, solid	.. Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals ..	.. £5 5s.–£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	.. £24 per ton.
Sod. Bicarbonate	.. £10 10s. per ton, carr. paid.
Sod. Bichromate..	.. 4½d. per lb.
Sod. Bisulphite Powder 60/62%.. ..	.. £18–£19 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate ..	.. 3d. per lb.
Sod. Nitrate refd. 96%	.. £13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £14 10s. per ton d/d.
Sod. Sulphide cryst.	.. £9 per ton d/d.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	.. 5¾d.—1s. 4d. per lb., according to quality.
Crimson ..	.. 1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	**1s. 1d. per lb.**

Barytes	£3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide	3s. 9d. per lb.
Carbon Bisulphide	£24—£26 per ton according to quantity.
Carbon Black	7d. per lb. ex wharf. Dearer.
Carbon Tetrachloride	£56 per ton, drums free.
Chromium Oxide, green	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	45s per cwt., barrels free.
Lead Hyposulphite	7½d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£15 10s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Sulphur Chloride	3d. per lb., carboys extra.
Thiocarbanilide	2s. 6d. per lb.
Vermilion, pale or deep	4s. 10d. per lb
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£14 10s. per ton d/d. Demand active.
Grey	£19—£20 per ton. Fair demand.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 per ton, according to grade and locality. Demand below normal.
Iron Liquor	1s. 7d. per gall. 32° Tw.
	1s. 2d. „ „ 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s 7d. per gall. Unrefined.
Wood Naphtha—	
Miscible	5s. per gall. 60% O.P. Market dull.
Solvent	5s. 6d. per gall. 40% O.P. Fairly good demand.
Wood Tar	£5 per ton.
Brown Sugar of Lead	£46 per ton.

TAR PRODUCTS

Prices in this section show some irregularity according to district. In the North East counties, for instance, anthracene, oil, solvent naphtha and naphthalenes are cheaper than in Lancashire or London. On the other hand, crude carbolic and creosote are dearer.

Acid Carbolic—	
Crystals	6½d.—6¾d. per lb. Fair inquiry.
Crude 60's	1s. 9d.—2s. per gall., according to district. Still quiet but slightly firmer.
Acid Cresylic, 97/99	2s 1d.—2s. 2d. per gall. Demand still good. Market firm.
Pale 95%	1s. 10d.—1s. 11d. per gall. Steady demand.
Dark	1s. 10d.—1s. 11d. per gall. Steady business.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	8½d.—9½d. per gall. Quiet.
Unstrained	7½d.—8½d. per gall.
Benzole—	
Crude 65's	10½d.—1s. per gall. ex works in tank wagons.
Standard Motor	1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure	1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.
Toluole—90%	1s. 5½d. per gall.
Pure	1s. 8d.—2s. per gall.
Xylol coml.	2s. 3d. per gall.
Pure	3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	9d.—9½d. per gall. Few inquiries.
Middle Oil / Heavy Oil / Standard Specification	5½d.—6d. per gall in Lancashire; 7d.—8d. per gall. in Yorkshire.
Naphtha—	
Solvent 90/160	1s. 1d.—1s. 4d. per gall. according to district. Rather better inquiry.
Solvent 90/190	1s. 1d.—1s. 4d. Fair business passing.
Naphthalene Crude—	
Drained Creosote Salts	£4—£6 10s. Quiet.
Whizzed or hot pressed	£9 per ton. Little business.
Naphthalene—	
Crystals and Flaked	£13—£17 per ton in Yorkshire and London respectively. Market quiet.
Pitch, medium soft	52s. 6d.—60s. per ton f.a.s. for next season. Frequent inquiries.
Pyridine—90/160	19s.—20s. per gall. Market less firm.
Heavy	12s.—12s. 6d. Little business.

INTERMEDIATES AND DYES

There has been a fair demand for dyestuffs during the past week. Prices remain constant. A number of intermediate products have been reduced in price.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 7d. per lb.
Acid H	4s. per lb 100% basis d/d.
Acid Naphthionic	2s. 4d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 1d. per lb. Improved demand.
Acid Sulphanilic	9¼d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	7¾d.—8¼d. per lb. naked at works.
Aniline Salts	7¾d.—9d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 1d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 19/31° C.	4½d. per lb. Demand steady.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline	2s. 3d.—2s. 11d. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£85 per ton.
Diethylaniline	4s 7d. per lb. d/d, packages extra, returnable.
Dimethylaniline	2s. 4d. per lb. d/d. Drums extra.
Dinitrobenzene	9d. per lb. naked at works.
Dinitrochlorbenzol	£84 10s. per ton d/d.
Dinitrotoluene—48/50° C.	8d.—9d. per lb. naked at works.
66/68° C.	1s. 2d. per lb. naked at works.
Diphenylamine	3s. per lb. d/d
Monochlorbenzol	£63 per ton.
β Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 4½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 3½d. per lb. d/d.
Nitrobenzene	5¼d.—5½d. per lb. naked at works

o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	11d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis
m-Phenylene Diamine	4s. per lb. d/d.
p-Phenylene Diamine	10s. 3d. per lb. 100% basis d/d.
R. Salt	2s. 6d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 3d. per lb. 100% basis d/d.
o-Toluidine	8½d. per lb.
p-Toluidine	3s. 6d. per lb. naked at works.
m-Toluylene Diamine	4s. 3d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P	£45 per ton.
Acid, Acetyl Salicylic	3s. 3d. per lb. Very heavy demand. Price firm.
Acid, Benzoic B.P.	3s. 6d. per lb. Larger supplies available.
Acid, Boric B.P.	Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	19s.—21s. per lb.
Acid, Citric	1s. 6½d. per lb., less 5% for ton lots. Market extremely firm. Upward tendency.
Acid, Gallic	3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst.	7s. per lb. for 1 cwt. lots. Market firm; increasing demand.
Acid, Salicylic	1s. 6d.—1s. 8d. per lb. Low prices have stimulated more inquiry.
Acid, Tannic B.P.	3s. per lb. Market quiet.
Acid, Tartaric	1s. 1½d.—1s. 2d. per lb. less 5%.
Amidol	9s. per lb. d/d.
Acetanilide	2s. 3d. per lb. for quantity. Demand slow. Prices shaded to secure large orders.
Amidopyrin	13s. 3d. per lb. Neglected. Stocks low.
Ammon. Benzoate	3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	12s. 6d. per oz. for English make.
Barbitone	15s. per lb. Quiet market.
Benzonaphthol	5s. 3d. per lb. Small inquiry.
Bismuth Salts	A steady market. Prices according to quantity:
Bismuth Carbonate	12s. 9d.—14s. 9d. per lb.
„ Citrate	11s. 4d.—13s. 4d. „
„ Salicylate	10s. 2d.—12s. 2d. „
„ Subnitrate	10s. 9d.—12s. 9d. „
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides	Prices vary. Local stocks are being cleared and forward prices are higher. There are rumours of a coming shortage and higher prices in Germany. Average spot values:—
	Ammonium 1s. per lb.
	Potassium 10d. per lb.
	Sodium 11d. per lb.
Calcium Lactate	Demand active. Good English make can be had from 1s. 7d. to 2s. 6d. per lb.
Chloral Hydrate	4s per lb. Very firm and scarce.
Chloroform	2s. per lb. for cwt. lots. Very steady.
Creosote Carbonate	6s. 6d. per lb. Little demand.
Formaldehyde	£55 per ton, *ex* works. English make in casks. About 8s. per cwt. extra for carboys.
Glycerophosphates—	Fair business passing
Calcium, soluble and citrate free	7s. per lb.
Iron	8s. 9d. per lb.
Magnesium	9s. per lb.
Potassium, 50%	3s. 6d. per lb.
Sodium, 50%	2s. 6d. „
Guaiacol Carbonate	10s. 6d.—11s. 3d. per lb.
Hexamine	3s. 6d. per lb. for English make. Market steady.
Homatropine Hydrobromide	30s. per oz.
Hydrastine hydrochlor	English make offered at 120s. per oz.
Hypophosphites—	
Calcium	3s. 6d. per lb., for 28-lb. lots.
Potassium	4s. 1d. per lb.
Sodium	4s. „
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 5d. per lb., according to quantity.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£75 per ton, less 2½%.
Heavy Commercial	£26 per ton, less 2½%.
Heavy Pure	2s.—2s. 2d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	52s. 6d. per lb. Weaker.
Synthetic	26s.—31s. per lb., according to quantity. English make. Strong demand.
Mercurials	Market firm and more active.
Red oxide	5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	3s. 6d.—3s. 7d. „
White precip.	4s. 7d.—4s. 8d. „
Calomel	3s. 11d.—4s. „
Methyl Salicylate	2s.—2s. 3d. per lb.
Methyl Sulphonal	26s. per lb.
Metol	11s. per lb. British make.
Paraformaldehyde	3s. per lb. Ample supplies.
Paraldehyde	1s. 6d. per lb. in free bottles and cases.
Phenacetin	6s.—6s. 3d per lb. Price and demand steady.
Phenazone	7s. 3d.—7s. 6d. per lb. A shade firmer. Forward prices higher.
Phenolphthalein	6s. 6d. per lb. Dealers appear anxious to sell.
Potass. Bitartrate— 99/100% (Cream of Tartar)	88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate	1s. 10d—2s. 2d. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues heavy.
Potass. Metabisulphite	7½d. per lb., 1-cwt. kegs included.
Potass. Permanganate	7d.—7½d. per lb. Keen competition keeps price low
Quinine Sulphate	2s. 3d. per oz., in 100 oz. tins. Very heavy demand.
Resorcin	5s. 6d.—5s. 9d. per lb. Firmer Scarce.
Saccharin	63s. per lb., in 50-lb. lots.
Salol	3s. 6d.—3s. 11d. per lb.
Silver proteinate	9s. 6d. per lb.
Sod. Benzoate, B.P.	2s. 6d. per lb. Ample supplies B.P. quality available.
Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity. Firm in common with other citrates.

Sod. Hyposulphite—Photographic ..	.. £13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside ..	16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt) ..	.. 75s.—82s. 6d. per cwt., according to quantity. Steady market, good demand.
Sod. Salicylate ..	.. Market more active. Powder 2s. 2d.—2s. 4d. per lb. Crystal at 2s. 4d.—2s. 6d. per lb. Flake 2s. 9d. per lb.
Sod. Sulphide—Pure recryst. ..	.. 10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Thymol	.. 18s. per lb. Very scarce indeed. Still rising. Forward quotations 22s. per lb.

PERFUMERY CHEMICALS

Acetophenone ..	.. 12s. 6d. per lb.	
Aubepine ..	.. 15s. 3d.	.. Advanced.
Amyl Acetate ..	.. 2s. 9d.	,,
Amyl Butyrate ..	.. 6s. 9d.	,,
Amyl Salicylate ..	.. 3s. 3d.	,,
Anethol (M.P. 21/22° C.)	4s. 6d.	,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 10½d.	,,
Benzyl Alcohol free from Chlorine ..	.. 2s. 10½d.	,,
Benzaldehyde free from Chlorine ..	.. 3s. 6d.	,,
Benzyl Benzoate	.. 3s. 6d.	,,
Cinnamic Aldehyde Natural ..	.. 15s. 6d.	,,
Coumarin ..	.. 20s.	,,
Citronellol ..	.. 16s.	.. Advanced.
Citral	.. 10s.	,,
Ethyl Cinnamate	13s. 6d.	.. Cheaper.
Ethyl Phthalate ..	.. 3s. 3d.	,,
Eugenol	.. 11s.	.. Advanced
Geraniol (Palmarosa)	.. 35s.	,,
Geraniol	.. 11s.—18s. 6d. per lb.	
Heliotropine ..	. 7s. 9d.	,. Advanced.
Iso Eugenol ..	.. 15s. 9d.	,,
Linalol ex Bois de Rose ..	26s.	,,
Linalyl Acetate ..	.. 26s.	,,
Methyl Anthranilate	.. 9s. 6d.	,,
Methyl Benzoate	.. 6s.	,,
Musk Ambrette ..	.. 45s.	..
Musk Xylol ..	.. 15s.	.. Cheaper.
Nerolin	.. 4s. 9d.	,,
Phenyl Ethyl Acetate	.. 15s.	., Advanced.
Phenyl Ethyl Alcohol	.. 16s.	,,
Rhodinol	.. 57s. 6d.	,,
Safrol	.. 1s. 10d.	,,
Terpineol	.. 2s. 4d.	,,
Vanillin	.. 25s. 6d. per lb.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	.. 15s. 6d. per lb.	
Anise Oil	.. 2s. 8d. per lb.	
Bergamot Oil ..	.. 19s. 6d. per lb.	
Bourbon Geranium Oil ..	36s. 6d. ,,	
Camphor Oil ..	.. 75s. per cwt.	
Cananga Oil Java	.. 10s. 6d. per lb.	
Cinnamon Oil, Leaf	.. 6½d. per oz.	
Cassia Oil, 80/85%	.. 8s. 9d. per lb.	
Citronella Oil—Java 85/90% ..	. 5s. 9d. per lb.	Cheaper.
Ceylon .. .	. 3s. 7½d. per lb.	Cheaper
Clove Oil	.. 7s. per lb.	
Eucalyptus Oil 70/75% ..	2s. per lb.	
Lavender Oil—French 38/40% Esters	29s. per lb.	
Lemon Oil ..	.. 3s. per lb.	
Lemongrass Oil	.. 3d. per oz.	
Orange Oil, Sweet	.. 13s. 3d. per lb.	
Otto of Rose Oil—Bulgarian ..	.. 30s. per oz.	
Anatolian .	. 26s. per oz.	
Palma Rosa Oil ..	.. 19s. per lb.	
Peppermint Oil—Wayne County	.. 20s. 9d. per lb.	
Japanese ..	.. 14s. 3d. per lb.	
Petitgrain Oil	.. 9s. 6d. per lb.	
Sandal Wood Oil—Mysore	.. 26s. 6d. per lb.	
Australian ..	.. 21s. per lb.	

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before Sept. 1, 1924; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on July 31.

I.—Applications

Deckers. Preventing formation of and removing boiler scale. 16,430. July 9.

Felten und Guilleaume Carlswerk Akt.-Ges. Acid proof coating for metallic vessels. 16,510. July 9. (Ger., 12.2.24.)

Gill and John. Drying apparatus. 16,529. July 9.

Kempter. Crushing and kneading mills. 16,333. July 8.

Kuntz. Rotary driers. 16,308. July 7.

Metropolitan-Vickers Electrical Co., Ltd. Means for obtaining inert atmospheres. 16,596. July 10. (U.S., 20.7.23.)

Naamlooze Vennootschap Utrechtsche Fabriek van Centrale Verwarming and Constructiewerken voorheen H. Zimmermann & Co., and Zimmermann. Drying. 16,631. July 10.

I.—Complete Specifications Accepted

3197 (1923). Woodall, Duckham, and Jones (1920), Ltd., and Duckham. Annular furnaces or kilns. (218,343.)

6251 (1923). South Metropolitan Gas Co., Woodall, Duckham, and Jones (1920), Ltd., and Hatfield. Electrostatic separation of particles. (218,354.)

13,762 (1923). Keene. Filtering-apparatus. (218,117.)

15,141, 26,042, 26,043, and 27,226 (1923). Fink. Separating liquids. (218,462.)

16,010 (1923). Aktiebolaget Separator. Centrifugal separators. (202,616.)

21,303 (1923). Appareils et Evaporateurs Kestner. Crystallisation processes. (214,572.)

29,784 (1923). Appareils et Evaporateurs Kestner. Vertical evaporators. (218,556.)

30,589 (1923). Greaves. Apparatus for washing granular material. (218,561.)

II.—Applications

Duffield. Apparatus for producing gas from powdered carbonaceous matter. 16,598. July 10.

Heyl. Distillation and utilisation of oil shale etc. 16,285. July 7.

Klotzer. Method of recovering combustible gases from fuel. 16,480. July 9.

Marks (Kohlenscheidungs Ges.). Rotary drums for distillation of coal etc. 16,708. July 11.

Marks (Kohlenscheidungs Ges.). Production of fuel from semi-coke. 16,709. July 11.

Niece. Apparatus for treating hydrocarbons 16,726. July 11.

Techno-Chemical Laboratories, Ltd., and Testrup. Treatment of peat. 16,793. July 12.

II.—Complete Specifications Accepted

359 (1923). Jackson (Koppers Co.). Coking retort ovens. (218,339.)

9491 (1923). Martel. Agglomeration of fuel (218,391.)

11,786 (1923). British Thomson-Houston Co. (General Electric Co.). Filaments for electric incandescent lamps. (218,430.)

19,824 (1923). Humphreys and Glasgow, Ltd. (Rasby). Carbonisation of bituminous coal and like material. (218,512.)

5770 (1924). Simon. Combustion of readily combustible waste and residues (218,598)

III.—Application

Pease and Partners, Ltd., and Robinson. Recovery of pyridine etc. from by-products. 16,283. July 7.

III.—Complete Specification Accepted

29,314 (1923). Weil, and Chemische Fabrick in Billwarder vorm. Hell u. Sthamer Akt.-Ges. Obtaining pure anthracene and carbazole from crude anthracene. (210,742.)

IV.—Applications

Farbwerke vorm. Meister, Lucius, und Bruning. Manufacture of dyestuffs 16,407. July 8. (Ger., 23.7.23.)

Morton Sundour Fabrics, Ltd., Wylam, and Jones Dyes and dyeing. 16,805. July 12.

Soc. of Chemical Industry in Basle. 16,406 *See* XX.

IV.—Complete Specifications Accepted

15,644 (1923). Pereira. *See* XX

27,233 (1923). Ransford (Cassella und Co. Ges.). Production of acridinium compounds. (218,542.)

31,359 (1923) Bloxam (Chem. Fabr. Griesheim-Elektron). Manufacture of azo dyestuffs. (218,568.)

V.—Applications

Akt.-Ges. fur Anilin-Fabrikation. Manufacture of viscose silk. 16,512. July 9. (Ger., 8.8.23.)

Akt.-Ges. fur Anilin-Fabrikation. Manufacture of viscose silk. 16,741 July 11. (Ger, 20.8.23.)

Akt.-Ges. fur Anilin-Fabrikation. Manufacture of viscose products. 16,742. July 11. (Ger., 22.8.23.)

Granton. Utilisation of waste material from de-inking of paper. 16,626. July 10.

V.—Complete Specifications Accepted

9284 (1923). Colas, Colas, and L'Alfa, Soc. Anon. Treating liquor from the lixiviation of vegetable matter. (218,385.)

10,477 (1923) Walker. Nitration of cellulose (218,411.)

VI.—Applications

Bailey and Gee. Machines for treating fabrics with liquids. 16,542. July 10.

Germann. Dyeing and simultaneously water-proofing etc material. 16,555. July 10.

Johnson (Smith, Drum and Co.). Dyeing etc. machines. 16,371, 16,372, and 16,373. July 8.

Morton Sundour Fabrics, Ltd. 16,805. *See* IV.

VII.—Applications

Legeler. Production of carbon disulphide. 16,704. July 11.

Spence, and Spence and Sons, Ltd. Production of ferric sulphate 16,342. July 8.

VII.—Complete Specifications Accepted

3292 (1923). Worsley. Production and use of hyposulphurous acid. (218,347.)

9075 (1923). Ewan. Manufacture of sodium. (218,373.)

27,977 (1923). Harr. *See* VIII.

30,872, and 30,873 (1923). Ewan. Manufacture of alkali metals. (218,563.)

32,200 (1923). Dorr Co. Manufacture of whiting. (212,877.)

9621 and 9622 (1924) Ewan Manufacture of sodium or potassium. (218,606.)

VIII.—Applications

Donald. Manufacture of bricks and pottery. 16,568. July 10.

Refractories Process Corporation. Processes for manufacturing high refractories. 16,497. July 9. (U.S., 14.8.23.)

Wade (Dixon Co.). Plate-glass annealing-leers. 16,325. July 7.

VIII.—Complete Specifications Accepted

18,438 (1923). Siemen. Manufacture of fire-proof bricks. (218,495.)

27,977 (1923). Harr. Manufacture of sintered magnesite and magnesite bricks. (207,172.)

IX.—Application

Collins and Gollop. Cement. 16,111 July 9.

IX.—Complete Specification Accepted

29,773 (1923). Lyon. Artificial seasoning of wood. (208,522.)

X.—Applications

Brookfield. Cupolas etc 16,696. July 11

Cachemaille (Westinghouse Lamp Co.) Extraction of metals from compounds. 16,275, 16,278. July 7

Folkerts. Steel conversion 16,584. July 10.

Hannay. Treatment of stibnite etc. 16,672. July 11.

Minerals Separation, Ltd., and Lavers. Concentration of ores. 16,787. July 12

Naamlooze Vennootschap Philips' Gloeilampenfabrieken. Separation of hafnium and zirconium 16,788. July 12. (Denmark, 13.7 23.)

Refractories Process Corporation. Metallurgical furnace roof. 16,498. July 9. (U S, 14.8.23)

X.—Complete Specification Accepted

2878 (1924). Fox. Treating the surface of bronze, brass, and like metals. (218,591.)

XI.—Applications

Cachemaille (Westinghouse Lamp Co) Manufacture of electron-emitting material etc 16,273 July 7

Cachemaille (Westinghouse Lamp Co). Cathodes for vacuum electric devices. 16,274. July 7.

Cachemaille (Westinghouse Lamp Co.). Activated material for electron emission. 16,276. July 7

Nordiske Fabriker De-No-Fa Aktieselskap. Electrolytic decomposition apparatus. 16,521. July 9. (Norway, 29 8.23.)

XI.—Complete Specifications Accepted

6251 (1923) South Metropolitan Gas Co., Woodall, Duckham and Jones (1920), Ltd, and Hatfield. *See* I.

29,097 (1923). Correra Electrolytic tanks (207,199)

32,215 (1923). Elektro Osmose Akt. Ges. (Graf. Schwerin Ges.). *See* XII.

388 (1924). Elektro-Osmose Akt.-Ges. (Graf. Schwerin Ges.). *See* XV.

XII.—Applications

Plauson, and Plauson's (Parent Co), Ltd. Production etc. of sulphur soaps. 16,647. July 11.

Schneler. Presses for expressing oil from seeds etc. 16,643. July 11.

XII.—Complete Specifications Accepted

15 394 (1923). MacIlwaine. Preservation and preparation of copra. (218,465.)

32,215 (1923). Elektro-Osmose Akt.-Ges. (Graf. Schwerin Ges.) Electro-osmotic purification of glycerin. (214,576.)

XIV.—Application

Plauson, and Plauson's (Parent Co.). Materials for use in rubber mixings etc. 16,422. July 9.

XIV.—Complete Specifications Accepted

8745 (1923). Feldenheimer and Plowman. Manufacture of rubber compositions. (218,364.)

9269 (1923). Naugatuck Chemical Co. *See* XX.

27,759 (1923) General Rubber Co. Concentrating latex etc. (218,544.)

XV.—Complete Specification Accepted

388 (1924). Elektro-Osmose Akt.-Ges. (Graf. Schwerin Ges.). Process for the electro-osmotic purification of glue or gelatin. (214,579.)

XVII.—Application

Urban. Purification of sugar solutions. 16,525. July 9.

XIX.—Application

Brashier. Manufacture of volatile solid insecticides etc. 16,630. July 10.

XIX.—Complete Specification Accepted

9808 (1923). O'Shaughnessy. Treatment of sewage liquor etc. (218,399.)

XX.—Applications

Akt.-Ges. fur Anilin-Fabrikation. Manufacture of vanillin. 16,634. July 10. (Ger., 28.7.23.)

Burdick. Process of making olefin oxides. 16,507. July 9.

Pease and Partners, Ltd., and Robinson. 16,283. *See* III.

Soc. of Chemical Industry in Basle. Manufacture of acylated diamines. 16,406. July 8. (Switz., 17.7.23.)

XX.—Complete Specifications Accepted

9369 (1923) Naugatuck Chemical Co. Processes for the manufacture of diphenylguanidine. (199,354.)

14,486 (1923). Green, Oxley, and British Dyestuffs Corporation, Ltd. Separating alkylamines from ammonia and other gases (218,458.)

15,644 (1923). Perera. Process of manufacturing amino-perylene-quinones. (199,721.)

28,190 (1923). Austerweil and Peufaillit. Process for the production of *p*.-cymene from monocyclic terpenes. (206,848.)

XXI.—Application

Kovasznay and Tolnay. Photographic plates. 16,309. July 7.

XXIII.—Complete Specification Accepted

7380 (1924). Optische Anstalt C. P. Goerz Akt.-Ges. Refractometers. (213,286.)

GENERAL NOTES

Official Trade Intelligence

The Department of the Overseas Trade Development and Intelligence, 35, Old Queen Street, London, S.W. 1), has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting specific reference number: *Australia:* Brass tubes (82); Hardware, aluminium, enamelled ware, (83); *Austria:* Leather (B.X./1079); *British East Africa:* Water piping (84); *British India:* Steel (The Director General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E. 1); *Canada:* Steel, iron, hardware (87); Leather, china and hollowware (89); *Germany:* Shellac, copra (94); *Malta:* Soap (90); *New Zealand:* Hardware (91); *Norway:* Leather goods (95); *Siam:* Steel (A.X./1149); *South Africa:* Brassware, paint, oil, builders' hardware (92); Steel, iron (C.X./1067); Brass piping, copper sheet, (A.X./1151); *Spain:* Hardware (97); *United States:* Scientific instruments (101); Steel (A.X./1144); Steel tubing and piping (C.X./1070); *Uruguay:* White varnished porcelain insulators (B.X./1093).

Chemical Industry in Czechoslovakia

According to the report of the Association of Czechoslovak Chemical Industries, the position of the large chemical works in Czechoslovakia during 1923 was more favourable than in 1922. Imports of raw materials, and the output and export of heavy chemicals increased to a large extent. The larger demand for phosphatic acid and nitrogenous fertilisers increased unemployment, and although chemical factories in general were really not much busier than in 1922, confidence in the future has been restored, and a steady development of the industry may be expected. Conditions in the petroleum industry continued unfavourable, and the dyeing industry generally did not derive the same benefit as other branches of the chemical industry from the temporary slump in German production. The pharmaceutical industry, however, did well in the home market, whilst the starch industry also had a good year, the export trade developing. A smaller consumption characterised the varnish industry, and there was a reduced output of mineral oil. Other branches of industry included lubricating oils, coal-tar, boot polishes, candles and soap. The perfumery industry recovered from its heavy losses to some extent, and employment in the rubber industry was decidedly better in 1923 than in the previous year, whilst a better market was also found for grinding and polishing materials later in the year.

Polish Output of Potash

The total production of potassium salts in Poland during 1923 amounted to 61,503 metric t. as compared with 46,082 t. in 1922, an increase of 38 per cent. over that of 1922 and a much larger gain over previous years. There was a slight decrease in the production of sylvinite during 1923, but the production of kainite considerably exceeded that of 1922, the figures being: Sylvinite, 39,375 t. (43,562 t. in 1922) and Kainite, 22,128 t. (2520 t. in 1922). Deposits at Drohobycz and Stanislawow were worked in 1923, the latter employing 405 out of a total of 559 workmen engaged in the industry.

EDITORIAL

DURING this week the first Empire Mining and Metallurgical Congress is being held at the British Empire Exhibition. The main object of the Congress—to take stock of Empire mineral resources and to discuss measures for their development and utilisation—is one that will appeal to all our readers. The time between the opening of the Congress and our going to press is too short, even were sufficient space available, to give an account of it, but we are told that the successful opening meeting was attended by a representative gathering, including delegates from the United States present as guests. On Wednesday the Congress listened to the "May Lecture" of the Institute of Metals delivered by Dr F. W. Aston—a summary of the lecture will be found on another page of this issue—and papers are to be read by nearly all the well-known workers connected with metalliferous and coal mining, safety problems in mining, the transport, production and refining of petroleum, and ferrous and non-ferrous metallurgy. Nature, as Lord Long pointed out in his opening address, has been prodigal in her gifts of minerals to the various lands which constitute the British Empire. But let the visitor to the Exhibition obtain the excellent handbook, "Minerals of the Empire" at the stand of the Imperial Mineral Resources Bureau, and he will see how the output from the Empire compares with that of the rest of the world. Asbestos, china clay, chrome ore, diamonds, gold, mica, nickel, the output of all these represents over half the world's production, but the figures for bauxite, copper, graphite, iron ore, and petroleum show a proportion of under one-tenth, although the proportions for important products such as manganese, coal, tin, lead and zinc are much higher. This is not a reason for despondency, however, as production does not imply a measure of the reserves, and estimates of reserves are always conservative. Each time a survey of England's reserves of coal has been made the estimated reserves have grown, and so it will probably be with other minerals, particularly as so small an area of our vast Empire has yet been surveyed minutely. By the time this journal is published, the Congress will be practically over, and one hopes for very beneficial results. Valuable as the effect will undoubtedly be, development will ultimately depend on the attitude of the financier and the facilities for transport, but that is hardly within the scope of a scientific congress.

* * *

The review which we publish this week by G. T. M. of "Chemistry in the XXth Century" directs attention to a remarkable achievement. The review mentions in detail the contents of the book and praises with faint damns—if that is the correct quotation—the scientific treatment of the subjects. The really notable fact about the matter is that a large, handsome and well-printed book can be made of the present state of certain chapters of chemistry with special reference to the work of British chemists, and that so much is left over for future publications. We can hardly recollect any chemical book we have read which presents so many topics to excite our curiosity and compel us to learn more. The cause of this is obvious: there is a story in each chapter, a design, a plot. There is hardly a page in the book which does not reveal a search for some explanation of fundamental importance; we are continually left stranded on the border which lies between the well-surveyed land and the mysterious ocean of ignorance. This provides a sense of fascination, and we see more clearly what perhaps many of our readers never forget, the underlying purpose stimulating the collection and dissemination of myriads of details. Mr. Samuel Weller said that the great art of letter-writing was to end so that the reader wanted more. The President of the Society of Chemical Industry will long feel a just pride in this book.

THE MANUFACTURE AND USES OF GLYCERINE

Glycerine was discovered by Scheele in 1779, and although Chevreul showed, some forty years later, that it was an invariable constituent of fats and oils, and was produced when they were saponified, it was not until the 'fifties of the nineteenth century that commercial quantities were demanded. About that time Prices Candle Co. was selling a good commercial glycerine, but it was not until the late 'seventies, when the usefulness of nitroglycerine—discovered in 1863 by Nobel began to be appreciated, that really large amounts of glycerine were in demand From that date the application of glycerine in many industries has steadily increased

Glycerine is one of the few really pure industrial products, ranking with sugar and liquid ammonia. The so-called "C P" variety contains essentially nothing but glycerine and, say, 1 per cent. of pure water When it is remembered that it often originates in the lyes of the soap maker, which contain in addition salt, sodium sulphate, carbonate, hydroxide, acetate, butyrate, caproate, salts of iron, calcium and arsenic, and various sulphur compounds, and that volatile fatty acids are formed when the salts are acidified, some idea may be gained of the difficulties besetting the refiner. In the distillation, too, volatile fatty acids, ammonia and amines and trimethylene glycol must not be allowed to contaminate the distillate, nor must albuminoid or resinous matters or polymerised glycerine be permitted to be carried out of the still The production of a pure product from such a source reflects the greatest credit upon British chemical plant manufacturers, inventors and technical chemists.

Sources and Manufacture of Crude Glycerine

The principal source of crude glycerine is found in the lyes from soap and candle making Natural and hydrogenated fats and oils, consisting chiefly of mixed glycerides, are saponified by means of caustic alkalis, whereupon a soap is produced and glycerine remains in the lyes separated from the curd formed on the addition of common salt to the soap kettle after boiling. The lyes also contain the impurities noted above Treatment with lime, aluminium or ferric salts forms a precipitate of the corresponding metallic soaps and the higher fatty acids which entangles much of the resinous and albuminoid matter present in the lyes After filtration and neutralisation, the treated lyes are concentrated This operation is usually conducted in special vacuum evaporators, and concentration is taken past the salt point without breaking the continuity of operations, a high vacuum process and special designs of plant preventing the deposition of salt upon the evaporator surfaces. The salt is washed and returned to the soap-making process. The concentration is carried on until a "soap lye crude" glycerine, containing about 80 per cent. of glycerine, 10 per cent of salts and 10 per cent. of water is obtained. This is a yellowish viscous liquid, without unpleasant taste but still containing organic impurities. Methods of testing for alkali, fatty acid salts, total ash, and organic residue have been standardised by agreement (the Internation[al] Standard Methods "I. S. M." pamphlet, 1911 and all crude glycerines are bought and sold—at an rate in this country upon contracts embodyin[g] penalties and allowances, the whole resting upo[n] the results of analyses carried out by standardise[d] methods. The methods have recently been care fully revised and improved.

Saponification Crude

Perhaps the best type of crude glycerine is tha[t] obtained from the autoclave saponification process of fat splitting, employed, say, in the candle industry a mixture of fats and water being converted under pressure, usually in the presence of catalysts such as lime, zinc and zinc oxide, or magnesia, into fatty acids and glycerine. The lyes or sweet water are fairly pure, and after acidification and, if desired, treatment with aluminium or iron salts, as in the case of soap lyes, they are concentrated until a crude product containing from 85 up to 90 per cent. of glycerine is obtained. Relatively little ash is found in this type of crude glycerine, whilst the organic matter is normally fairly low as compared with soap lye crude.

The glycerine solutions resulting from the splitting of fats, oils and greases by means of the Twitchell reagent are worked up broadly in a similar manner, the acid present being first neutralised and a purification (precipitation) treatment being applied if desired. The crude glycerine obtained is often of lower quality than that from the autoclave process not necessarily because the process is inherently faulty, but because low-grade fats and greases are often used in this splitting process. The ash content and organic residue are relatively high, and the crude glycerine has an unpleasant taste.

Two sources of glycerine which are of relatively smaller importance are found in the so-called fermentation crudes and distillation crudes. Fats and oils may be split by means of the enzyme contained in castor seeds, but the glycerine liquors often contain large quantities of albuminous matter, and are difficult to separate from the fatty acids produced and difficult to refine. Although the fermentation splitting process has been very considerably improved, it is applied only to a limited extent. Effective separation from fatty acids and emulsified organic matter must be attained before concentration to crude glycerine is attempted.

Crude distillation glycerine is so called because the fatty acids resulting from the hydrolysis of fats by means of sulphuric acid must be distilled before employment in the candle industry. On account of the relatively large quantities of sulphuric acid in the sweet water, the crude glycerine obtained upon evaporation contains considerable ash—in the form of calcium sulphate, when lime has been used to neutralise the acid whilst the organic residue is also rather high. Trouble is often experienced in the evaporation of the neutralised sweet water by reason of the separation of calcium sulphate on the heating surfaces.

By careful manipulation in the working up of any form of glycerine solutions (particularly those

rom the first three processes noted) a good crude product containing upwards of 80 per cent. of glycerine can be obtained, and it is often possible to apply a good crude directly, or after decolorising treatment, in industry. By far the most common practice, however, is to distil the crude product in vacuo, superheated steam being used in order to help to carry over the glycerine. By careful distillation, followed in certain cases by redistillation, it is possible to win glycerine of the highest purity, provided that effective purification has been achieved in the production of the crude glycerine. Mineral salts, albuminous and resinous impurities, volatile fatty acids, and ammonia and amines remain in the crude to a greater or less extent, but the salts and high boiling materials are retained in the still together with polyglycerols—present or produced during distillation—whilst the volatile bases and acids passing over with the steam and glycerine vapours are kept out of the glycerine by fractional condensation.

Distillation

Many types of still have been designed since the time of the old fire-heated apparatus, and refinements have resulted not only in the possibility of obtaining regularly a high quality of glycerine, but also in the reduction of the costs of the process. In general terms, the process consists in heating the crude glycerine by means of closed steam coils in a suitable still, fitted with baffling devices to prevent the spraying of even the smallest trace of the still contents over into the condensers where, of course, it would contaminate the condensed glycerine. Superheated steam, preferably generated from distilled water, is blown into the charge in the still, whereupon, under the conditions of high vacuum prevailing, the glycerine is vaporised and carried in the steam current to a series of condensers. The primary cooling is so arranged as to condense glycerine at such a temperature as to allow the steam to pass without condensation, so that the product from the primary condensers is essentially glycerine. Further condensation leads to progressively "weaker" glycerines, until finally the so-called sweet water, containing a recoverable amount of glycerine is condensed. According to the quality of glycerine demanded (*v. infra*) the condensates are directly marketed, concentrated in vacuo to a higher glycerine content, or redistilled. For the highest grades—chemically pure glycerine perfect decolorisation is effected by means of a highly efficient decolorising carbon, and, in addition, special processes for the total removal of arsenic are worked.

A brief description of a more complex distillation system which is continuous in operation, economical in fuel consumption and capable of yielding high-grade products may be given as an illustration of the improved practice which now obtains in British glycerine refineries.

A single current of steam is used to distil the glycerine from a number of stills, the glycerine being injected into the steam current so that the hydrostatic head of quantities of glycerine in a series of several stills is eliminated. The steam is generated in a multiple effect evaporator, containing the sweet water produced in the final condensation, and mixes with the injected glycerine in the tubes of the stills after suitable superheating. Glycerine is vaporised under the 28 in. vacuum prevailing and passes with the steam to a condenser, surrounded by water boiling under reduced pressure at 175° F., and is condensed, giving up its heat to the boiling water and thus furnishing steam which may be utilised in the process. The uncondensed steam passes to the second still, where the operations are repeated until after a series of stills has been worked, the steam is condensed with the small remaining amount of glycerine vapour to form sweet water. The mixture of salts, polyglycerols, etc., which remains in the still of whatsoever type used may be treated for the recovery of any glycerine contained, or it may be directly employed for some industrial purposes.

Types of Glycerine Produced

Two general types of glycerine are ordinarily produced by the distiller, namely, dynamite glycerine and "C. P." glycerine. Slight variations from the specifications fulfilled by these two types are made to suit various consumers, who may desire a pure glycerine but do not require a product containing a maximum 1·5 per cent. of water. In other cases, the so-called industrial white glycerine may satisfy when the slightly coloured dynamite glycerine is unsatisfactory, but where the complete and absolute purity of the "C. P." product is not essential.

Nobel's specification for dynamite glycerine demands a glycerine which is neutral to litmus, of light colour and affording no unpleasant smell when heated to 100° C. It shall contain a minimum of 98·5 per cent. of glycerine when tested by the acetin method (I. S. M. procedure), and possess a specific gravity of 1·262 at 15·5° C. The percentage of chlorides, reckoned as NaCl shall not exceed 0·01 per cent., nor shall the total ash exceed 0·05 per cent. When 10 c.c. each of 10 per cent. solutions of the glycerine under test, ammonia and silver nitrate are mixed, heated to 60° and then kept in the dark for ten minutes, there shall be no apparent reduction of the silver salt, as evidenced by a darkening. This test indicates the absence of formic acid, acrolein, etc., which might cause undesirable rise of temperature in the nitrating operations to which the glycerine is to be subjected, and the test is of great importance. The saponification equivalent of the glycerine shall not exceed 0·1 per cent. calculated to Na_2O.

Chemically pure or C. P. glycerine passes the rigid specification of the British Pharmacopœia, which calls for a clear colourless liquid of no odour, showing no reaction for ammonium, chlorides or sulphates. It must not contain lead, iron and copper, whilst the arsenic limit is set at 4 parts per million. Tests must reveal the absence of fatty acids, and the silver nitrate test must show the absence of formic acid and acrolein.

Properties and Uses of Glycerine

The chemical and physical characteristics of glycerine permit its wide application. Thus, the reactivity of the hydroxyl groups enables various esters of value to be readily produced. In addition, it possesses antiseptic and preservative properties and is an excellent emollient for the skin. It mixes with alcohol and water in all proportions and dissolves many drugs and chemicals to a greater extent than does water. It is odourless, but easily and pleasantly perfumed when desired, whilst its sweet, agreeable taste renders it useful, especially in view of its solvent action, in medicinal preparations. It is a good excipient for various materials. It is very hygroscopic and its solutions in water possess a low freezing point. Its viscous character makes it a good lubricant.

Nitroglycerine.—One of the largest applications of glycerine is in the manufacture of the ester, nitroglycerine, which is an essential component of dynamite, blasting gelatine and cordite. Glycerine is therefore a basic chemical both in peace and war. A perfectly pure, colourless glycerine is not required for nitration, but certain easily oxidised impurities must be absent. The specification given above for dynamite glycerine is more than fulfilled by British manufacturers.

Nitration is effected by means of a mixture of nitric and sulphuric acids, the product being washed free of acid. The extreme care which is necessary in manufacture and the technical details essential to the production of a standard material cannot be indicated in this article, and it must suffice to state that the industry is highly efficient.

Small quantities of nitroglycerine are used in medicine.

Glycerine Acetates—Acetins.—Glycerine is readily converted into its acetic esters, the acetins, by heating with acetic anhydride and potassium bisulphate.

Commercial acetin usually consists of a mixture of the di- and tri-acetins, that is, glycerine in which two or three of the hydroxyl groups have been replaced by the acetyl radical. The monoacetin, obtained with the aid of acetic acid, is also somewhat in demand. The acetins are chiefly employed as an adjunct in calico printing.

Glycerine Arsenite.—Arsenious oxide behaves as an acid when heated with glycerine at about 250° C., for glycerine arsenite is obtained. It decomposes above 250°. This compound is also employed in calico printing.

The Chlorhydrins.—The chlorhydrins are esters of glycerine and hydrochloric acid, whilst epichlorhydrin is formed by the esterification of one hydroxyl group and the removal of one molecule of water from the other two hydroxyl groups of the glycerine molecule. The chlorhydrins and epichlorhydrin possess some importance as solvents, especially for hard resins, such as copal, which often dissolve in the cold.

Glycerophosphoric Acid.—The monophosphoric ester of glycerine is prepared by heating a suitable mixture of the trihydric alcohol and the acid to about 105°, above which temperature the di-ester is formed in addition. It is a colourless, odourless liquid, usually met with in aqueous solution, which is decomposed upon heating. Its salts are far more important and find extensive application in medicine, for instance, as nerve tonics. Calcium glycerophosphate and iron glycerophosphate are often combined with other medicinals, such as nux vomica (strychnine) as well as emulsified with cod liver oil, petroleum, etc.

In the human system, glycerophosphoric acid occurs in the lecithin of brain and nerve tissue.

For the preparation of glycerophosphates pure glycerine must obviously be used, the above esters, used in industry, being made from dynamite glycerine or industrial glycerine.

Medicinal Preparations.—A glance through the British Pharmaceutical Codex reveals the scores of medicinal preparations into which glycerine enters. The reason for its value may be one of many. In some cases it is used merely as a convenient excipient. In others it is a useful solvent, and permits a greater penetration into the cell than does water, for instance. Again, its agreeable taste conceals the bitter or nauseous taste of certain drugs and medicines.

Glycerine, taken internally, is demulcent, antiseptic and somewhat nutritious. It was used to some extent, particularly before the introduction of saccharin, for sweetening the food for diabetic persons. On account of its soothing effect it is employed in many cough medicines and, associated with gelatin, in the preparation of pastilles.

Glycerine of boric acid or a simple solution of boric acid in aqueous glycerine, is a useful throat antiseptic.

The preservative action of glycerine is made use of in preparing compositions containing digestive ferments. Thus, glycerine of pepsin is made by acting upon pepsin with aqueous glycerine in the presence of hydrochloric acid, allowing the mass to stand for a week and filtering. The preparation made up in standard strengths is a valuable digestive.

There are scores of preparations of similar nature to those indicated above, which have been arbitrarily selected as types demonstrating the use of glycerine for some specific property it possesses.

One final instance of its antiseptic and preservative action is of interest. Glycerinated calf lymph is considered the safest medium for vaccination. In this preparation the glycerine destroys all non-spore-bearing extraneous organisms.

Toilet Preparations.—In the realm of toilet preparations, glycerine finds hundreds of applications, its use depending upon its emollient and antiseptic action. In skin preparations it is associated with water, fats or oils, gelatin, agar-agar, Irish moss, starch, to form skin washes, pomades, salves, jellies, creams, and so forth.

Glycerine is a component of tooth pastes and general dentifrices, hair washes and hair dyes, nail polishes, hair oils and shampoo preparations, pomade hongroise, "make-up" and other preparations.

Glycerine has also a healing action upon broken skin, chapped hands, and so forth, being employed, diluted with water, perfume solutions, and oil.

Transparent Toilet Soaps.—Glycerine is, of course, present in "cold process" soaps, but it is also actually added to some varieties of transparent toilet soaps.

Beer and Wine.—The preservative action of glycerine is also made use of in the brewery, the beers, in addition, being stated to be improved of taste. Wines acquire body and flavour with the addition of glycerine, it is claimed, although in these latter instances it is not clear that any extensive application of glycerine is in evidence. Indeed, it may here be noted that many of the "uses of glycerine" set out in literature are suggestions only, or applications which have long since been discarded. The information has been studiously copied however, and the sixty uses presented in a pamphlet in the late seventies appear with monotonous regularity.

Glycerine as a Lubricant.—Glycerine is, of course, much more expensive than ordinary lubricants, but there are instances where it can profitably be employed. In delicate machinery lubricated with glycerine, no sticky or hard frozen products of oxidation or cooling interfere with good working. Apparatus which is to come into contact with foodstuffs may very well be lubricated with glycerine, for obvious reasons. The use of glycerine alone or in aqueous solution has also been suggested for liquid air and refrigerating apparatus. In the former case, its use is scarcely to be recommended.

Anti-Freeze Compositions.—Glycerine and its aqueous solutions possess a low freezing temperature. Plain solutions or special preparations are used in gas meters to a limited extent, and in motor car radiators, quick-firing guns, and hydraulic testing gear. Anti-dimming compositions also contain glycerine.

Tobacco is sometimes treated with glycerine solution, the hygroscopic properties of the glycerine being utilised in keeping the tobacco moist. The use of glycerine here could be considerably increased with advantage, although cheaper substances are available. Glycerine possesses an advantage over all, as it inhibits fermentation and mould growth and acts as a general preservative and as an aid to the development of flavour.

Foodstuffs such as jams, fruits, etc., are preserved better in the presence of glycerine, the use of which for this purpose is increasing, as glycerine has no harmful effect upon the human system.

Inks and Duplicating Compositions contain glycerine. In this field—the production of copying inks, lithographic inks, duplicating compositions, special papers for receiving impressions, printer's roller compositions—there are scores of formulæ, and glycerine is almost an invariable constituent. It is known that the well known manufacturers have their own formulæ which have only been arrived at through long experience and experiment, and which represent the last word in this field. These manufacturers use glycerine in their products.

It is, therefore, unnecessary to burden this article with uninteresting formulæ, as these, in any case, would not represent the best practice, which is kept a profound secret.

General.—Glycerine is used in the textile industry to a certain degree in finishing operations, improving the appearance and feel of the products. In the softening of chamois and other leathers and as a polishing agent in compositions, it is employed in the tannery, whilst it is a good preservative for pelts which are not intended to be subjected to the ordinary processes of preservation.

In preserving anatomical specimens it has advantages over alcohol. Its capacity for attracting and retaining moisture is made use of in keeping modelling clays and plasters in the moist condition. It is useful in removing coffee and other stains from textiles, many colouring matters being soluble in glycerine. Simple rubbing with a glycerine impregnated cloth with subsequent treatment with spirit or soap and water is very efficacious in many instances. It has been found the best material over which to store hydrogen, as foreign gases, such as nitrogen, diffuse at a minimum rate into the pure hydrogen. It is suggested as a component of rust-resisting compositions and for purifying domestic coal gas from sulphurous impurities. The latter application, although successful in the laboratory, has not been developed in any large degree in practice.

It is employed in the preparation of photographic emulsions, although the exact manner of its use is a well-kept secret.

THE TRAINING OF CHEMISTS IN BACTERIOLOGY

By Dr. DAVID ELLIS

Those of us whose duty it is to give instruction to chemists in the science of bacteriology are aware that there is a quickening of interest in the subject which is an agreeable change when we reflect on the general apathy which distinguishes the chemists of even a decade ago. Formerly the visitors who trod the corridors which gave access to the bacteriological laboratories of the Royal Technical College of Glasgow unconsciously trod lightly lest they should awaken the sleepers, which they felt were reposing in the laboratories. Nowadays, whilst it is not exactly necessary yet to compel intending workers to line up in a queue so as to make their entrance in an orderly manner, it is necessary to make provision for a large inflow of students. The budding chemist of to-day feels, and feels rightly, that a study of bacteriology is an essential part of the equipment of the modern chemist who is going to offer his services to one or other of the many branches of industrial concerns. Such being the case, it behoves us to examine the whole matter in the light of the conditions which now hold in the industrial world. Also, it is necessary to ascertain how far the educational equipment of the chemist is adequate to meet the demands that will be made upon him. The latter appears to the writer to be the more important of the two and will be dealt with first. The fact is, that we are at the parting of the ways. The only standard up to the present which is able

to serve as a guide to the chemist is the training in bacteriology which is served up to the medical student during his University career. It is probably true that the medical man has so many subjects to study that it is not possible to do many of them thoroughly. At any rate, his study of bacteriology is largely confined to the study of a few empirical facts, all severely utilitarian, and all solely concerned with pathogenic organisms. All this may be quite correct if the general practitioner, bacteriologically considered, is to be trained to be a mere machine to supply data to the bacteriological specialist who will then conduct the investigation. A medical student, after he has stained according to Gram, may not feel that he is ready to sit for his examination, but he does feel that he has broken the back of his work. He is tested by his capacity to perform certain mechanical operations, and to identify certain pathogenic organisms in artificial cultures. The object in making these statements is not to deride this course or even to question its wisdom. But when it is automatically assumed that the same kind of training is adequate for the industrial chemist, the matter wears a different aspect. It would be easy enough to put a chemist through a parallel course to make him sufficiently expert at staining operations to cause his friends to exclaim at his cleverness. He could also be taught to make beautiful media for the cultivation of bacteria, and sterilise so well that not a microbe would dare to approach his apparatus. Alas, one could call in an intelligent porter and make him equally expert. As a matter of fact in many laboratories there are laboratory attendants who do this kind of thing much better usually than their superiors. And yet these excellent attendants cannot be dubbed bacteriologists. What makes the bacteriologist is the mental power of co-ordinating these facts in the light of all the other facts that are known from former experience. In short, the bacteriologist must have a scheme of the bacteriological world in his head, and he must be able to place the ascertained facts in their correct relation to this world. A laboratory attendant can never do this: a medical practitioner is somewhat better off because his general training is partly biological. But, in general, he is little better off unless he brings to bear his biological training. Almost unconsciously a course of bacteriological training is judged by a medical man by the standard which holds in a medical laboratory. A very good instance of such a standard was a criticism by a medical reviewer of one of the writer's books that a certain organism used by the writer for instructional purposes "was not much used in the laboratory nowadays." Let the educationist consider the exact import of this silly criticism, and he will see the trend of the reviewer's thoughts. Obviously the reviewer regarded the training of the bacteriologist just as an old-fashioned baker regards the training of his apprentice, the aim being to secure a mechanical deftness in the carrying out of certain bakery operations. It seems to the writer that this mischievous conception must be combated at all costs. It is being combated even in the so-called mechanical trades, and "it is a bit hard," as Mr. Ukridge would say, that such an eminently scientific person as a chemist should be gradually inveigled into an atmosphere in regard to bacteriological matters that is fraught with danger, because of all professions that of a chemist is the one in which it is necessary that he should be freed from the trammels of empirical lore.

It is necessary next to enter upon an aspect of the chemist's training, to which very few chemists have given any thought. It is agreed by most that some study of the microscope should be given to the budding chemist. But note this very essential point. In chemistry, physics and mathematics his training proceeds in one unbroken line from his early schooldays until he finally qualifies at the University or else develops his faculties in the laboratories of an analytical chemist. The point is that the line of his development is unbroken, and thereby he becomes a professional chemist and markedly different from the less fortunate amateur. But does the same hold in respect to the training of the chemist in bacteriological work or in that part of his work where the use of the microscope is involved? That which is held to be of the utmost importance in respect to his training in chemistry, physics and mathematics is held to be unnecessary when the chemist has to deal with objects of microscopic dimensions or when he has to deal with the facts of biological life. The chemist, in spite of his excellent training in the three subjects mentioned, is the most amateurish of persons the moment he begins to handle the microscope, and when he tries his hand at deciphering the facts of life that are presented to him when he examines micro-organisms under the microscope. It is not the chemist who is to blame, it is his education that is at fault. He does not know how to observe, the facts of developmental life history are a closed book to him. His senses record certain impressions; they result in vague perceptions but never in clearly defined conceptions. Does any chemist think that a series of observations in biology that correspond to sets of observations or experiments in chemistry that would only be given to chemists in their fourth year of training, can be accomplished in their first biological year? That is what it amounts to when chemists in their fourth year or at the close of their career in college take out a course in bacteriology without the slightest training in biology. It cannot be done. The result is that when the voice of the tempter becomes insistent, the training of the chemist in bacteriology is apt to degenerate into an attempt to become mechanical experts at certain standardised mechanical operations. That is what the training in bacteriology usually amounts to in the medical student's career, and he is somewhat better off than the chemist, because whilst it cannot be said that he has had a bite at biology, he has had a lick at it. The chemist sees the futility of this kind of procedure in the realm of chemistry. It would be quite feasible to train a laboratory attendant to perform fairly complex operations in chemistry and become quite expert at them—in fact, attendants often perform experiments at the lecture table better than the lecturing professor. But suppose

he chemist were judged by this mechanical skill, e would be the first, and rightly so, to cry out. hat, however, is precisely what the study of bacteriology will amount to in the hands of chemists, nless they can free themselves from the procedure vogue in medical laboratories. Let them face the ct that they must either obtain a preliminary training in certain aspects of biology or else give up the udy of bacteriology except as a pastime. One feels nclined to retort as did Huxley when he was worried by a divine who "put his foot into it every time he opened his month." The retort was: "Go and dissect a frog." So one would say to the chemist: "Go and get a biological training, no matter what the means by which this training is obtained." Of course one does not expect the chemists to go hand-in-hand gathering flowers and trying to find out the technical names for a lot of plants and animals. Old time botany consisted largely in learning the technical names of plants. All this is a thing of the past. Behind all this rubbishy learning of names are vast biological truths corresponding to, say, the laws of chemical union or the principles of osmosis. It is of the utmost importance that some of these biological truths should be known before the student tackles the science of bacteriology. It must be considered that if a course of bacteriology were instituted at a biological centre, it would be given only during the concluding part of the period of training on account of its difficult nature. Why, then, should the chemist be expected to plunge into a course of bacteriology without the slightest preparation in biology to fit him for the task? The result, of course, is that, as already stated, a number of empirical facts are gleaned, and there the matter rests. Again, superficially considered, a training in examining things under the microscope does not appear necessary. A person with good eyes can see just the same as any other person who has equal powers of vision. Every biologist knows the fallacy which is here involved. It confuses sensation with perception. The sensations of both are the same, but oh! how different their perceptions! Books have been written to enable the chemist to identify various objects under the microscope, but very few without a biological training can do more than just identify the grosser objects with something that they have seen depicted in the book. And when attempts are made with very tiny objects like yeasts and bacteria, very disappointing results are obtained. It may well be stated that the industrial chemist has too much on his hands already, and has no time to devote to the study of biology as a preparatory course for the study of bacteriology. In that case the subject should be left alone. Quite apart from the subject of bacteriology it must, however, be confessed that it is hardly to be expected that a modern chemist should forego the powers that the microscope puts into his hands. Even if he means to devote himself to the metallurgical side, for example, in which living organisms play no part, he still needs the training in microscopy.

The final conclusion which the above remarks lead to is this, that a course in microscopy exemplifying the main biological truths, and giving the chemist an insight into the developmental factor in the lives of animals and plants, should precede the study of bacteriology. The specific proposals as to the line which such a course should take and the manner in which it should lead to a second course embracing the study of bacteria, yeasts and moulds will be given in a subsequent article. Finally, the mode in which the bacteriology course should proceed so as to be of most use to the chemist in his subsequent life work will be delineated.

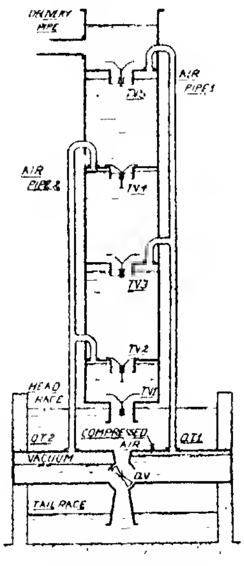
Glasgow

CHEMICAL ENGINEERING AT THE BRITISH EMPIRE EXHIBITION

By Prof. J. W. HINCHLEY

The nine and a-half acres of machinery in the Palace of Engineering alone provide so many exhibits of great importance to the chemical engineer and factory manager that it is difficult to know where to begin. Some of the oldest engineering devices, which are almost forgotten to-day, and the latest inventions for the same purpose are to be seen. The



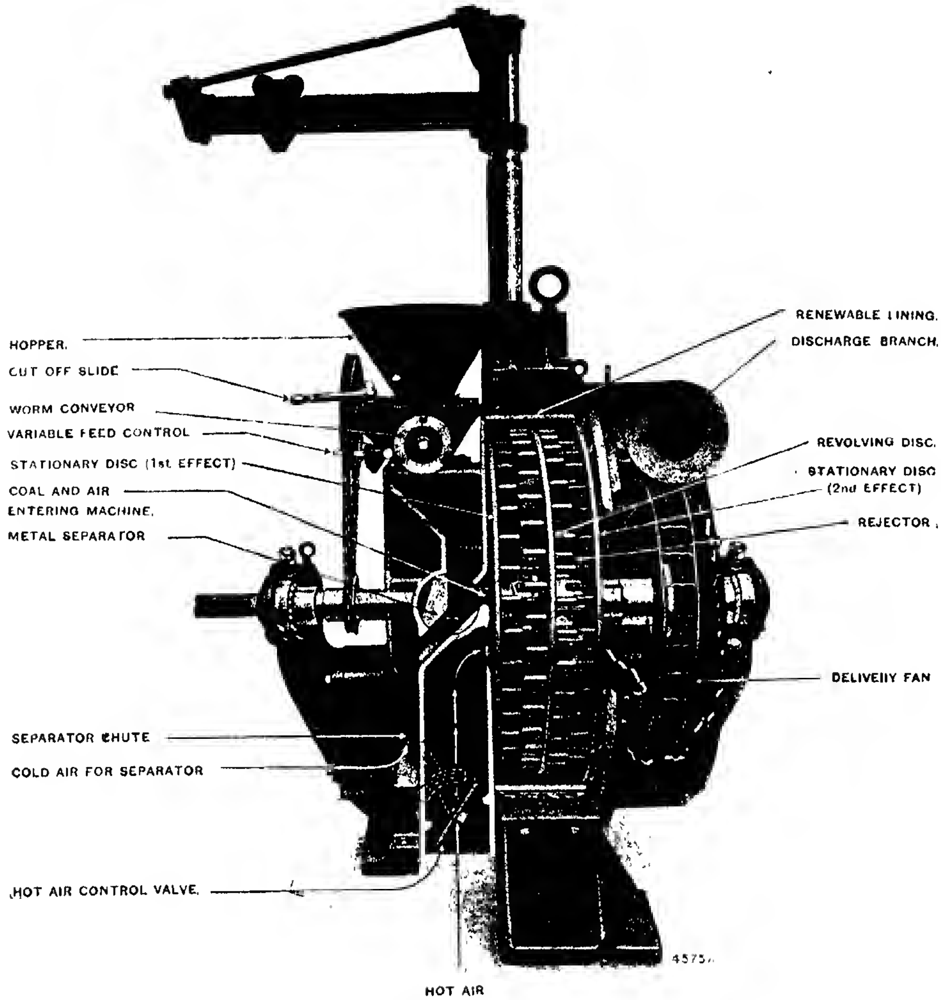
The Hydrautomat

FIG. 1

old-fashioned but really useful hydraulic ram, which may be seen on the stand of Sir W. H. Bailey and Co., has its modern equivalent in the apparatus, (Fig. 1) shown by Hydrautomat, Ltd. It is a pumping device which will work for an unlimited time without expense. A small difference of level may be utilised to raise water to any height by making it produce, in the first instance, compressed and rarified air. Two operating tanks at the base of the machine fill

and empty alternately by means of an automatic valve, and in doing so compress the air in the empty tank and produce a partial vacuum in the full one. Pipes connect the upper part of each tank to alternate compartments in the lifting column, and each partition in this column carries a transfer valve which dips into the chamber below to a depth corresponding to the amount of water lifted during each stroke.

A coal pulveriser, the "Atritor" (Fig. 2), is exhibited by Alfred Herbert, Ltd. In this machine a double pin disc type disintegrator is employed, and the fan is mounted on the same shaft as the rotor of the disintegrator, and ejects the coal dust direct into the furnace for burning. As the material falls from the feeder the induced current of air draws the coal into the disintegrator, but any heavier material



The "Atritor"

FIG. 2

It will be realised that the water in any compartment is forced upwards by the difference in pressure produced in the two sets of pipes. The water thus moves in a series of stages to the highest compartment.

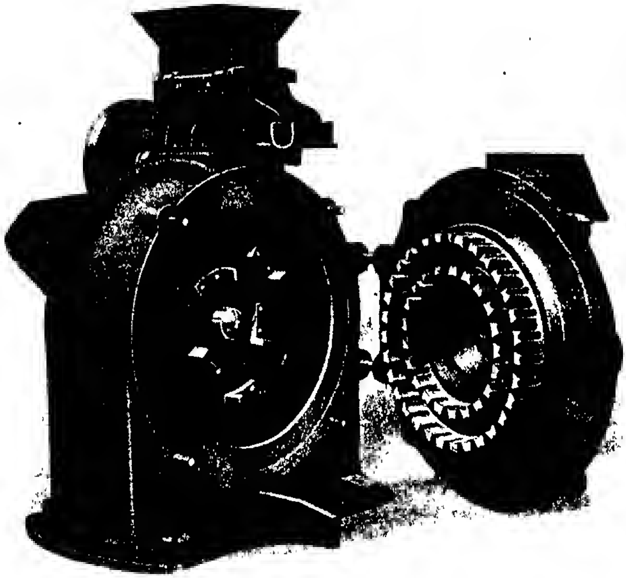
The increased efficiencies or special advantages obtained by using pulverised coal as fuel have led to developments in grinding machinery which, whilst important for the use for which they were designed, are also applicable for other purposes.

drops down a discharge shoot. Provision is made for a supply of hot air to dry the coal as it passes through the machine, and for the addition of small amounts of fuel oil when the coal to be burnt is of very low grade.

The "Impact Grinder" (Fig. 3) of W. S. Barron and Son, Ltd., is interesting on account of the simple method by which a fairly uniform product is obtained. It is not, however, a grinder, but a disc type of

disintegrator, similar to the "Perplex" machine. Any material which does not pass through the screen is raised by the rotor and discharged by the current of air produced, through a slot at the top of the pulverising chamber back again into the feed spout.

The acid-resisting Kitson-Utley rotary pumps may be mentioned. In this pump the casing is machined to a definite curve, so that sliding blades of fixed length, when rotated in a slotted eccentrically placed boss, fit without clearance in all positions. The



The "Impact Grinder"

Fig. 3

A simple "mill-stone" grinder which is worth inspection is to be seen on the same stand.

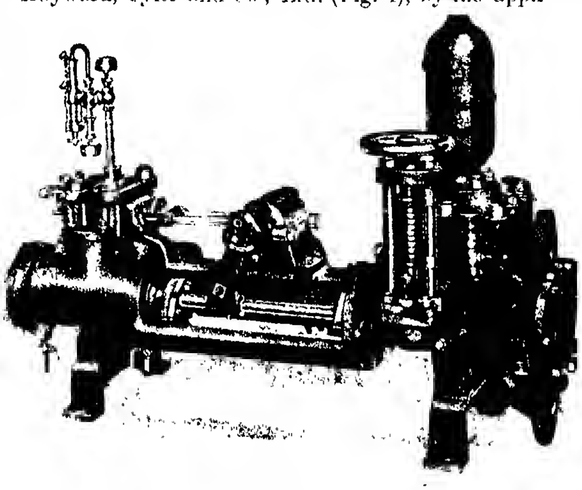
The Hurrell Homogeniser, a variety of colloid mill, may also be worth consideration. The rotor consists of what may be said to be two half width pulleys fixed web to web, and revolving close to an outer jacketted casing. The material to be treated is fed to the centre of the compound pulley, passes between the two webs, and is delivered between the two rims and the casing, where it is subjected to powerful shearing forces. The feed of material regulates the rate of working.

The concrete mixer exhibited by Drummond and Co., Ltd., is obviously suitable for other mixing operations, *e.g.*, furnace charges, batch mixings, etc.

The "Flexala" and "Resiline" centrifugal pumps shown by the Pulsometer Engineering Co., and due to the late Hon. R. C. Parsons, should interest every chemical engineer who has to pump sludge or liquids charged with solids or abrasive materials. The feature of these pumps is the use of a rubber coated impeller with flexible vanes of pliant rubber. The resistance to erosion of rubber is well known. In the "Resiline" pump the whole of the impeller and the interior of the casing is covered with rubber. The resistance to wear of these pumps brings to mind the recent use of rubber linings to ball and tube mills in place of the usual quartzite or metal linings.

pump has proved itself during the last two years; it may be used as a blower or exhauster with success.

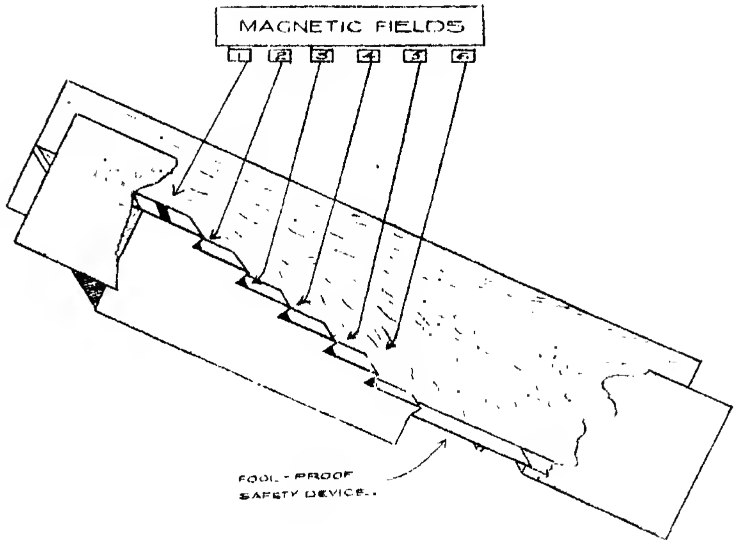
An improvement in the duplex pump shown by Hayward, Tyler and Co., Ltd. (Fig. 4), by the appli-



Duplex Pump with Twells Valve Motion

Fig. 4

cation of the Twells' valve motion is well demonstrated by a pump in work. It differs from the usual valve-gear in the closing of the steam ports; although each piston controls the opening of the opposite valve it closes its *own* valve. A hydraulic pump by work or where shocks may occur; the flaws or blow holes present in cast bodies are absent, and the seatings are made of a hard alloy autogenously united to the working parts of the valve. Drop-forged bodies of valves in special bronze shown by



The "Cascader" Separator

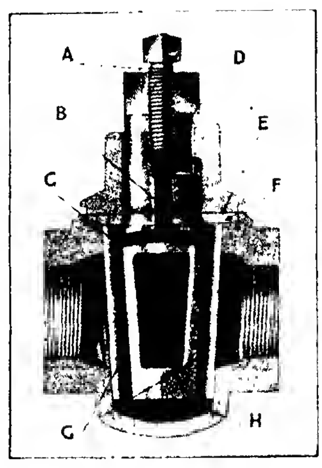
FIG. 5

the same makers and actuated by compressed air is worth attention on account of its value in providing hydraulic water in places where a compressed air service only is available.

New means of transport in factories are always of interest, and the Redler conveyor for grain, flour or powders should be examined. The conveyer is shown at work, and the effective way in which a casing full of flour is moved is very convincing. A chain of simple flat design ⅜ in. thick is carried by sets of sprocket wheels at each end of the conveyor casing. The height of material which may be carried by the chain is equal to the width of the chain. It is in fact a kind of scraper conveyor in which no scraping takes place. It is stated that 4 horse power will convey 50 tons through 100 ft. per hour by means of the Redler conveyor, whilst 20 h.p. is required if a screw conveyor be used. An important improvement in magnetic separators is the "Cascader" (Fig. 5), demonstrated by the Magnetic Separator Co., of Liverpool. The poles of a series of magnets are arranged to form undercut steps in a delivery shoot. At each step a very strong field is produced which holds any shape of iron or steel with remarkable security and certainty. A flap at the last step falls when the current is cut off and diverts the separated iron into a special receptacle.

Valves and cocks are a source of trouble to the chemical engineer, and at times a faulty valve is responsible for the failure or comparative failure of a new plant. The wrought steel valves shown by Victory Valves, Ltd., give confidence in high-pressure

P. D. Mitchell, of Dundee, are also of interest in this connexion when steel is inadmissible. This firm have an interesting exhibit of containers with an ingenious "capsule closing."



The Merco Plug Valve

FIG. 6

The "Klinger" valve is essentially a chemical works valve; it has no seat to corrode and any leakage is readily stopped. A smooth cylindrical

plunger moves through two jointing rings of flexible material, separated by a bush of similar material to that of the plunger, in which are placed passages for the fluid. A gland provides for the constraint of the flexible rings. It will be seen that such a valve will prevent many troubles in chemical plant, to avoid which in some cases two or more ordinary valves are fitted.

The careful design and excellent workmanship shown in the valves of normal pattern shown by J. Blakeborough and Sons, Ltd., deserve attention, whilst their exhibit of the Lundgren-Boyd Rotary Valve, the Edwards automatic stop valve, and the Larner-Johnson hydraulic valves, are of the greatest interest to the water-power engineer. A plug cock that will neither stick nor leak is the attractive claim made for the "Merco" plug valve (Fig. 6), manufactured by the Audley Engineering Co., Ltd. Lubricant ducts are provided in the plug and a lubricant chamber at its base. By means of a screw at the end of the plug, compression of the lubricant takes place, the plug is released and lubricant distributed over it. The feasibility of the claims is obvious. Another cock made by the same firm is provided with recesses in both the body and plug, so that no working surfaces are exposed to the fluids whether the cock is in the open or closed position; any deposit formed cannot therefore affect these surfaces and scoring and jamming are avoided.

(To be continued.)

NOTES FROM CANADA

General Notes

The sugar refineries of Canada, are very active and the export business has been good.

The first unit of the National Cement Co., Montreal, is under construction. It will have a capacity of 900 000 barrels per annum. The company has acquired a large acreage of raw material adjacent to railway and harbour facilities.

The raw fur crop for the last fiscal year was valued at $16,761,597, greater portion being exported. There is no large establishment for the dressing and dyeing of furs in Canada. There are approximately 1000 fox farms in the country.

A company has been formed in Alberta under the name of the Prairie Oils Ltd., for the manufacture of carbon black at High Prairie, Alberta, from the large natural gas wells of the district. The Dominion Government has granted a permit for this purpose, as the wells are located in a district where the gas cannot be economically utilised for heating or lighting purposes.

The Utah-Idaho Sugar Co., one of the largest U.S.A. sugar-beet refiners, contemplates erecting a sugar refinery at Macleod, Southern Alberta. It is at present negotiating with the farmers of the district for a guaranteed production from 6000 acres of beet culture. This is receiving favourable consideration. Many farmers in the adjacent State of Montana have adopted sugar-beet growing and are obtaining good results.

Messrs. Courtaulds, Ltd., have commenced the erection of an artificial silk plant, at Cornwall, Ont. The Foundation Co., of Canada has the contract for the general construction, and the Canadian Vickers that of steel supply.

The Dominion Tar, Chemical and Paper Co., which is sponsored by British interests, represented recently in Canada by the Earl of Dunmore and Sir Harold Botton, has leased land in Toronto, Ont., for the purpose of erecting a factory. Similar sites have been secured in Montreal, St. Boniface and Vancouver, so that the company will possess a chain of works from ocean to ocean.

Canadian Company News

Notwithstanding depression in the steel industry at the early part of last year, the annual financial statement of the Steel Co., of Canada, shows satisfactory earnings for 1923. These earnings amounted to $3,284,467, after providing for repairs, maintenance and improvements and providing for inventory reserve and income tax for 1923, but before making provision for depreciation and bond interest. These latter disbursements were- depreciation reserve $377,651, bond interest $441,962 and dividends on shares $1,259,741, leaving the sum of $627,875 to be credited to profit and loss account.

There have been no new developments in the affairs of the Bay City Pulp and Paper Co., or the Saguenay Pulp and Power Co., which have been in the past, more or less, under the direction of Sir Frederick Becker, of London. The financial report of the Saguenay Co., shows a deficit of $183,826 in 1923, compared with a deficit of $419,579 the previous year. The financial condition of the Becker concerns, in Canada, is attributed to poor management and direction.

The annual statement for the year 1923 of the Consolidated Mining and Smelting Co., of Canada, is very satisfactory, notwithstanding the power shortage which prevented a full realisation of the earning potentialities of the concern. After all charges, including those for depreciation and taxes which are both about double what they were in 1922, there is a net profit of $1,681,162 available for common stock, as compared with $975,449 in 1922, and $270,722 in 1921. This sum is equivalent to $3.98 per share on the stock, or 15·9 per cent. on the $25· par value of shares.

The asbestos mines of Quebec have had a lean year, and one of the larger companies has gone into liquidation. The annual report of the Asbestos Corporation of Canada Ltd., very well illustrates the condition of these industries. The operating profits for the year, after provision for income tax, were $368,936, as compared with $727,093 in 1922, with no write off for depreciation and depletion. After curtailed dividend distribution of the year, a surplus of only $22,230 existed. It is stated the company intends to try the wet process for the extraction of asbestos instead of separating the fibre by screening. The process is claimed to give increased production of asbestos, at less cost and improved quality.

FORTHCOMING EVENTS

June 11. FARADAY SOCIETY AND THE TEXTILE INSTITUTE, at the British Empire Exhibition, Wembley, in Conference Hall No. 4, from 2.30 p.m. to 6.30 p.m. Various papers will be read and discussed.

June 11 to 13. SOCIETY OF DYERS AND COLOURISTS. Annual dinner on June 11 at the Hotel Victoria, Northumberland Avenue, London, S.W. 1. Conference on June 11 and 12 at the British Empire Exhibition, Wembley; on June 11 (3 p.m.) J. R. Hannay will give "An Historical Survey of Dyeing and Calico Printing," and on June 12 (11 a.m.) Prof. A. G. Green, F.R.S., will speak on "Modern Methods of Dyeing." River outing (cost 15s. per person) to Windsor on June 13. Application for tickets should be made to the Society of Dyers and Colourists, 30, Pearl Assurance Buildings, Bradford.

June 11. BRITISH EMPIRE EXHIBITION, WEMBLEY. Conferences on "Heredity as the Basis of National and Industrial Efficiency." Also on June 18 and 25.

June 12. CHEMICAL SOCIETY. Meeting to be held in the Theatre of the Royal Institution, 21, Albemarle Street, W. 1, at 5.30 p.m., when the Faraday Lecture, entitled "Atomism in Modern Physics," will be delivered by Prof. R. A. Millikan.

June 13. UNIVERSITY OF LONDON, University College, Gower Street, W.C. 1, at 5.30 p.m. First of Three Lectures on Physics by Prof. R. A. Millikan. Lectures 2 and 3 to be delivered on June 17 and 19, respectively.

July 15. THE INSTITUTE OF CHEMISTRY STUDENTS' ASSOCIATION (LONDON). Visit of Chemical Students to Wembley. At 9.45 a.m. an Inaugural Meeting will be held at University College, Gower Street, W.C. 1, at which the President of the Institute, Prof. G. G. Henderson, LL.D., F.R.S., will take the chair. Mr. W. J. U. Woolcock, C.B.E., General Organiser of the Chemical Section of the Exhibition and President-elect of the Society of Chemical Industry, will explain the objects of the exhibits and the special features of interest. Prof. W. P. Wynne, C.B.E., F.R.S., President of the Chemical Society, hopes to support the speaker at the meeting. The cost of the visit, including return ticket to Wembley, entrance to the Exhibition, and ticket for luncheon, will be 5s. Further information can be obtained from Mr. G. S. W. Marlow, 30, Russell Square, London, W.C. 1, and applications should be made not later than June 28.

Sept. 8 to 11. INSTITUTE OF METALS. Annual Autumn Meeting, to be opened at the Institution of Mechanical Engineers, when W. M. Corse, S.B., will deliver the third annual Autumn Lecture. On September 9 the morning will be devoted to reading and discussion of papers, followed by luncheon at the Connaught Rooms, Kingsway, the afternoon to be spent at the British Empire Exhibition. On September 10 further papers will be presented for discussion, the afternoon being devoted to visits to works. A reception will be held in the evening at the National Physical Laboratory, Teddington. A detailed programme will be issued in August.

SOCIETY OF CHEMICAL INDUSTRY

ANNUAL GENERAL MEETING, 1924

PATRON: H.M. THE KING

In accordance with the provisions of by-law 68 notice is hereby given that the Annual General Meeting of the Society of Chemical Industry will be held in the Arts Theatre, The University, Liverpool, on Wednesday, July 9, 1924, at 10.30 a.m.

The following is the official Programme :—

Tuesday, July 8, 9.0 p.m. Informal Reception by the President and the Local Committee at the Midland Adelphi Hotel.

Wednesday, July 9, 10.30 a.m. Annual General Meeting in the Arts Theatre, The University, and Presidential Address, "A Neglected Chapter in Organic Chemistry: The Fats." 2.30 p.m. Visit to White Star Liner, "Cedric," and tea on board, by invitation of the White Star Line. 8.30 p.m. Reception and Dance in the Town Hall, by invitation of the Rt. Hon. The Lord Mayor of Liverpool (Arnold Rushton, Esq.).

Thursday, July 10, 10.30 a.m. (hour subject to alteration). Messel Memorial Lecture by the Rt. Hon. Viscount Leverhulme, in the Arts Theatre, and presentation to the Lecturer of the Society's Messel Medal for 1924, 12.30 p.m. (hour subject to alteration). Visit to the Works of Messrs. Joseph Crosfield and Sons, Ltd., Warrington. Luncheon by invitation of the Directors. Inspection of the Works of Messrs. Joseph Crosfield and Sons, Ltd. Cost of travelling, 5s. 7.30 p.m. Annual Dinner, in the Midland Adelphi Hotel. Tickets, exclusive of Wines, 12s. 6d.

Friday, July 11, 10.0 a.m. Business Session in the Physics Lecture Theatre, The University. 1.0 p.m. Luncheon at the Midland Adelphi Hotel, by invitation of the Chairman and Directors of The United Alkali Co., Ltd., followed by visit to Works of The United Alkali Co., Ltd. Cost of travelling, 3s. 6d. 7.30 p.m. Dinner at Port Sunlight, by invitation of the Chairman and Directors of Messrs. Lever Bros., Ltd. Cost of travelling, 2s. 6d.

Saturday, July 12. About 9.30 a.m. (details later) Visit to Lake Vyrnwy. Inspection of the Liverpool Corporation Waterworks (limited to 150). Luncheon and tea, by invitation of the Water Committee of the Corporation of Liverpool. Arrive Liverpool about 9.30 p.m. Cost, dinner on train included, 25s.

Unofficial Excursions. Tickets to be booked in Liverpool at Reception Room :—Chester, River Dee and Eaton Hall; Isle of Man; Llandudno and Beaumaris (sea); Lake District (two days).

Members intending to attend the meeting are asked to send their applications, accompanied by the appropriate remittance, as early as possible to Mr. E. Gabriel Jones, City Laboratories, Mount Pleasant, Liverpool, to whom all inquiries relating to private hospitality, railway travelling and other matters connected with the meeting should be addressed.

A ballot list for the election of Members of Council has been despatched to each member entitled to vote.

J. P. LONGSTAFF,
General Secretary

OBITUARY

Dr. G. H. BAILEY

George Herbert Bailey was born on May 17, 1852, at Barnard Castle, in the County of Durham. From early years he was particularly attracted by scientific pursuits. In 1879 he graduated Bachelor of Science, London University, and from 1880 to 1882, was science master at Tattenhall College, near Wolverhampton, resigning this appointment to become a student at the Owens College, Manchester, where he took the second and third year's courses in Chemistry and Physics, at the same time carrying out spectroscopic researches under Prof. Schuster, also researches on chlorophyll with Dr. Schunck, and on vanadium compounds in the Laboratory of Prof. H. E. Roscoe. Whilst at Owens College he was awarded the Dalton Chemical Scholarship.

From 1884 to 1885 he continued his studies at Heidelberg, under Profs. Bunsen, Kopp, Quincke and Rosenbusch, obtaining at the end of this period the D.Sc. (London) and Ph.D. (Heidelberg).

He now became demonstrator and lecturer in Chemistry at the Owens College remaining there for the long period of 24 years, during which time he carried out a considerable number of researches.

The technological side of chemistry appealed to him particularly, and he was associated from early days with the Manchester Section of the Society of Chemical Industry, of which Section he was Chairman in 1905–7. During his residence in Manchester he undertook a considerable amount of consulting work, particularly on behalf of the Corporation of Manchester.

In April, 1909, he was appointed Chief Chemist to the British Aluminium Company, Ltd., his headquarters being at the Kinlochleven works of the company. In this appointment he found considerable scope for his activities until 1920, when, at the age of 68, the company permitted his retirement, retaining him however, as their Advisory Chemist up to the time of his death. Two attacks of pneumonia, in 1906 and 1909, had left a heart weakness, which, though it had troubled him comparatively little in recent years, nevertheless persisted, and a day spent in too great activity in his garden at Datchet, that he loved so much, appears to have been responsible for a heart seizure which brought to a sudden termination a life in which one can truthfully say there had been no idleness. He leaves a widow, three sons and a daughter; his eldest son is a squadron leader in the Royal Air Force, the second is in Rhodesia, and the third in New Zealand.

His published words include: -1881: Componenten der absorption spectrum erzeugenden seltenen erden (*Ber.*, 21, 1520). 1884: Some vanadates of the ammes (*Jour. Chem. Soc.*, 1884, 690). 1886: Separation and estimation of zirconium (*Jour. Chem. Soc.*, 1886, 149 and 181), also (*Annalen*, 232, 352); Analysis of coppite (*Jour. Chem. Soc.*, 153); (*Annalen* (232), 357) 1887: The double sulphate of lead and aluminium (*Jour. Soc. Chem. Ind.*, 1887, 415); Determination of atomic weight by means of the normal sulphate (*Jour. Chem. Soc.*, 1887, 676 T); Silver suboxide (*Chem. News.*, 55 and 263), and with C. J. Fowler, Silver-suboxide (*Jour. Chem. Soc.*, 416 T and 54 P); Interpenetration of absorption spectra (*Jour. Chem. Soc*, 141 T); Atomic weight of zirconium (Brit. Ass., 1887); Absorption spectra of rare earths (Brit. Ass., 1887); Absorption spectra of the haloid salts of didymium (Brit Ass., 1887); Components of the rare earths yielding absorption spectra (*Ber.* 1887, 2769 and 3325); Temperatures at which various sulphates undergo decomposition (*Jour. Chem. Soc.*, 1887, 100 P.); Influence of mass on chemical decomposition (*Jour. Soc. Chem. Ind.*, 91). 1889: Estimation and occurrence of sulphur in coal (*Jour. Soc. Chem. Ind.*, 360); On the vitrified cement from an ancient fort (Memoirs, Manc. Lit. and Phil. Soc.); Method for the separation and estimation of zirconium (*Annalen* (232), 3). 1890: "With A. A. Read:" The behaviour of the more stable oxides at high temperatures (Brit. Ass. 1890); "With J. C. Cain": A method of quantitative analysis (Brit. Ass., 1890); The spectra of the haloid salts of didymium (Brit. Ass., 1890); "With A. Hopkins:" The behaviour of the more stable oxides at high temperatures (*Jour. Chem. Soc.*, 269 T). 1890: The effect of noxious gases on plant life (Manc. Field. Naturalists. Soc., 56). 1891: A report on the atmosphere of Manchester (Manc. Field Naturalists Soc.). 1892: Conditions affecting plant life in a town atmosphere (Brit. Ass.).; Air impurities of towns (*Jour. Soc., Chem. Ind.*, 769); "With Lamb": The atomic weight of palladium (*Jour. Chem. Soc.*, 745 T). 1893: On the liability of pine trees to lightning strokes (Mem., Manc. Lit. and Phil.). 1894: Some aspects of town air as contrasted with that in the country. (Mem., Manc. Lit. and Phil.); The stability of oxides considered in relation to the periodic law (*Jour. Chem. Soc*, 315 T.); The volatility of salts during evaporation (*Jour. Chem. Soc.*, 445). 1903: "With Hart": The manufacture of sulphuric acid by the chamber process (*Jour. Soc. Chem. Ind.*, 538). 1905: Higher education in the chemical industry (*Jour. Soc. Chem. Ind.*, 1205). 1910: A record of analysis (*Jour. Inst. Met.*, 1. 210); Analysis of aluminium and its alloys (*Jour. Inst. Met.*, 1, 151). 1913: The corrosion of condenser tubes (*Jour. Inst. Met.*, 71). 1916: Electric furnaces applied to non-ferrous metallurgy (*Jour. Inst. Met.*, 305); on the third report of the corrosion research committee (*Jour. Inst. Met.*, 1, 185). 1917: The effect of heat on the rate of softening of cold rolled aluminium sheets (*Jour. Inst. Met.*, 11, 164). 1919: The action of hard industrial waters on aluminium (*Jour. Inst. Met.*, 1, 187); On the fourth report of the Corrosion Research Committee (*Jour. Inst. Met.*, 1, 234). 1920: The corrosion of aluminium (*Jour. Inst. Met.*, 2, 404); The rate of corrosion of aluminium (*Jour. Soc. Chem. Ind.*, 118 T).

Dr. Bailey was the author of the following textbooks:—First stage Inorganic Chemistry, the New Matriculation Chemistry, Elements of Quantitative Analysis, Tutorial Chemistry. Part 2, "Metals and Physical Chemistry," Advanced Inorganic Chemistry.

The above notice has been compiled at the request of the Manchester Section and the writer is indebted to Mr. T. Lewis Bailey, his brother, for most of the above information.

ATOMS AND ISOTOPES*

By Dr. F. W. ASTON

That matter is discontinuous and consists of discrete particles is now an accepted fact, though it is not obvious to the senses on account of the extreme smallness of the particles. Some idea of their size and numbers can be gained by the hypothetical division of a piece of matter into smaller and smaller pieces until the ultimate atom is reached. For this purpose a model decimetre cube of lead is taken and cut in such a manner that after each operation a similar cube of half the linear dimensions and one eighth the volume results. Modern science shows that this operation can be repeated no less than 28 times before the ultimate atom of lead is reached, and that the number of atoms in the original cube is so enormous that placed in a string as close together as they are in the lead they would extend over six million million miles. Again, if an ordinary evacuated electric light bulb were pierced with an aperture such that one million molecules of the air entered per second, the pressure in the bulb would not rise to that of the air outside for a hundred million years.

Dalton, in his atomic theory, postulated that "Atoms of the same element are similar to one another and equal in weight," a simple and definite conception which has been of inestimable value in the development of chemistry. A little later Prout suggested that the atoms of all elements were made of atoms of a primordial substance which he endeavoured to identify with hydrogen. If Dalton and Prout were both right the chemical atomic weights should all be whole numbers, hydrogen being unity. Chemical evidence was against this, and Prout's theory was abandoned for the time. We cannot test the truth of Dalton's postulate by chemical methods since these require countless myriads of atoms, and, therefore, only give a mean result.

The weights of individual atoms can be investigated by means of the analysis of positive rays and the early experiments of Sir J. J. Thomson suggested that one element—neon—had atoms of two different weights but the method of analysis was not accurate enough to prove the point. The requisite accuracy has been obtained by means of an instrument called the "mass-spectrograph." In this the charged atoms in a beam of positive rays are sorted out according to their weight by means of magnetic and electric fields so that they strike a photographic plate at different points. A mixture of atoms of different weights will give a series of focussed lines called a mass spectrum and the relative weights of the atoms can be calculated from the position of their lines to an accuracy of 1 in 1000.

As the result of this analysis it has been shown that neon (Atomic Weight 20·20) is a mixture of atoms of weights 20 and 22. These constituents have identical chemical properties and are called "isotopes." Chlorine (At. Wt. 35·46) is a mixture of isotopic atoms of weights 35 and 37. About half the elements so far analysed are mixtures and some are very complex. Thus krypton has six, tin at least seven and xenon possibly nine constituent isotopes. Recently, by means of the method of "accelerated anode rays," the work has been extended to many metals and already some fifty of the eighty-four known non-radioactive elements have been analysed into their constituent isotopes or shown to be "simple."

Most important of all is the fact arising out of these measurements that all true weights of atoms can be expressed as whole numbers to a very high degree of accuracy. This remarkable generalisation known as the "whole number rule" has removed the last obstacle in the way of a simple unitary theory of matter. We now know that Nature uses the same bricks in the construction of the atoms of all elements, and that these standard bricks are the primordial atoms of positive and negative electricity, protons and electrons.

According to the nucleus theory of the atom first suggested by Sir Ernest Rutherford, which has led to such wonderful advances recently in the hands of Professor Bohr, all the protons which are much heavier than electrons, are packed with some of the electrons in a central nucleus or sun round which circulate the remaining electrons like planets in orbits. The protons and electrons are so minute compared with the atom itself that it is difficult to indicate their numerical relations. If we were to construct a scale model of the atom as big as the dome of St. Paul's we should have some difficulty in seeing the electrons, which would be little larger than pin heads, whilst the protons would escape notice altogether as dust particles invisible to the unaided eye. Experimental evidence leaves us no escape from the astounding conclusion that the atom of matter as a structure, is empty, empty as the solar system, and that what we measure as its spherical boundary really only represents the limiting orbits of its outermost electrons.

All the chemical and spectroscopic properties of an atom depend on the movements of its planetary electrons, and these in their turn depend on the positive electric charge on the central nucleus. In the case of isotopic atoms the net positive charge on their nuclei is the same, giving identical chemical properties but the total number of protons is different, giving different atomic weights.

Transmutation of one element to another can only be achieved by the disruption of the nucleus. This requires enormous forces, but by the bombardment of atoms by swift alpha particles Rutherford has succeeded in breaking up the nuclei of several of the lighter elements. This transmutation only takes place as the result of a direct hit on the nucleus, the chance of which is only one in many millions. The quantity of matter so transmuted is indeed almost inconceivably small, but it is the first step towards the release and control of the so called "atomic energy." We know now with certainty that four neutral hydrogen atoms weigh appreciably more than one neutral helium atom, though they contain the same units, 4 protons and 4 electrons. If we could transmute hydrogen into helium matter

* May Lecture, delivered before the Institute of Metals, on May 4.

would, therefore, be destroyed and a prodigious quantity of energy would be liberated. The transmutation of the hydrogen contained in one pint of water into helium would set free sufficient energy to propel the Mauretania across the Atlantic and back at full speed. With such vast stores of energy at our disposal there would be literally no limit to the material achievements of the human race.

AMMONIUM PERCHLORATE

ROYAL COMMISSION ON AWARDS TO INVENTORS

This Commission heard on May 26 and June 2 the claims by Messrs C. W. Bailey, H. S. Denny, A. J. Dunk, J. A. Cresswick, R. Young, J. G. Williams, and A. T. Jefferis for awards in connexion with the manufacture during the war of ammonium perchlorate at Langwith in Derbyshire. The hearing was before Mr. Justice Tomlin, the chairman, Mr. F. Norton, C.B.E., K.C., and Mr. A. Chaston Chapman, F.R.S. Several of the claimants appeared in person; Mr. Whitehead, K.C., and Mr. Courtney Terrell appeared for the Crown. Ammonium perchlorate was, in small quantity, used during the war as an explosive, but it is fairly easily detonated and seems to have been less suited for marine mines than for quarry work, where its use is well known. It has for many years been manufactured by Mr. Carlson in Sweden, and when the British Government decided to manufacture in this country it obtained from Mr. Carlson's firm full details of the manufacture of ammonium perchlorate by mixing solutions of sodium perchlorate, prepared electrolytically, and ammonium sulphate. Solubility curves of ammonium perchlorate and sodium sulphate are said by the Crown to have been supplied by Mr. Carlson's firm. The Langwith factory was a difficult problem and the Government sent a number of trained and capable chemists and chemical engineers to put it in order and manufacture economically. The claimants after many difficulties succeeded in making a considerable quantity of ammonium perchlorate and they claim that the improvements made on the Carlson process deserve special recognition. The Crown claims that such improvements as were made could have been thought out by any competent and skilful chemists who were supplied with the necessary information and that the claimants, though they did good work, did merely that for which they were employed and paid. The case is not yet completed and is being heard *in camera*. It is understood that the improvements in respect of which awards are claimed are all for methods of separately crystallising out the sodium sulphate and ammonium perchlorate.

Prof. O. Hahn has been invited to succeed Prof. M. Bodenstein in the chair of physical chemistry in the Hanover Technical *Hochschule*.

THE INSTITUTE OF PHYSICS

At the Annual General Meeting held on May 26 Sir Charles A. Parsons, K.C.B., F.R.S., was re-elected President. The Vice-Presidents are Prof. W. H. Eccles, F.R.S., Mr. C. C. Paterson, Dr. E. H. Rayner, and Sir Napier Shaw, F.R.S. Sir Robert Hadfield, F.R.S., is Treasurer, and Prof. Alfred W. Porter, F.R.S., Honorary Secretary.

From the Annual Report it appears that the demand for highly trained and qualified physicists at present exceeds the supply. The Report deals at some length with the new monthly *Journal of Scientific Instruments*, which is being produced by the Institute, and edited at the National Physical Laboratory. It also refers to the Lectures on Physics in Industry, which are being delivered under the auspices of the Institute, and a second volume of which will shortly be published by the Oxford University Press. It is pointed out that the publication of these lectures and their circulation among manufacturers should do much to promote one of the main objects of the Institute, which is to urge the importance of physics in industry, and to encourage the employment of physicists qualified to understand where and how physical principles and knowledge may be utilised in increasing the efficiency of existing processes, and in the development of new applications.

ACADÉMIE DES SCIENCES

During the meeting on May 19, Prof. Richet described a new treatment of tuberculosis by the juice of pure, dried, and raw meat, a method suggested by the fact that the reparation of the tuberculous organism takes place by the reconstruction of muscular tissue disorganised by the disease. Monsieur G. Bertrand described a method for "stoving" cocoons, in which the action of heat was replaced by that of chloropicrin which ensured the death of the pupa without harming the silky envelope. Monsieur de Broglie described a method of determining the wavelengths of γ rays by their photo-electric effect. Monsieur Breton communicated a paper by G. Kimpflin on the permeability of synthetic resin to infra-red rays. A plate of bakelite, 5 mm. thick, allowed the passage of 35 per cent. of the rays, and the introduction of two per thousand of ferric chloride reduced the transparency by one per cent. The permeability of a "bakelised" plate of paper of the same thickness was 17 per cent., whereas under similar conditions, that of a plate of ebonite was three per cent. The author hopes by reducing the thickness of the plate of resin, and by compensating the slightest mechanical resistance by introducing a suitable charge, to increase the permeability to the infra-red, and to obtain results of interest to industry.

During the meeting on May 26, MM. Lumière described the results of developing silver bromide photographic plates after fixation. The method is long, but has the advantage that development can be carried out in daylight and gives a negative with a finer grain. Prof. Moureu and C. H. Dufraisse described further work on oxidation catalysis utilising free oxygen. The authors emphasised the theoretical

importance of the catalytic action of sulphur and its compounds, not only because of its direct theoretical consequences, but also because of its bearing on biology. In fact, according to recent work, sulphur appears to play a most important part in oxidations in the living body. Monsieur Schloesing described the influence of soil bacteria on plant life, and Prof. Urbain described an anomaly observed in the reduction of bichloride of mercury by sodium formate, which was of considerable theoretical interest. Prof. Le Chatelier communicated a note by Monsieur Peczalski, describing a new observation on salts in metals. MM Desgrez, Bierry and Ratherry described further work on diabetes, showing that the quantity of fat to be used in the diet for diabetic patients should be regulated according to the chemical structure of the fats, and to the relative proportion of the proteins and carbohydrates in the diet. Each individual needs a certain characteristic amount of fat, which is usually small in serious cases of diabetes. Insulin increases the absorptive capacity for fats, permitting a better utilisation of the carbohydrates.

THE BRITISH CHEMICAL AND DYESTUFFS TRADERS' ASSOCIATION, LTD.

The first annual meeting was held in London on May 15, eighty-five representatives being present from various parts of the country. In submitting a report of the first year's work, the chairman, Mr. Victor Blagden, said that previously there had been two associations having the same objects. So as to present a united front to the Government, the manufacturers and the consumers, an amalgamation was effected, the result being the present trade organisation, now registered as a non-trading concern. Roughly 36 new members had been elected during the year and further applications were promised. There were now 128 members, whilst only 20 firms had discontinued membership, and considering the trade depression, this was very satisfactory. Increased membership was required to provide for increased activities. The Association was a non-trading concern, but when chemical or dyestuffs traders' interests were unfairly encroached upon, or when any point of principle was raised affecting their interests, either by a Government Department or by some commercial or industrial interest, the Association was prepared to offer resistance. Valuable assistance had been rendered to members in connexion with the Reparations Recovery Act. In numerous cases the Association obtained satisfactory settlements for members in contesting Customs' claims for reparations levy on goods that were not liable. The committee was not satisfied with the attitude of the Board of Trade towards merchanting interests in respect of dyestuffs. It was unfortunate that the Board of Trade refused to publish particulars of all licences granted. The importance of the various consuming industries seemed to have been lost sight of altogether. The Board of Trade and the Licensing Committee appeared to be willing to inflict any handicap involving the production of inferior finished goods so long as they could, by refusing to grant import licences, push unsatisfactory home-made colours. It was difficult to understand why the Association's request for representation on behalf of dyestuff traders on the Licensing Committee was so persistently refused when it was remembered that over 75 per cent. of the applications for licences came from merchants. The committee had submitted a memorandum regarding the proposed agreement between the British Dyestuffs Corporation and the Interessen Gemeinschaft. Lists of reparation colours had been issued to members, but despite the approval of the consumers, it was not possible to induce the Board of Trade to introduce a special discount to merchants purchasing supplies from reparation stocks, for re-sale. Much work had been done in relation to Part I of the Safeguarding of Industries Act, and the Customs had been persuaded to accept invoice values and not to assess the value of dutiable goods on their own estimate. He (Mr. Blagden) had no comment to make on the desirability of protecting certain essential industries, but he had no hesitation in stating from close and continued experience, that Part I of the Key Industries Act was doing a great deal more harm to the trade of the country, especially to re-export business, than was necessary in order to provide a shelter for such industries. It had cut us off completely from the freedom of international trade in chemicals in which we had previously played a leading part, and this country had lost its place as the best source of supply for every and any chemical whether made here or not. Many cases of hold-up and delay in clearing goods through customs had been dealt with, and an attempt was being made to induce the Treasury to introduce a system of "bonding" of goods liable to Key Industry duty. In general commercial matters the Association had been active. It had dealt with the question of the right of wharfingers to put a general lien on goods. Action had been taken regarding the revision of railway freight rates and negotiations were in progress for the reduction of the Port of London Authority charges for chemicals. A great deal of press propaganda had been carried out and effective work had been performed with the aid of the Association's parliamentary machine.

In proposing a vote of thanks to Mr. Blagden, Mr. F. T. T. Reynolds expressed his appreciation of the work performed by him as their first chairman, and pointed out that organisation was of vital necessity. Manufacturers and consumers had realised this long ago, but traders had only come together recently and had leeway to make up. The trader was appreciated as an indispensable link in the chain of trade. Great Britain was the leading trading country, not only because it was the largest producer or the largest consumer of essential commodities, but because it was the largest trader. Chemicals and dyestuffs were indispensable in times of peace or of war, and the Association had to emphasise the further truth that efficient and effective distribution was the bridge between producer and consumer, and that the trader provided that bridge much more economically and effectively than irresponsible officials.

CORRESPONDENCE

THE HISTORY OF THE GAS PROCESS

Sir,—With regard to your interesting short editorial note in the issue of May 30, concerning the history of the gas process, perhaps you would allow me to give you—as concisely as possible—the facts with regard to the early history of this industry.

The evolution of gas from decaying vegetable matter had been known for centuries, and in 1600 for example, Van Helmont, then resident in Brussels, observed that coal "did belch forth a wild spirit or breath," and the word "gas" itself seems to have been first used by this famous Dutch chemist.

The earliest account of illuminating gas given off by coal is that of Thomas Shirley in the "Philosophical Transactions" of 1667, who noticed (very appropriately) that gas was being issued from a spring near Wigan. The first man who definitely prepared a gaseous product by the carbonisation of vegetable matter, including coal, was Robert Boyle in 1691, and in 1726 Stephen Hales mentions early experiments in this direction in his publication, "Vegetable Staticks." The Rev. John Clayton, Dean of Kildare, whom you mention, was also one of the earliest investigators, and he showed that the inflammable gas given off by the spring at Wigan was really due to the coal underneath. He then heated coal in an open vessel and there is an account of his experiments in the "Philosophical Transactions" of 1739.

Coal was first carbonised on a commercial scale merely for the production of coke, and not for gas at all, at the iron works of the Prince of Nassau-Saarbrucken at Sultzbach, and this process is described in detail by the French author, De Gensanne, in his book printed in Paris in 1770. Also the results of experiments on the distillation of coal were published by Watson in 1781, and the Earl of Dundonald interested himself in the matter, as you state, whilst in 1784 Professor J. P. Minckelers suggested the use of gas for filling balloons.

Indisputably, however, the real pioneer of the gas industry, that is the systematic carbonisation of coal or other vegetable material for the production of gas on a practical scale, was William Murdoch, who was born in 1754 at the village of Lugar in Ayrshire. He began to experiment with the carbonisation of shale and coal when he was a boy, and as a matter of fact there was a small outcrop of shale in his father's cabbage garden. He seems to have commenced these experiments about 1770.

As is well known, he became one of the chief men of the very remarkable staff that Boulton and Watt were able to get together, and for a number of years was their engineering representative in Cornwall. He continued his experiments with gas and in 1792 lighted his house at Redruth with coal gas, which was the first building in the world to be illuminated in this way, and the house is still shown to visitors. James Watt, however, not for the first time in his career, showed an utter lack of imagination in the matter and did his best to discourage Murdoch in every possible way, whilst he also prevented him from continuing his experiments on the locomotive. Incidentally, Murdoch seems to have been the first man in the world to have ever constructed a steam-driven model locomotive, although because of Watt's influence, already mentioned, the work was abandoned. The real pioneer of the steam locomotive is Richard Trevithick, who was unquestionably the greatest engineer in the world, and it is hopeless to get the ordinary man to understand that Stephenson was not the pioneer of the locomotive, but that Trevithick constructed the first steam railway in the world in Wales years before Stephenson was ever associated with locomotives.

Murdoch was subsequently appointed manager of Boulton and Watt's factory in Birmingham, and continued his experiments in spite of Watt, lighting the factory throughout with gas in 1802, the first industrial establishment to be lighted in this manner, the occasion being the celebrations for the peace of Amiens. He then began to supply gas plant to factories, and the first factory to be lighted—apart from the Birmingham establishment—was the cotton mill of Messrs. Phillips and Lee in Manchester in the year 1805, which was fitted with a complete gas plant and 900 gas burners. Murdoch described this installation in the most lucid and detailed manner before the Royal Society of Arts in 1808, and the account can of course be read in their journal, whilst at the same time he was awarded for this paper the Society's Rumford Gold Medal. Murdoch's work on the gas process is almost incredible, and his retorts and gasometer, for example, which are still in existence in Birmingham, might be comparatively modern productions.

Quite independent of this work of Murdoch's, the gas process was also developed in France by the famous Phillippe Lebon, who was an engineer in the service of the French Government (Department of Bridges and Roads), and who seems to have commenced his work—using sawdust in place of coal—about 1791. He completed his investigations by 1799, and caused a great sensation in France in 1801 by lighting his house in the Rue St. Dominique, Paris, with gas. Lebon, of course, met with the usual fate of almost all great men, and after being subjected to petty persecution and derision for the greater part of his life, came to a miserable end, being as a matter of fact stabbed to death in mistake for Napoleon, whom he strongly resembled in appearance.

Finally, although I do not want to make this letter too long, I should like to add a few words about the immortal Winsor (whose name was spelt indiscriminately as Winsor, Winzer, or Wintzler), a German born in Moravia, and who first of all travelled from Frankfort apparently to try to come to some business arrangement with Lebon. The latter very wisely would have nothing to do with him, and Winsor therefore came to London to start a gas lighting company, since he writes in one of his pamphlets:—

"The thought of introducing the discovery for the advantage of the British realm struck me like an electric shock."

He took up his quarters in 1806 at the Star and Garter Hotel, 97, Pall Mall, a site which is now occupied by the Carlton Club, and his efforts to establish a gas industry by means of lectures, demonstrations and pamphlets were one of the sensations of England. The whole episode, which of course has its humorous side, is almost incredible, and to give one example, Winsor promised to anyone who would subscribe to his gas company that he would give them a profit of 6000 guineas per year for every 7 guineas invested (!!). 17,000 shares on these lines were sold in 10 days, rising from one guinea at par to 7 guineas per share, whilst it was reputed that they would rise to 100 guineas, and according to one letter of the period Pall Mall was blocked with people in carriages, on horseback, and on foot rushing to invest. Whether Winsor was stark crazy or only a mountebank is not clear, but at any rate it was due to his efforts that gas lighting commenced in Great Britain, and Pall Mall was the first public thoroughfare in the world to be lighted in this way, on January 28, 1807.

When Winsor and his supporters tried to get a Bill through the House of Commons to authorise the formation of a company, it was opposed very vigorously by Boulton and Watt, who by this time seem to have had some glimmering of the possible value of the gas process, and by their efforts the Bill was thrown out. Subsequently, however, it became law on June 9, 1810.

In one last word I would like to mention also that, in addition to Murdoch and Lebon, another man who ought fitly to be regarded as a pioneer of the gas process is Samuel Clegg, who was very luckily appointed chief engineer of the first gas company in London, and who had been a mechanic under Murdoch. This Clegg was also an extraordinary man, and it may interest your readers to know that with regard to the present "Caracristi" low-temperature carbonisation plant now being erected by the Ford Company in the United States, in 1825 Samuel Clegg designed and worked a retort on almost identical lines, that is a travelling cast-iron plate continuous carbonising apparatus, although he used a fire underneath and not a bath of molten lead.

I may say that I gave some time ago a paper on the history of the gas process before the Newcomen Society for the Study of Historical Engineering, which name may perhaps not be familiar to the average chemist, and this paper will be available in the "Transactions" of that Society in the near future.—I am, Sir, etc., DAVID BROWNLIE

BETTON'S BRITISH OIL

Sir,—In the article by Dr. W. Forbes-Leslie (May 23), on "The Oil Shales of Somerset," mention is made of the extraction of oil for medicinal purposes in 1761. It would be of interest to know if this refers to "Betton's British Oil," which was stated to have been obtained by the distillation of the bituminous sandstone of Pitchford, in Shropshire. The oil was sold by a family named Boyce in Shrewsbury, about eighty years ago, and was much esteemed as a cure for sprains and rheumatism. The pitch well does not now appear to be productive, but it was the means of making a considerable fortune for the inventor of the medicament. The introduction of the shale-oil industry is somewhere stated to have its origin in the refining, in 1847, by James Young, of the crude petroleum of Alfreton, in Derbyshire, to which attention had been called by Lord Plyfair.

Perhaps some further information, or verification of the points mentioned, though only of historic interest, may be forthcoming.—I am, Sir, etc.,

H. A. AUDEN

Whitehedge Road,
Garston
June 2, 1924

VIEWS FROM DOWN UNDER

Sir,—"Caret Law" from Paisley has a go at you on March 14, this number has just come to hand here, and as I had already made some similar reflections about chemists and lawyers, I am encouraged to raise my voice from Down Under, so look out.

Personally I do think that the canny lawyers have got the advantage in respect to the organisation of their profession, but then they never do anything new, they always look up all manner of musty precedents before they begin, and above all things, they never get in a hurry. What on earth would a lawyer do if he were asked unceremoniously for a decision on some important matter and was expected to answer in, say, a couple of hours, yet how many chemists are expected to provide accurate data for the buying department based on analysis which can only be given by a good expert in the time named; what on earth does a lawyer ever produce except long series involving n to n+m multiples of 6/8 where n and m are any large numbers.

With such a narrow outlook how relatively easy it was for them to have so organised and arranged their profession as to be able to secure easy times for themselves and good remuneration. Then again, their work brings them all the time into close contact with the human side of affairs, they are not called upon to live half their lives in a mental world remote from all the commonplace affairs around them, the lawyer is always commonplace, it is his job. The creative chemist spends more than half his life thinking of things as remote as possible from this; even fellow chemists wrapped in their own particular affairs and difficulties, only similar in their remoteness from the commonplace find it difficult to understand each other. I noticed in one of the journals the other day (I am not sure if it were yours) that some chemist had been "slinging off" as we say out here, about the absence of chemists on boards of guardians, town councils and the like, how in the world does he suppose that a man is to spend all his day, for instance, on the synthesis of $aa\beta\beta$ dextro-laevomethylethyl anthraquinonal sulphonamide, and then go and spend his evening listening to complaints from Jones about the failure of the drains in X street, or to plumb the depths of subtlety involved when Mrs. Y, with n+1 children and a husband who "drinks" applies for new blankets for the winter.

But seriously I am really delighted with the effort Mr. Woolcock is making to found Chemistry House, and I shall have little sympathy with you if you grumble when our energetic president (where does he get it all from) demands that YOU, from the height of your Olympic Chair, should see that the lower world gets moving in the matter. Tell Mr. Woolcock that I wish him every conceivable success, and that I look forward on my return (if ever I do return) to an invitation from him to a nice cosy, comfortable, well-furnished place (in Chemistry House) somewhere near a "bar" where a good whiskey and soda will make us both feel very human and of the world, and perhaps even delightfully commonplace.—I am, Yours, etc.,

HARRY WILLIAMS

Arlington Mills,
Botany, N.S.W.
April 25, 1924

PERSONAL AND OTHER ITEMS

The following names are included in the official list of His Majesty's Birthday Honours:—Baronet: Alexander Grant, chairman of Messrs. McVitie and Price. Knights: W. Galloway, D.Sc., A. Smith Woodward, D.Sc., F.R.S., lately Keeper of Geology in the British Museum. Order of Merit: Prof. Sir C. S. Sherrington, President of the Royal Society. G.B.E.: Sir Josiah Stamp, K.B.E., D.Sc. C.B.E.: Dr. E. P. Cathcart, M.D., F.R.S., professor of chemical physiology, Glasgow University; R. Townsend, chief superintendent of ordnance factories, War Office. Imperial Service Order: W. J. Bean, curator of the Royal Botanic Gardens, Kew. Congratulations are to be offered to Sir Alexander Grant, who has been a member of the Society of Chemical Industry since 1905.

The Council of the Royal Society of Arts has unanimously resolved to confer the Albert Medal for 1924 on the Prince of Wales, in recognition of services rendered to arts, manufactures and commerce as president of the British Empire Exhibition, and by his visits to the Dominions and India.

It is reported by *The Times* that an assistant chemist formerly employed by Bayer's dye works at Leverkusen, has been sentenced at Würzburg to six months' imprisonment for the betrayal of industrial secrets. He was convicted of having sold a number of dye secrets, of which he had illegally obtained possession, to persons in Great Britain and the United States.

At the sale of the late Sir J. Dewar's library, 37 guineas was paid for the Journal of the Chemical Society, 1871–1923 and that Society's Annual Reports on the Progress of Pure Chemistry, 1904—1922.

From Paris the death is announced of Monsieur Emile Deutsch de la Meurthe, a director of the petroleum refinery bearing the same name.

Mr. J. G. A. Roberts, J.P., vice-chairman of Boake, Roberts and Co., Ltd., manufacturing chemists, Stratford, E., who died on February 10, has left £110,128, with net personalty, £108,059.

Dr. N. Comber has been elected to the chair of agricultural chemistry in the University of Leeds, which has been vacant since the retirement of Prof. C. Crowther, now Principal of the Harper Adams Agricultural College.

The University of Melbourne has decided to confer the title of emeritus professor of chemistry upon Sir David Masson in recognition of his services to the University.

The death of Commendatore Ersilio Baroni deprives the Associazione Chimica Industriale di Torini of one of its founders. Comm. Baroni was the president of the Società Italiana Esplosivi e Munizioni.

Dr. H. O Hofman, professor of metallurgy in the Massachusetts Institute of Technology, and author of valuable treatises on metallurgy, died recently in Cambridge, Mass.

Dr. K. G. Jonas, of the Breslau Technical *Hochschule*, has been appointed to succeed Prof. E. Heuser in the chair of cellulose chemistry, in the Darmstadt Technical *Hochschule*.

At the annual meeting of the Institution of Civil Engineers, the following officers were elected:—President, Mr. Basil Mott. Vice-Presidents, Sir W. H. Ellis, Mr. F. Palmer, Sir Archibald Denny, and Mr. E. F. Crosbie Trench. Members of Council: Mr. H. N. Allott, Mr. A. A. Biggs, Sir J. Cadman, Sir D. Clerk, Colonel R. E. B. Crompton, Mr. H. A. Cutler, Mr. W. W. Grierson, Sir R. A. Hadfield, Sir B. H. Henderson, Mr. E. P. Hill, Mr. G. W. Humphreys, Sir C. R. S. Kirkpatrick, Sir M. Macdonald, M.P., Mr. J. MacGlashan, Mr. J. P. Maxwell, Sir H. P. Maybury, Sir J. Monash, Mr. G. T. Nicholson, Mr. J. B. Porter, Sir R. A. S. Redmayne, Sir H. Reid, Capt. M. H. P. R. Sankey, Sir J. F. C. Snell, Mr. W. A. P. Tait, Mr. J. D. Watson, and Sir A. F. Yarrow.

The Sugar Industry in France

The total production of sugar from October 1, 1923, to April 15, 1924, was 436,894,166 kg., whilst the output of glucose was 17,077,295 kg.

The Physics of Textile Fibres

One of the Sessions of the Empire Textile Conference which will be held at the British Empire Exhibition, Wembley, during Whitsun week, will be devoted to a General Discussion on "Physical and Physico-chemical Problems relating to Textile Fibres." This Discussion is being arranged jointly by the Faraday Society and the Textile Institute, and it will be held on Wednesday, June 11, from 2.30 to 6.30 p.m., in Conference Hall No. 4. The Introductory Address will be given by Dr. W. Lawrence Balls, F.R.S., and the programme of 12 papers includes contributions from all the leading laboratories in Great Britain and Ireland engaged in textile research. Full particulars may be obtained from the Secretary of the Faraday Society, 10, Essex Street, London, W.C. 2, or from the Secretary of the Textile Institute, St. Mary's Parsonage, Manchester.

REVIEWS

CHEMISTRY IN THE TWENTIETH CENTURY

AN ACCOUNT OF THE ACHIEVEMENT, AND THE PRESENT STATE OF KNOWLEDGE IN CHEMICAL SCIENCE. London: Ernest Benn, 1924. Pp. viii + 281. Price 15s.

The volume under review, which contains twenty-four essays written by experts in each selected branch of chemical science, has been compiled under the guidance of a Committee representing the Scientific Societies. Among these learned associations the Society of Chemical Industry has made important contributions, for the preface is furnished by its President-designate, Mr. W. J. U. Woolcock, and the introduction, a comprehensive survey of current chemical activities, is the work of the President, Dr. E. F. Armstrong.

This treatise should be considered in conjunction with the scientific exhibits in the Chemical Hall of the British Empire Exhibition (1924), to which collections it is to be regarded as a supplementary handbook. The articles may be divided broadly into two classes: monographs dealing with the fundamental principles of chemistry, and those describing the manifold applications of the science.

A philosophical dissertation by Prof. Irvine Masson on "The Rôle of Chemistry in Physical Science," which might with equal appropriateness have been termed the rôle of physics in chemical science, indicates clearly and in homely language the manner in which the two kindred sciences are becoming more and more intertwined.

In "The Structure of the Atom" Dr. Andrade discusses the nuclear atom, atomic number, isotopes and atomic energy. Chemists who are busy with less fundamental problems will find in this essay a useful synopsis illustrated by striking diagrams. It may, however, be remarked that there are still two modes of considering chemical elements, just as there are two ways of looking at a flock of sheep. In the latter instance there is the brutally detached view of the butcher who regards sheep in the aggregate merely as portable forms of mutton from which he can by the aid of appropriate physical instruments cleave off cutlets and other oddments. But there is another and more sympathetic viewpoint, that of the shepherd who distinguishes clearly between one member of his flock and another, and to whom these individuals represent personalities with distinctive traits and peculiar idiosyncracies. Only a butcher physicist, gazing without a sigh on the ruin he has made, by a bombardment with α-particles, could conclude (p. 50) that "nitrogen which has lost a proton becomes carbon; aluminium which has lost a proton becomes magnesium and so on." The perplexed and saddened chemist—the shepherd of his elementary flock—is tempted to ask whether, indeed, carbon has ever been definitely identified among the sub-atomic mangled remains of nitrogen, and if so how could this astounding transmutation have been accomplished merely by the loss of one proton?

The confused description of the formation of ammonium chloride (p. 55), in which the hydrogen of hydrogen chloride, "negatively charged" after losing an electron to chlorine, becomes attracted by the nitrogen kernel, is not going to help chemical students to a clear comprehension of complex salts, still less will it convert to a belief in the modern electrical theory of combination those writers (pp. 107 and 174) who retain the opinion that oxonium and carbonium salts contain quadrivalent oxygen.

These comments may serve to emphasize what in the reviewer's opinion is the singular omission from this volume of an article dealing specifically with valency and chemical combination from the chemist's viewpoint. Many papers have appeared recently in *Chemistry and Industry* on these topics, and similar discussions have taken place at the Chemical Society. Yet in this popular treatise on modern chemistry there is no adequate treatment of the contributions by British chemists to these fundamental problems.

The visitor to the Scientific Section of the British Empire Exhibition will notice on several stalls models illustrating the structure of chemical molecules, yet apart from incidental references under crystallography and under the chemistry of carbon compounds there is no simple description of the fascinating subject of general stereochemistry. A great opportunity has thereby been lost of bringing home to the intelligent enquirer the outstanding fact that, although molecules are infinitely small in comparison with ordinary every-day dimensions, nevertheless the component atoms of these tiny particles behave as if they had a definite arrangement in space. This intimate knowledge of the chemical molecule, first discovered in the case of carbon derivatives, is ever growing and becoming applicable to the compounds of other elements, and to this extension of science British chemists have contributed notably, as will be seen by a survey of the scientific exhibits.

Mr. Barker's article on "Crystallography," written in characteristically lucid style, is based on his highly educational exhibit which includes Wollaston's reflecting goniometer representing a crucial step in the development of crystallographic science, and the identical crystal of potassium ferrocyanide employed by Moseley in his classical research on atomic numbers. The interest attaching to this excellent monograph is greatly increased by the inclusion of a judicious selection of typical diagrams and plates.

Sir William Bragg contributes a short essay on X-ray analysis and deals with the structure of such representative substances as rock salt, fluorspar, calcite, diamond, graphite, naphthalene and anthracene.

The article by Dr. Travers on the discovery of the rare gases of the atmosphere should serve as a tonic for those doubting souls who are dubious about the principle of "science for science's sake." Although only thirty years have passed since the discovery of argon, three of the five inert gases have found application in the arts and manufactures. Concerning the other two the author ends with a

note of interrogation, "Yet who shall say that industry may not some day find use for them?" A similar question may be asked concerning all the other less common elements.

The chemistry of carbon compounds, the story in simple terms of organic chemistry, deals with structure and with the unsaturated state of carbon derivatives. Reference is made to the functions of oxygen and nitrogen in organic compounds and to tautomerism and the chemistry of benzene. The ultimate aim of organic chemistry is revealed in the statement that "the whole subject of biochemistry, which is the chemistry of life, will form but a part of organic chemistry." This anticipation is followed by a gleam of cheery optimism which one may readily associate with the author, Prof J. F. Thorpe:—"When this is the case the causes of our bodily ills will be as clear as the structure of indigo; and their removal as easy as a test tube reaction. The treatment of disease will be as sure and as certain as the neutralisation of ammonia by sulphuric acid." Whatever may be the result of this simplification on the panel system, "'tis a consummation devoutly to be wished."

"Milestones in Organic Chemistry," the title of Prof Armstrong's reminiscences from 1865 to the present, serve to define modern stages in the development of the organic branch in chemistry.

The article on the chemistry of colloids deals not only with the fundamental study of the colloidal condition but also with practical applications in the arts. Highly informative résumés are contributed on catalysis, fats and oils, sugar and carbohydrates, cellulose and synthesis in the terpene series. The essay on colour in nature ranges from chlorophyll to blue skies, blue eyes and the iridescence of feathers. The article on coal tar colours, written at a few hours' notice by Mr. Bearder, refers *inter alia* to the effect of the great war on the home production of synthetic dyes and intermediates. Essays on the biological aspect of chemistry deal with the alkaloids, the nitrogenous constituents of the living cell, biochemistry and fermentation and chemistry in agriculture. The applications of chemistry in metallurgy and ceramics are outlined in authoritative contributions on alloys and on pottery and refractories. Flame, fuel and explosion furnish a popular theme dealing with modern researches on coal, the nature of flame and hydrocarbon combustion.

It is apparently a far cry from explosives to the chemistry of photography, yet it will be noticed in the two concluding articles that each of these applications of chemical science has made important progress as the result of the great war. There is only too great a tendency nowadays to forget the enormous impetus which this regrettable catastrophe has had on the development of British chemistry in the colleges and universities and also in the arts and manufactures. This treatise, together with the splendid exhibits of the Chemical Hall in the Palace of Industry, will be a timely reminder of what the British Empire owes to chemical science.

G. T. M.

CHEMICAL INDUSTRY PAMPHLETS

CHEMISTS AND THEIR WORK. By Stephen Miall. THE QUEST FOR COLOUR. By A. T. de Mouilpied, B.Sc. (Lond.), M.Sc. (Vict.), Ph.D., F.I.C. WOOD PRODUCTS. By T. W. Jones, B.Sc. FINE CHEMICALS. By T. W. Jones, B.Sc. THE HEAVY CHEMICAL INDUSTRY. By Rex Furness. CHEMISTRY IN THE MANUFACTURE OF PIGMENTS, PAINTS AND VARNISHES. By C. A. Klein, M.Sc. London: Ernest Benn, Ltd. 1924. Price 6d. each net.

These are the first six of a series of "Chemical Industry Pamphlets" which are being issued under the ægis of the Society of Chemical Industry and the Association of British Chemical Manufacturers. They are most fascinating tracts written in an engaging manner understandable by all, and possess high literary merit. Though prepared with a view to propaganda the interest which most of them arouse is in no way tainted by this fact. The enlightenment of the public as to the nature and extent of the services rendered to the community by chemists is a task which many people think needs to be undertaken, but one which is so little to the taste of men of science that few care to undertake it. The self-sacrificing authors of these booklets have acquitted themselves remarkably well.

In most cases the subject is dealt with historically, and a clear picture is given in simple yet accurate language of what applied chemistry achieves in providing the comforts of modern life, its security, enjoyment, freedom, and leisure. They are not "dry-as-dust" publications, but by a truly eloquent appeal to the imagination rank as first-class literary productions. This is especially true of "The Quest for Colour," by Dr. de Mouilpied, "The Heavy Chemical Industry," by Mr. Rex Furness, and "Chemists and their Work," by Dr. Miall, the Editor of this *Journal*, whose ability to arouse the interest of the non-chemist in matters generally regarded as only of interest to chemists is already well known.

It is to be hoped that the pamphlets will reach the wide circle of readers for whom they are intended, and that all members of the Society of Chemical Industry will do their utmost to assist in fulfilling this purpose.

F. H. CARR

THE CHEMISTS' YEAR BOOK, 1924. By Dr. F. W. ATACK, assisted by L. WHINYATES; American data in collaboration with F. M. TURNER. Pp. 1147. Manchester: Sherratt and Hughes, 1924. Price 21s.

The Chemists' Year Book has undergone many changes in its ninth edition. Instead of appearing in two volumes, the *Year Book* now is issued in one volume, at no sacrifice of its handiness, and the work has been subjected to considerable revision and amplification, including the addition of a quantity of American data. New sections have been added on Water Analysis (by S. E. Melling), on Essential Oils (by T. H. Durrans), and on Spirits (by F. Robinson), whilst considerable changes have

been made in the sections on the General Properties of Inorganic Compounds, Physico-Chemical Constants, Leather Analysis, Brewing Materials, Dairy Products (which now includes both British and United States methods of examination), Analysis of Tobacco, and Agricultural Chemistry, the last-named section being contributed by Sir John Russell and H. J. Page. It is impossible to make a detailed examination of a work that covers so much ground, but a comparison with previous editions shows that the editors are fully aware of their responsibilities in keeping the work up to date and in striving to improve it. Suggestions given in reviews of former editions have been adopted in some cases, but the section on neutralisation methods still awaits revision and a few minor points require attention. A work that has reached its ninth edition requires no further blessing, and it will suffice to say that the improvement evident in each subsequent edition is most satisfactory evidence of the desire for perfection.

(1) Light and Colour. By R. A. Houstoun, M.A., Ph.D., D.Sc. Pp. xi+179. London: Longmans, Green and Co., 1923. Price 7s. 6d.

(2) A Treatise on Light. By R. A. Houstoun, M.A., Ph.D., D.Sc. Pp. xi+486. New edition, revised and enlarged. London: Longmans, Green and Co., 1924. Price 12s. 6d.

(1) Any work that presents the facts of science in a really sound, non-technical way is to be welcomed, and Dr. Houstoun's work on "Light and Colour" deserves a warm welcome. Dr. Houstoun treats mainly of aspects of light and colour that make a general appeal, not only to the amateur or the public, but to the growing number of those who are concerned with subjects such as photography, the medical and social effects of light and lighting, colour matching and many more.

After discussing the spectrum, the nature of light, and invisible rays in the first three chapters, an interesting account is given of spectroscopic investigation and the structure of the atom and of stars. Chapters follow on the primary colours, colour blindness, colour photography, the light of the future, photochemistry, phototherapy, and the psychology of colour. The writing is easy and thoroughly interesting, and the book can be safely recommended. In a future edition it would be well to give the equivalent of μ in the metric system on page 26.

(2) In this treatise Dr. Houstoun caters for those who possess a good knowledge of elementary physics and mathematics, but he has wisely dealt with the full scope of the subject and has included the results of important recent work. The work is divided into four parts, devoted to geometrical optics, physical optics, spectroscopy and photometry, and mathematical theory. All but one of the chapters conclude with a number of examples, and the book will be of value to all students of physics and chemistry, as well as to chemists who wish to refresh their knowledge of optical principles. A commendable feature of both works is their moderate price.

COMPANY NEWS

SAN SEBASTIAN NITRATE CO., LTD.

The directors report that the net profit in 1923 was £8418, compared with £807 in 1922. The balance available, with £8055 brought in, is £16,473, and a dividend of 5 per cent., less tax, is proposed (against nil), £5000 is applied in reduction of property account, and £5948 is carried forward (against £8055 brought in). Last August the directors acquired for £15,000 the "Enriqueta" grounds immediately adjoining the company's old properties. The manufacture of nitrate was resumed on May 1, 1923, and has been carried on steadily and economically. Profit has been taken in the accounts on 66,570 metric quintals of nitrate produced by the company itself, and on 22,876 metric quintals representing sales to other producers.

NORTH BRITISH RUBBER CO., LTD.

The report states that after transferring £50,000 from general reserve and allocating £16,020 for depreciation on buildings, machinery, plant, etc., and £43,150 as provision for loss on foreign exchange and stocks of canvas, motor tyres, and paying the dividends for the year on the first and second Preference shares, there remains £24,092 to be carried forward.

SAN PATRICIO NITRATE CO., LTD.

The report for 1923 shows a profit, after providing stoppage expenses and the usual administrative charges, of £4443, which increases the profit and loss credit to £10,025. A dividend of 6d. per share, free of tax, is recommended, absorbing £2500. The report states that the oficina remains closed, and that the quota to June 30 next has been sold. For 1922 there was a loss of £1348, but a dividend of 6d. per share, free of tax, was paid.

BURMAH OIL CO., LTD.

According to the report, all fields expenditure has been charged direct to revenue, and the profit for the year, after deducting income-tax, contribution to employees' provident fund, directors' fees, etc., and writing off £333,237 for depreciation, is £2,203,896. There has been transferred to insurance reserve £20,000, and to general reserve £200,000, leaving £1,983,896. To this is added £201,095 brought forward, making £2,184,991. Preference dividends absorb £257,500, and the interim dividend of 2s. per share, free of tax, on the ordinary shares, £515,119, leaving £1,412,372. The directors recommend a final dividend on the ordinary shares of 4s. per share free of tax, leaving £382,133 to be carried forward, subject to corporation profits tax.

SCOTTISH OILS, LTD.

The report for the year ended March last states that the balance at credit of profit and loss account, including £31,465 brought forward and after providing for depreciation, is £103,528. The directors recommend a dividend of $3\frac{1}{2}$ per cent., less tax, on the participating preference shares, requiring £80,379. The carry forward is £23,149.

ALIANZA CO.

The net profit for 1923 is £183,536, after providing £45,903 for exhaustion of raw material, and £5450 for depreciation of plant (in 1922 the net profit was £152,759, and £22,850 was allowed for exhaustion of raw material, and £10,947 for depreciation. With £447,090 brought forward, a total of £630,626 is available, and allowing for a carry forward of £130,626, it is proposed to pay a final dividend of 20 per cent., making a total distribution of 100 per cent. (40 per cent. in 1922). The company has acquired from the Liverpool Nitrate Co. the plant, grounds, and stocks of Oficina Buenaventura for £120,000. The local board has declared a further interim dividend of 20 per cent., and this dividend, which will be payable on June 20, is intended to take the place of the above proposed dividend at the same rate, and no further dividend will accordingly be recommended at the meeting on July 23.

FULLERS' EARTH UNION

The accounts to March 31 show a net profit of £14,963, and it is proposed to pay a dividend of 15 per cent., to place £5256 to reserve (which becomes £29,750) and to carry forward £762.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Smoke Abatement

In a written answer addressed to Mr. Lorimer, Mr. Wheatley said that the Government hoped to introduce a Bill dealing with the subject of smoke abatement, at an early date.—(May 28.)

Dyestuffs

Replying to Mr. Baker, Mr. Lunn gave the following statement showing the quantities of intermediate coal-tar products used in the manufacture of dyes, and finished coal-tar dyestuffs registered as imported into the United Kingdom during the year ended December 31, 1923:—

	Intermediate coal-tar products used in the manufacture of dyes (including aniline, oil and salt, and phenylglycine)	Finished coal-tar dyestuffs.		
		Alizarine	Synthetic indigo	Other sorts
	Cwt.	Cwt.	Cwt.	Cwt.

United States	—	174	—	—
Total ..	60,813	283,027	23,889	155

The latter statement shows the quantities of dyes and dyestuffs obtained from coal tar, registered as imported into the United Kingdom from the several countries of consignment, during the year ended December 31, 1913.—(May 30.)

REPORT

Report on the Economic and Commercial Conditions in Switzerland, to February, 1924. By O. A. Scott, Secretary in Charge of Commercial Affairs, Berne. Department of Overseas Trade. Pp. 88. H.M. Stationery Office, 1924. Price 2s. 6d.

The year 1923 must again be considered as one of transition, but conditions are better than they were when the last report was drawn up (*cf. Chem. and Ind.*, 1923, 795). Imports during the first nine months of 1923 amounted to 1536 million frs., compared with 1356 mill. frs. the previous year, whilst exports were valued at 1270 mill. frs. against 1318 mill. frs. Foodstuffs and textiles are the principal items of import. Coal is the next in importance, 1,349,456 t. being imported in the period mentioned above, or 85 per cent. of the pre-war quantity. Increased building activity has had the effect of increasing imports of timber, and in the middle of the year of metals also, both manufactured and semi-manufactured. Imports of chemicals show an increase, the following being some of the items in 1923:—Colophany, 2293 t.; soft pitch, 3698 t.; caustic potash and soda, 6152 t.; sulphate of alumina etc., 2957 t.; tanning substances, 2632 t.; aniline, 1563 t.; linseed oil, 3569 t.; machinery oil, 9829 t.

Exports appear to have taken a favourable turn. The aluminium industry continues to develop, and exports in the period under review were valued at 14·7 mill. frs. The machine industry showed a slight improvement over 1922 conditions; the future of the industry is considered to depend on the increased output of high-grade products rather than on cheap mass-production. The situation in the chemical industry is satisfactory; the restrictions on importation into Britain have reduced this trade, but not stopped it, whilst German competition is less keen. Notwithstanding foreign competition it was found possible to maintain the production of dyestuffs; exports of aniline dyes in 1923 amounted to 3166 t., and of indigo to 2828 t.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Business is maintained at a satisfactory level with a fair export business and very steady values.

Acetic Acid, 40% tech. .. £23 10s. per ton.

Acid Hydrochloric .. .. 3s. 6d.—6s. per carboy d/d., according to purity, strength and locality.

Acid Nitric 80° Tw. .. £21 10s.—£27 per ton makers' works according to district and quality.

Acid Sulphuric .. .. Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.

Ammonia Alkali .. .. £6 15s. per ton, f.o.r. Special terms for contracts.

Bleaching Powder .. Spot £11 d/d.; Contract £10 d/d. 4 ton lots.

Bisulphite of Lime .. £7 per ton, packages extra.

Borax, Commercial—

Crystal .. .. .. £25 per ton.

Powder .. .. £26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)

Calcium Chloride .. £5 17s. 6d. per ton d/d.

Potash Caustic .. .. £30—£33 per ton.

Potass. Bichromate .. 5¾d. per lb.

Potass. Chlorate .. .. 3d.—4d. per lb.

Salammoniac .. .. £32 per ton d/d.

Salt Cake .. .. £3 10s. per ton d/d.

Soda Caustic, solid .. Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.

Soda Crystals .. .. £5 5s.—£5 10s. per ton ex railway depots or ports.

Sod. Acetate 97/98% .. £24 per ton.

Sod. Bicarbonate .. £10 10s. per ton carr. paid.

Sod. Bichromate .. .. 4½d. per lb.

Sod. Bisulphite Powder 60/62% .. .. .. £18—£19 per ton according to quantity, f.o.b., 1-cwt. iron drums included.

Sod. Chlorate .. .. 3d. per lb.

Sod. Nitrate refd. 96% .. £13 5s.—£13 10s. per ton ex Liverpool. Nominal.

Sod. Nitrite, 100% basis £27 per ton d/d.

Sod. Sulphide conc. 60/65 About £14 10s. per ton. d/d

Sod. Sulphide cryst. .. £9 per ton d/d.

Sod. Sulphite, Pea Cryst. £15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—

Golden .. .. .. 5¾d.—1s. 4d. per lb., according to quality.

Crimson .. .. 1s. 3d.—1s. 6d. per lb., according to quality.

Arsenic Sulphide, Yellow 1s. 11d. per lb.

Barytes .. .. .. £3 10s. to £6 15s. per ton, according to quality.

Cadmium Sulphide .. 3s. 9d. per lb.

Carbon Bisulphide .. £24—£26 per ton according to quantity.

Carbon Black .. .. 6¼d.—6¾d. per lb. Market firmer.

Carbon Tetrachloride .. £56 per ton, drums free.

Chromium Oxide, green .. 1s. 3d. per lb.

Indiarubber Substitutes, White and Dark — 4¾d.—6½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.

Lamp Black .. .. 43s. 6d. per cwt., barrels free.

Lead Hyposulphite .. 7½d. per lb.

Lithopone, 30% .. .. £22 10s. per ton.

Mineral Rubber "Rubpron" .. .. .. £15 10s. per ton f.o.r. London.

Sulphur .. .. .. £10—£12 per ton, according to quality.

Sulphur Chloride .. 3d. per lb., carboys extra.

Thiocarbanilide .. .. 2s. 9d. per lb.

Vermilion, pale or deep .. 5s. 1d. per lb. Much dearer, following rise in quicksilver.

Zinc Sulphide .. .. 7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—

Brown .. .. .. £14 10s. per ton d/d. Demand active.

Grey .. .. .. £19—£20 per ton.

Liquor .. .. .. 9d. per gall. 32° Tw.

Charcoal .. .. .. £7 5s.—£9 per ton, according to grade and locality. Market steady.

Iron Liquor .. .. 1s. 7d. per gall. 32° Tw.
1s. 2d. „ „ 24° Tw.

Red Liquor .. .. 10d.—1s. per gall. 14/15° Tw.

Wood Creosote .. .. 2s. 7d. per gall. Unrefined.

Wood Naphtha—

Miscible .. .. 5s.—5s. 3d. per gall. 60% O.P. market stiffer.

Solvent .. .. 5s. 6d.—6s. per gall. 40% O.P. Fairly good demand but little offering.

Wood Tar .. .. £5 per ton.

Brown Sugar of Lead .. £49 per ton.

TAR PRODUCTS

Acid Carbolic—

Crystals .. .. 6½d.—7d. per lb. Demand quiet.

Crude 60's .. .. 1s. 9d.—1s. 10d. per gall. Market flat. Only odd lots being offered.

Acid Cresylic, 97/99 .. 2s. 1d.—2s. 2d. per gall. Demand still good. Market firm.

Pale 95% .. .. 1s. 10d.—1s. 11d. per gall. Steady demand.

Dark .. .. .. 1s. 8d.—1s. 11d. per gall. Steady business.

Anthracene Paste 40% .. 4d. per unit per cwt. Nominal price. No business.

Anthracene Oil—

Strained .. .. 9½d. per gall. Very quiet.

Unstrained .. .. 8½d.—9d. per gall.

Benzole—

Crude 65's .. .. 10½d.—1s. per gall. ex works in tank wagons.

Standard Motor .. 1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.

Pure .. .. 1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.

Toluole—90% .. .. 1s. 5½d. per gall.

Pure .. .. 1s. 10d.—2s. per gall.

Xylol coml. .. .. 2s. 3d. per gall.

Pure .. .. 3s. 3d. per gall.

Creosote—	
Cresylic 20/24% ..	9d.—9½d. per gall. Few inquiries.
Middle Oil ..	7½d.—9d. per gall. according to grade and district. Demand not so strong.
Heavy	
Standard Specification	
Naphtha—	
Solvent 90/160 ..	1s. 4d.—1s. 5d. Market steady.
Solvent 90/190 ..	1s. 2d.—1s. 3d. Fair business, passing.
Naphthalene Crude—	
Drained Creosote Salts	£6—£6 10s. Demand falling off.
Whizzed or hot pressed	£9—£12 per ton. Little business.
Naphthalene—	
Crystals and Flaked ..	£17—£18 per ton.
Pitch, medium soft ..	52s. 6d.—57s. 6d. per ton. Market steadier. Few inquiries for forward delivery. Very little business for prompt.
Pyridine—90/160 ..	21s. 6d.—22s. per gall. Demand well maintained.
Heavy ..	12s.—12s. 6d. More business passing.

Deliveries are still only required in very small quantities owing to the desire of consumers to keep stocks down.

INTERMEDIATES AND DYES

Business in dyestuffs has improved slightly during the week.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% ..	1s. 6d. per lb.
Acid H.	4s. 4d. per lb. 100% basis d/d.
Acid Naphthionic ..	2s. 4d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech. ..	1s. 2d.—1s. 3d. per lb. Steady
Acid Sulphanilic ..	10d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	7¾d.—8½d. per lb. naked at works.
Aniline Salts	7¾d.—9d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95% ..	1s. 3d. per lb.
p Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o Cresol 19/31° C. ..	4¾d. per lb. Demand moderate.
m Cresol 98/100% ..	2s. 1d.—2s. 3d. per lb. Demand moderate.
p Cresol 32/34° C. ..	2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline	3s. per lb.
Dichloraniline S. Acid ..	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£75 per ton.
Diethylaniline	5s. per lb. d/d., packages extra, returnable.
Dimethylaniline	2s. 4d. per lb. d/d. Drums extra.
Dinitrobenzene	9d. per lb. naked at works.
Dinitrochlorbenzol ..	£84 10s. per ton d/d.
Dinitrotoluene—48/50°C.	8d.—9d. per lb. naked at works.
66/68°C.	1s. 2d. per lb. naked at works.
Diphenylamine	3s. per lb. d/d.
Monochlorbenzol	£63 per ton.
β Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine ..	1s. 4½d. per lb. d/d.
β-Naphthylamine ..	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p Nitraniline	2s. 4d. per lb. d/d.
Nitrobenzene	5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol ..	2s. per lb. 100% basis d/d.
Nitronaphthalene ..	11¾d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine ..	4s. 2d. per lb. d/d.
p-Phenylene Diamine ..	10s. 4d. per lb. 100% basis d/d.
R. Salt	2s. 5d. per lb. 100% basis d/d.
Sodium Naphthionate ..	2s. 6d. per lb. 100% basis d/d.
o-Toluidine	8½d. per lb.
p-Toluidine	3s. 6d. per lb. naked at works.
m-Toluylene Diamine ..	4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P. ..	£48 per ton.
Acid, Acetyl Salicylic ..	3s. 3d.—3s. 5d. per lb. In good demand.
Acid, Benzoic B.P. ..	3s. 9d. per lb. Larger supplies available.
Acid, Boric B.P. ..	Cryst. £54 per ton, Powder £58 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	19s.—21s. per lb.
Acid, Citric	1s. 6½d. per lb., less 5% for ton lots. Market extremely firm. Upward tendency.
Acid, Gallic	3s. per lb. for pure crystal. Market very steady.
Acid, Pyrogallic, Cryst. ..	7s. per lb. for 1 cwt. lots. Market firm; increasing demand.
Acid, Salicylic	Prices quoted from 2s. per lb. down to 1s. 9d. for ton lots. Market weak.
Acid, Tannic B.P. ..	3s. per lb. Market quiet.
Acid, Tartaric	1s. 1½d. per lb. less 5%. Much firmer with more demand. Upward tendency.
Amidol	9s. per lb. d/d.
Acetanilide	2s. 3d. per lb. for quantity. Stocks are small.
Amidopyrin	13s. 6d. per lb. Neglected. Stocks low.
Ammon. Benzoate ..	3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate ..	12s. per oz. for English make.
Barbitone	15s. 6d. per lb. Quiet market.
Benzonaphthol	5s. 6d. per lb. Small inquiry.
Bismuth Salts	A steady market. Prices according to quantity:
Bismuth Carbonate ..	12s. 9d.—14s. 9d. per lb.
„ Citrate	11s. 4d.—13s. 4d. „
„ Salicylate ..	10s. 2d.—12s. 2d. „
„ Subnitrate ..	10s. 9d.—12s. 9d. „
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides	Fluctuating market. Continental prices decidedly firmer.
Potassium	11d. per lb.
Sodium	1s. „
Ammonium	1s. 1d. per lb.
Calcium Lactate	Demand active. Good English make can be had from 1s. 7d. to 2s. 6d. per lb.
Chloral Hydrate	3s. 10d. per lb., duty paid. Advanced. Higher prices are quoted from the Continent.
Chloroform	2s. per lb. for cwt. lots. Market more active. Makers busy.
Creosote Carbonate ..	6s. 6d. per lb. Little demand.
Formaldehyde	£57 per ton, *ex* works. English make.
Glycerophosphates—	Fair business passing
Calcium, soluble and citrate free	7s. per lb.
Iron	8s. 9d. per lb.
Magnesium	9s. per. lb

Potassium, 50% .. 3s. 6d. ,,
Sodium, 50% .. .. 2s. 6d. ,,
Guaiacol Carbonate .. 12s. per lb. for cwt. lots. Supplies not plentiful.
Hexamine .. .. 3s. 9d. per lb. for English make. Market dull.
Homatropine Hydrobromide .. .. .. 30s. per oz.
Hydroquinone .. .. 4s. 3d. per lb. in cwt. lots. Foreign make.
Hypophosphites—
Calcium . .. 3s. 6d. per lb., for 28 lb. lots.
Potassium . .. 4s. 1d. per lb.
Sodium.. . 4s. ,,
Iron Ammon Citrate B.P. 2s. 1d.—2s. 5d. per lb., according to quantity. Advanced by 2d. per lb.
Magnesium Carbonate— ..
Light Commercial £36 per ton net.
Magnesium Oxide—
Light Commercial .. £75 per ton, less 2½%.
Heavy Commercial .. £26 per ton, less 2½%.
Heavy Pure .. .. 2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—
A.B.R. recryst. B.P. . 60s. per lb. Weaker.
Synthetic .. .. 26s.—35s. per lb., according to quantity. English make. Steady demand.
Mercurials .. .. Market firm.
Red oxide .. .. 5s. 3d.—5s. 4d. per lb.
Corrosive sublimate .. 3s. 6d.—3s. 7d. ,,
White precip. .. .. 4s. 7d.—4s. 8d. ,,
Calomel .. .. 3s. 11d.—4s. ,,
Methyl Salicylate .. 2s. 3d.—2s. 9d. per lb. for carboys. A slightly better market.
Metol .. .. .. 11s. per lb. British make.
Paraformaldehyde .. 3s. 6d. per lb. Better inquiry.
Paraldehyde .. .. 1s. 4d.—1s. 6d. per lb. in free bottles and cases. Better demand.
Phenacetin . . 6s. per lb.
Phenazone .. .. 7s. 3d. per lb. for cwt. lots. Quiet.
Phenolphthalein .. .. 6s. 9d.—7s. 3d. per lb. In more plentiful supply.
Potass. Bitartrate—
99/100% (Cream of Tartar) .. .. 88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate .. .. 1s. 10d.—2s. 2d. per lb. Dearer.
Potass. Iodide .. .. 16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Metabisulphite .. 7½d. per lb., 1-cwt. kegs included.
Potass. Permanganate—
B.P. Crystal .. .. 8¾d.—9d. per lb. carriage paid.
Commercial .. .. 8d.—8¼d. per lb. carriage paid.
Quinine Sulphate .. 2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin .. .. .. 5s. 6d. per lb.
Saccharin . .. .. 63s. per lb., in 50-lb. lots
Salol . 3s. 6d. per lb. Very quiet.
Silver proteinate .. 9s. 6d. per lb.
Sod. Benzoate, B.P. .. 2s. 6d. per lb. In steady demand for good qualities.
Sod. Citrate, B.P.C., 1923 2s.—2s. 2d. per lb., according to quantity. Much firmer in common with other citrates. Prices advanced by 2d. per lb.
Sod. Hyposulphite—
Photographic .. .. £14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst. 37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside .. 16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt) .. 77s. 6d.—81s. 6d. per cwt., according to quantity. Market quiet
Sod. Salicylate .. .. Market easier. Powder 2s. 3d.—2s. 6d. per lb. Crystal at 2s. 5d.—2s. 8d. per lb. Flake 2s. 9d.—2s. 10d. per lb.
Sod. Sulphide—
Pure recryst. .. .. 10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous £27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Thymol .. .. .. 15s. per lb. for good white crystal from ajowan seed. Very firm and scarce.

PERFUMERY CHEMICALS

Acetophenone .. .. 12s. 6d. per lb.
Aubepine .. .. .. 14s. 6d. per lb.
Amyl Acetate .. .. 2s. 9d. ,,
Amyl Butyrate . .. 6s. 9d. .. Cheaper.
Amyl Salicylate .. .. 3s. 3d. ,,
Anethol (M.P. 21/22° C.) 4s. 6d. ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol 3s. 3d. ,,
Benzyl Alcohol free from Chlorine .. .. 3s. 3d. ,,
Benzaldehyde free from Chlorine .. .. 3s. 6d. ,,
Benzyl Benzoate .. 3s. 6d. ,,
Cinnamic Aldehyde Natural.. .. .. 15s. 6d. ,,
Coumarin .. .. 20s. ,,
Citronellol .. .. 16s. ,,
Citral .. .. .. 10s. ,,
Ethyl Cinnamate .. 15s. ,,
Ethyl Phthalate .. .. 3s. 3d ,,
Eugenol .. .. .. 11s. ,,
Geraniol (Palmarosa) .. 35s. ,,
Geraniol .. .. .. 11s.—18s. 6d. per lb.
Heliotropine .. .. 6s. 6d. per lb.
Iso Eugenol .. .. 15s. 9d. ,,
Linalol ex Bois de Rose.. 28s. 6d. ,,
Linalyl Acetate .. .. 28s. 6d. ,,
Methyl Anthranilate .. 9s. 6d. ,,
Methyl Benzoate .. 6s. ,,
Musk Ambrette .. .. 48s. 6d. ,,
Musk Xylol .. .. 16s. 6d. ,,
Nerolin .. .. .. 4s. ,,
Phenyl Ethyl Acetate .. 12s. 6d. ,,
Phenyl Ethyl Alcohol .. 16s. ,,
Rhodinol .. .. .. 57s. 6d. ,,
Safrol .. .. .. 1s 10d. ,,
Terpineol .. .. .. 2s. 9d. ,,
Vanillin .. .. .. 25s. 3d.—26s. 6d. per lb.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A. .. .. .. 15s. 6d. per lb.
Anise Oil .. .. .. 3s. per lb.
Bergamot Oil .. .. 18s. 6d. per lb.
Bourbon Geranium Oil .. 36s. 6d ,, Advanced.
Camphor Oil .. .. 75s. per cwt.
Cananga Oil, Java .. 10s. 6d. per lb.
Cinnamon Oil, Leaf .. 6½d. per oz.
Cassia Oil, 80/85% .. 9s. 3d. per lb.
Citronella Oil—
Java 85/90% .. .. 6s. per lb. Again dearer.
Ceylon .. .. .. 3s. 9d. per lb.

Clove Oil ..	.. 7s. 6d. ,,
Eucalyptus Oil 70/75% ..	2s. 2d. ,,
Lavender Oil—	
French 38/40% Esters	.. 27s. 6d. per lb.
Lemon Oil ..	.. 3s. 2d. per lb.
Lemongrass Oil ..	.. 3d. per oz.
Orange Oil, Sweet	.. 13s. 9d. per lb.
Otto of Rose Oil—	
Bulgarian ..	.. 27s. 6d. per oz.
Anatolian ..	.. 23s. 6d. per oz.
Palma Rosa Oil ..	.. 19s. per lb.
Peppermint Oil—	
Wayne County	.. 21s. 6d. per lb.
Japanese ..	.. 16s. 3d. per lb.
Petitgrain Oil ..	.. 10s. per lb.
Sandal Wood Oil—	
Mysore	.. 26s. 6d. per lb.
Australian ..	.. 21s. per lb.

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before July 28th; they are on sale at 1s each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on June 12th.

I.—Applications

Anderson. Installation for separation of liquids. 12,277. May 19. (Fr., 7.6.23.)

Brandwood. Filtering apparatus. 12,561, 12,562. May 22.

Carpenter. Separation of liquids from solids. 12,826. May 24. (U.S., 25.7.23.)

Hoganas Billesholms Aktiebolag. Expelling gas from solid bodies. 12,565. May 22. (Sweden, 15.6.23.)

Metallbank und Metallurgische Ges. Treating gases with granular adsorption agents. 12,258. May 19. (Ger., 13.6.23.)

Nyrop. Drying liquids yielding residues. 12,745. May 23.

Partridge and Thompson. Separation of solid particles from flue gases. 12,591. May 22.

Perkeo Akt.-Ges. fur Schaumloschverfahren. Production of foam for fire extinguishing. 12,410. May 20. (Ger., 9.6.23.)

Soc. Chimique des Usines du Rhône. Catalysts. 12,295. May 19. (Fr., 26.7.23.)

Thermal Syndicate Ltd. Apparatus for condensing vapours. 12,580. May 22.

Wilton. Mechanical furnaces. 12,713. May 23.

I.—Complete Specifications Accepted

1591 and 1982 (1923). Rigby. Drying processes. (215,812.)

10,338 (1923). Gill (Sharples Specialty Co.). Preventing formation of emulsions. (215,929.)

17,147 (1923). Lodge-Cottrell, Ltd. (Metallbank und Metallurgische Ges.) *See* II.

27,611 (1923). Marchant, and Marchant Bros., Ltd. Roller grinding-mills. (216,048.)

9115 (1924). Farberei u. Appretur Ges. vorm. Clavel und Lindenmeyer. Centrifugal drying apparatus. (214,279.)

II.—Applications

Appleby and Bentley. Gas-producers. 12,606. May 22.

Badische Anilin- und Soda-Fabrik. Manufacture of liquid fuels. 12,697. May 23. (Ger., 14.1.24.)

Beale, Pitkethly, and Smith. Apparatus for cracking mineral oils. 12,620. May 22.

Berg- und Huttenwerks Ges., and Gobiet. Process for improving coke. 12,407, 12,408. May 20. (Czechoslovakia, 17.3.24.)

Coke and Maxted. Catalytic oxidation of paraffin hydrocarbons. 12,654. May 23.

Ges. fur Chemische Produktion, and Clemm. Manufacture of decolorising charcoal. 12,268. May 19. (Ger., 5.7.23.)

Hurrell. 12,446. *See* IX.

Küng. Generation of heating flames. 12,696. May 23. (Switz., 1.6.23.)

Prudhomme. Manufacture of carburetting liquids similar to petrol. 12,689. May 23.

Rude. Carbonisation of solid fuel. 12,681. May 23.

Testrup. Distillation of shales etc. 12,368. May 22.

II.—Complete Specifications Accepted

25,790 (1922). Neath. Manufacture of gas from coal or from coal and oil. (215,496.)

4632 and 10,555 (1923). Stenning, and Minerals Separation, Ltd. Concentration of coal. (215,811.)

10,338 (1923). Gill (Sharples Specialty Co.). *See* I.

17,147 (1923). Lodge-Cottrell, Ltd. (Metallbank und Metallurgische Ges.). Cleaning gases, more particularly producer gases. (216,001.)

19,826 (1923). Humphreys and Glasgow (Rusby). Gasification of bituminous coal etc. (216,021.)

19,975 (1923). Humphreys and Glasgow (Dashiell). Manufacture of gas. (216,022.)

23,952 (1923). Koppers. Coke ovens. (204,345.)

8896 and 8897 (1924). Algem. Norit Maatsch., and Sauer. Reactivating decolorising carbon. (213,939 and 213,940.)

IV.—Applications

Chemische Fabrik Griesheim-Elektron. Manufacture of azo dyestuffs. 12,626. May 22. (Ger., 22.5.23.)

Farbwerke vorm. Meister, Lucius, u. Bruning. Manufacture of vat dyestuffs. 12,625. May 22. (Ger., 21.8.23.)

Imray (Soc. of Chemical Industry in Basle). Manufacture of indigoid dyestuffs. 12,284. May 19.

Johnson (Badische Anilin- u. Soda Fabr.). Manufacture of black vat dyestuffs. 12,795. May 24.

Menke. 12,717. *See* XX.

V.—Applications

Amber Size & Chemical Co. Ltd. 12,736. *See* VII.

Bloxam (Chemische Fabrik Griesheim-Elektron). 12,283. *See* XIII.

Know Mill Printing Co., Ltd., Mort, and Weeks. Treatment of cellulosic materials, fibres, etc. 12,330. May 20.

Lilienfeld. Manufacture of cellulose compounds. 12,627, 12,628, and 12,629. May 22. (Austria, 4.4.24.)

Stevenson. Manufacture of artificial silk from viscose. 12,797. May 24.

V.—Complete Specifications Accepted

4332 (1923). Dreyfus. Manufacture of pressed or moulded articles from compositions containing cellulose derivatives. (215,823.)

4896 (1923). Mordioni. Manufacture of viscose silk. (215,851.)

11,248 (1923). Radolin. *See* XIX.

14,675 (1923). Van Overstraeten. Purification of wool washing waters. (215,985.)

VI.—Applications

Bedford. Mordanting and dyeing wool. 12,550. May 22.

Carstairs, and Martin and Co. Process of waterproofing fabrics. 12,779. May 24.

Day. Dyeing-machine. 12,670. May 23.

Lepine. Desulphurising, bleaching, washing, and dyeing fibres etc. 12,223. May 19.

Morton Sundour Febrics, Ltd., and Harris. Dyeing. 12,733. May 23.

VI.—Complete Specification Accepted

5231 (1923). Calico Printers' Association, Ltd., and Roberts. Production of pattern effects on fabrics. (215,860.)

VII.—Applications

Amber Size and Chemical Co., Ltd. Production of aluminium compounds for paper-making etc. 12,736. May 23. (Ger., 2.7.23.)

British and Foreign Lime and Power Corporation, Ltd., and Reid. Burning of limestone etc. 12,622. May 22.

Chemical Engineering and Wilton's Patent Furnace Co., Ltd., and Wilton. Manufacture of sulphate of ammonia. 12,508. May 21.

Hackford. 12,291. *See* IX.
Höganäs-Billesholms Aktiebolag. Production of aluminium oxide. 12,566. May 22. (Sweden, 15.6.23.)
Robinson. Production of oxides of sulphur. 12,730. May 23.
Russell. Production of colloidal sulphur. 12,707. May 23.

VII.—Complete Specifications Accepted

1301 and 24,711 (1923). Frank. Producing alumina and glass-making salts. (215,810.)
1673 (1923). Laporte, Ltd., and Alcock. Manufacture of phosphoric acid.

VIII.—Applications

Babcock and Wilcox Co. Refractory product. 12,299. May 19. (U.S., 25.5.23.)
Babcock and Wilcox Co. Kaolin refractory. 12,300. May 19. (U.S., 25.5.23.)
Mead. Coating metal with enamel, glass, etc. 12,394. May 20.

VIII.—Complete Specifications Accepted

1301 and 24,711 (1923). Frank. *See* VII.
28,996 (1923). Huard. Manufacture of glass. (207,195.)

IX.—Applications

British and Foreign Lime and Power Corporation, Ltd. 12,622. *See* VII.
Francois and Williams. Wood-preserving compound. 12,286. May 19.
Hackford. Manufacture of lime, mortar, or cement. 12,291. May 19.
Hurrell. Emulsions of bituminous substances. 12,446. May 21.

X.—Applications

Indiana Steel and Wire Co. Process of zinc coating of iron etc. articles. 12,387. May 20. (U.S., 10.12.23.)
Mandowsky. Manufacture of sulphur-containing casting compounds. 12,619. May 22. (Ger., 13.6.23.)
Mead. 12,394. *See* VIII.
O'Donovan. Muffle furnaces. 12,380. May 20. (Union of S. Africa, 25.1.24.)

X.—Complete Specifications Accepted

31,685 (1922). Edwards and Durant. Treatment of oxidised ores or other oxidised compounds of copper and zinc. (215,802.)
4286 (1923). Eisen- und Stahlwerk Hoesch. Heating and smelting furnaces. (193,401.)
4690 (1923). Beasley, Edser, and Minerals Separation, Ltd. Briquetting of ores. (215,815.)
5716 (1923). Ashcroft. *See* XI.
7253 (1923). Marks (American Manganese Steel Co.). Melting manganese steel. (215,895.)
7281 (1923). Passalacqua. Tin-plating metals, particularly aluminium and its alloys. (194,729.)
7970 (1923). Dunford and Elliott, Ltd., and Pehrson. Manufacture of zinc.
11,235 (1923). Rushen (Krupp). Magnetic separation of materials. (215,935.)
13,519 (1923). Junghans. Plating metals. (204,303.)
19,622 (1923). Saklatwalla. Ferrous alloys. (202,971.)

XI.—Application

Soc. Italiana E. Breda. Electric furnaces. 12,514. May 21. (Italy, 28.5.23.)

XI.—Complete Specifications Accepted

5716 (1923). Ashcroft. Apparatus for electrolysing fused salts. (215,872.)
208 (1924). Metropolitan-Vickers Electrical Co. Electrical insulating Coatings. (209,421.)

XIII.—Applications

Bloxam (Chemische Fabrik Griesheim-Elektron). Manufacture of coloured cellulose-ester varnishes. 12,283. May 19.
Gehrke and Martin. Manufacture of white paint etc. 12,263. May 19.
Preiss. Coating material, and manufacture thereof. 12,260. May 19.
Ueter. Manufacture of lacquers, paints, etc. 12,802. May 24. (Ger., 28.5.23.)

XIII.—Complete Specification Accepted

4336 (1923). Hynson and Stephens. Manufacture of a basis composition for printers' and like inks. (215,824.)

XIV.—Complete Specification Accepted

29,191 (1922). Dunlop Rubber Co., and Twiss. Vulcanisation of india-rubber. (215,796.)

XV.—Application

Carmichael and Ockleston. Tanning. 12,324. May 20.

XVII.—Application

Alves da Cunha, Ltd. Sugar refining apparatus. 12,692. May 23. (Portugal, 10.7.23.)

XVIII.—Complete Specification Accepted

16,564 (1923). Klein. Manufacture of pressed yeast. (203,300.)

XIX.—Applications

Bloxam (Akt.-Ges. für Anilin-Fabrikation). Disinfecting seed grain. 12,716. May 23.
Slate. Refrigeration and preservation of perishable products. 12,711. May 23.

XIX.—Complete Specifications Accepted

11,248 (1923). Radolin. Cereal husks etc. (215,936.)
14,675 (1923). Van Overstraeten. *See* V.

XX.—Applications

Blagden, and Howards and Sons. Making synthetic menthol. 12,520. May 21.
Coke and Maxted. 12,654. *See* II.
Johnson (Badische Anilin- und Soda-Fabrik). Manufacture of organic compounds. 12,794. May 24.
Menke. Production of nitrated organic compounds. 12,747. May 23.

XX.—Complete Specification Accepted

18,853 (1923). Deutschmann and Kotzenberg. Antitoxic serums. (216,014.)

XXI.—Application

Sury. Photographic pigmentary printing paper. 12,363. May 20. (Belgium, 30.5.23.)

XXIII.—Applications

Mono Ges. Analysing test gases. 12,377. May 20. (Ger., 31.5.23.)
Owens. Instrument for estimating suspended matter in gases etc. 12,512. May 21.

XXIII.—Complete Specification Accepted

877 (1923). Laese. Apparatus for determining the specific gravity of gases. (191,738.)

PUBLICATIONS RECEIVED

TEXTBOOK OF CELLULOSE CHEMISTRY. By Emil Heuser. Translated from the second German edition by C. J. West and G. J. Esselen, Jr. Pp. xi+212. London: McGraw-Hill Publishing Co., Ltd., 1924. Price 12s. 6d.

ORE DRESSING, PRINCIPLES AND PRACTICE. By T. Simons. Pp. xvii+292. London: McGraw-Hill Publishing Co., Ltd., 1924. Price 17s. 6d.

SOIL MANAGEMENT. By Firman E. Bear. Pp. vi+268. London: Chapman and Hall, Ltd., 1924. Price 10s.

THE TEXTILE FIBRES. THEIR PHYSICAL, MICROSCOPICAL, AND CHEMICAL PROPERTIES. By J. M. Matthews, Ph.D. Fourth edition, revised and enlarged. Pp. xviii+1053. London: Chapman and Hall, 1924. Price 50s.

JOURNAL of THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 43 NEW SERIES LONDON, JUNE 13, 1924 No. 24

EDITORIAL

A CORRESPONDENT proposes to add a new charm to life by publishing a volume of chemical verse. We ourselves have often speculated on the possibility of doing this, but ours was a mere dream when we were "careless and unthoughtful lying hearing soft winds about us flying." Our correspondent is putting his ideas into execution, and we are well content to wait until his volume appears. In this journal several verses, some of them we can hardly call poetry, have already appeared, and we think that if discreet enquiries are made in Cambridge, in the chemical laboratory will be found one at least who, while engaged in filtration or titration, builds the lofty rhyme, "for he on honey-dew hath fed and drunk the milk of Paradise." Chaucer deals with alchemy, Lucretius with atomic theories, Dr. Bridges in "Wintry Delights" has a turn at chemistry, Mr. Ellis in "Samson Adami" has a stanza on Kékulé's benzene formula, and there are probably many chemists who at some time or other have been lifted out of their usual level into the sublime. "So some strange thoughts transcend our wonted themes, and into glory peep." We envy our correspondent his task, we picture him as Matthew Arnold described another scholar "nursing the project in unclouded joy, and every doubt long blown by time away." Sir Frederick Pollock turned the Leading Cases into verse, and very good verse too, and he appealed to his muse for a terrible punishment on all critics: "Deadly and swift thy revenge on such carping and cavilling creatures, grievous and grim their reward at thine hand, and the sword of thy vengeance: All the Reports at large we will take and versify likewise." We look forward to the book with eager anticipation; it will be the sort of book described in the "Ars Poetica" as bringing profits to the booksellers, crossing the briny ocean and giving eternal renown to the famous man who strings these pearls together. We trust many of our readers will call attention to some of the gems of purest ray serene lying hid in Victorian treatises. For our part we intend to furbish up some early verses of our own composition—"our joy in them was past expression, but that was thirty years ago," and if you include us in the list of lyric poets we shall be exalted to the skies in our sublimity: *Quodsi me lyricis vatibus inseres, Sublimi feriam sidera vertice.* Bring us quick the Golden Treasury and a flagon:—

"Oh, for a draught of vintage! that hath been
Cool'd a long age in the deep delved earth,
Tasting of Flora and the country green,
Dance and Provençal song and sunburnt mirth."

* * *

Everyone who is accustomed to consult scientific literature must be well aware how often authors neglect to go back to the original sources for authoritative statements. A publishes a certain opinion, B copies it, then C copies B, D copies C, omitting the name of A, and, long before the alphabet ends and our readers' patience is exhausted, the opinion, with probably a little embroidery, has become that snare, an "accepted fact." The history of mankind bears its full burden of "accepted facts"; indeed, this extremely human process of transmission is the source of much of the charm of history. But there is, or should be, no excuse for obscurities in the history of fairly recent chemical processes. Recently we drew attention to obscurities in the history of the gas process, and a correspondent, who had evidently been at great pains to authenticate his facts, showed, conclusively it seemed, that William Murdock was the true pioneer of the industrial production of gas. None of the accounts of

early experimenters in gas lighting, however, has mentioned George Dixon, of Cockfield. According to a letter published in *The Times*, Mr. W. Dixon possesses indisputable evidence that the original inventor was his namesake, George, who possessed collieries near Durham, "near one of which he had a small manufactory to produce coal tar, which was first used in shipbuilding at Sunderland, and where he first made inflammable coal gas about 1760." About that time Dixon had lit his house with coal gas and he was thinking of using it for lighting his collieries. But during the distillation of a ton of coal with the object of finding the yield of tar, an ill-advised experiment with a candle led to the not unnatural conclusion that his project of lighting collieries and rooms with gas lights was very dangerous. The facts of the case are to be found in the "General View of the Agriculture of the County of Durham," published by John Baily, a nephew of Dixon, in 1810. We are glad to add this information to that already published, but we are becoming very sceptical. Did Faraday really discover benzene in 1825?

* * *

Our readers must have had many and varied occupations during the past week-end. Some probably joined in the light fandango at Brighton or Blackpool, others may have gone to Wembley to see the spirit-stirring bullfight, or to consider the fascinations of the Chemical Section in the Palace of Industry, and others, wise men, may have stopped at home in cushioned ease, considering, merely considering, how much needs to be done in the garden. No one, however, had sufficient energy to reproach us for omitting to notice the centenary of the birth of Alexander William Williamson, on May 1. We remember reading a poem which ran: "Here early parts accomplished Jones sublimes, and science blends with Asia's lofty rhymes. Harmonious Jones! who in his splendid strains sings Camdeo's sports, on Agra's flowery plains." Who was Harmonious Jones we do not know and we fear that to many students of chemistry the name of Williamson is equally unenlightening. Yet Williamson's ideas had incontestibly an influence on the development of modern chemical theory. He was the first to explain the process of etherification and, in 1850, he put forward a view which, in modified form, is of fundamental importance in the modern theory of ionic dissociation the idea of intermolecular exchange and atomic motion. If only for his active advocacy of the atomic theory at a time when chemists were reluctant to accept atoms as physical units, he deserves our warm remembrance. And, during his presidency of the Chemical Society in 1870 he brought about an innovation of the greatest importance; he initiated the practice of issuing abstracts of papers on chemical subjects, an innovation which has been adopted as standard practice by practically all scientific societies, with far reaching effects on the propagation of scientific knowledge. No further title to our gratitude is needed.

SOME FURTHER REMARKS ON OPTICAL ROTATION-DISPERSION

By T. S. PATTERSON

Mr. Hunter, in his article in *Chemistry and Industry* of May 23, devotes some attention to views which I have published elsewhere on the subject of Optical Activity, and I welcome his article partly because I think it most desirable that these questions should receive adequate discussion, so that we may perhaps reach some opinions in common; and also because—I say it without intending any malice—I feel that another article or two like Mr. Hunter's would suffice firmly to establish my point of view.

It is a little difficult to deal with Mr. Hunter's article, however, because of his lack of precision in certain important respects. He will clearly have none of my views, and yet he seems to disclaim allegiance to the views of Lowry. Nevertheless, he is of opinion that "dynamic isomerism furnishes the best, in fact, the only explanation of the phenomena of rotation-dispersion." He adopts therefore the rather paradoxical position of agreeing "in the main," with my criticisms of Lowry's views, and yet continuing to hold the views which my criticisms undermine. It is fortunate that Mr. Hunter explicitly mentions the fact of this agreement with me, for so skilfully does he dissemble his approval that I should certainly have been left, otherwise, in some doubt on the subject. He also indulges in a certain exuberance of language leading him into some serious dialectic difficulties which will be referred to further on.

Mr. Hunter discusses first what he calls my "sine curve" theory, but which I should prefer to call a "periodic curve" theory; and he finds it to be unsatisfactory. I need only say that here, to a large extent, Mr. Hunter merely beats the air, as he ascribes to me views that, as shown even in the passages he quotes, I expressly disclaimed. I mentioned a sine curve merely as an example of a periodic curve, and I clearly stated in my paper (*J.C.S.*, 1913, **103**, 156) that I considered the experimental data insufficient to allow of an attempt to express them mathematically. At the same time if I were minded to make such an attempt I should not be deterred by any of the difficulties which trouble Mr. Hunter, especially by the consideration that the period of the sine curve which is "very nearly linear for a temperature range of nearly 200° C.," "must be very large in order to accommodate a linear curve of this great temperature range," an objection which he says, "alone robs Prof. Patterson's suggestion of most of its claim to be regarded as a valuable contribution to our knowledge of the subject." That the period of a graph should be large is not necessarily in contradiction to my views. But I agree to a large extent with Mr. Hunter when he says "the fact that an expression can be made to fit a given set of figures is no guarantee that it is the correct equation to apply—no theoretical deductions whatever can be drawn from its use," and I presume that he intends this remark to apply also to the Drude expressions, to which he seems to be so firmly attached.

After stating, fairly enough, my suggestion in regard to the periodicity of temperature-rotation curves, Mr. Hunter decides that it "has very little to recommend it"; that it "fails to co-ordinate the observed experimental facts"; that "it requires a good deal of faith for its acceptance." Periodicity, it seems, is very difficult to observe in my results, "no trace of it is to be found in the results obtained by other investigators," a statement which, considering the fact that I have developed my views by making extensive use of the results of Frankland, Pickard, Armstrong, Walden, Grossmann and others, giving full references, seems to indicate in Mr. Hunter's attitude a slight trace of injustice. It is true that it is difficult, within the range of temperature accessible to us, to observe a sufficient length of a temperature-rotation curve, completely to show its periodicity. But when, as in the case of ethyl tartrate, the T—R curve rises rapidly from a fairly high negative value, passes through the zero of rotation, reaches a maximum and begins to descend again; when, in certain temperature-rotation curves, notably those of the benzoyl tartrates examined by Frankland and Wharton*, a minimum and a point of inflection both occur, the assumption that this is part of a periodic curve is completely in accordance with the facts as far as they are known.

Mr Hunter's next point is quite an important one. He says that the practice of grafting on to the temperature-rotation curve for a homogeneous substance, that for the same substance in some solvent, is entirely indefensible and impracticable, because there is no guarantee that the scales of temperature and rotation respectively are the same in each case. Now the fact, demonstrated in so many cases by the work of Dr Pickard and his collaborators, that the data for the rotation of a homogeneous substance at different temperatures; for various derivatives of that substance also at different temperatures: for that substance or its derivatives in different solvents, and again at different temperatures; all fit, as a general rule, in a most interesting manner on to one characteristic diagram, seems, in my opinion, to show that the grafting, to use Mr. Hunter's word, of temperature curves is quite a legitimate operation, even if, in the meantime, we are not able to deal with it quantitatively. I do not know how Mr. Hunter reconciles his disapproval of my procedure with the fact of the characteristic diagram.

Mr Hunter then cites *d.-sec.* octyl formate (*J.C.S.*, 1923, **123**, 1) and acetate (*J.C.S.*, 1914, **105**, 861) to show "that closely-related compounds do not always have similar temperature-rotation curves," from which it would appear that Mr. Hunter's opinion has undergone a considerable change since the more recent of these papers was published. On page 8 we find it stated that "the temperature-rotation curves of *d.* β octyl formate are similar to those of the acetate, etc., in that its lævo-rotation increases with rise of temperature whilst in the case of the acetate, etc., the rotation decreases with rise of temperature, that is to say, in all cases rise of temperature produces a change in rotatory power in the same sense." It is clear also from the data quoted in these two papers that, as Mr. Hunter says, the T—R curves for the octyl formate would intersect at a low temperature, whilst those of the acetate do actually intersect at a temperature of about 160°; and that those of the homologues would, in all probability, intersect at higher and higher temperatures. The data for all of these substances fall upon the very interesting characteristic diagram shown on p. 845; the point of intersection of the T—R curves for two given colours of light of these different substances—the rational zero—is the same or very nearly the same for all. Therefore, the case quoted by Mr. Hunter as an objection to my view is, in fact, entirely in agreement with it: there is no contradiction whatever. It appears that there may be found, even in Mr. Hunter's own work, a trace of evidence in favour of my views. It is true that the point of intersection of the T—R curves for the acetate is at a considerably higher temperature than that for the formate, but the sequence in the whole series is consistent; that the temperature interval should be large is, in itself, not a difficulty.

Mr. Hunter describes my suggestion to calculate rotation-dispersion from the rational zero as "merely a piece of geometrical legerdemain, in which the properties of similar triangles are employed to obscure the real scientific issue," stating that I set "out to find a way of calculating dispersion ratios in order to *make* them constant," and remarking that "a constant is useful only when we know what it means," and that "no meaning can be assigned to a dispersion ratio—it is entirely arbitrary."* This seems to raise, amongst others, the question, what is "the real scientific issue"? Is it to investigate by inductive methods the phenomena of nature, or is it to return to the times of the Schoolmen and adapt nature to *a priori* principles? I prefer the former. I do not attempt to *make* dispersion ratios constant: I simply adopt the very significant fact that the difference between the rotations—the dispersion—for two different wave lengths for a given substance and for a series of related substances, over wide limits of temperature, solvent and concentration is directly proportional to the rotation value calculated from a particular point. This is, again, the very obvious lesson of the characteristic diagram: it appears to me to be of the utmost significance, but to Mr. Hunter it apparently has no significance at all. I am afraid we must just leave it at that.

The constancy in the dispersion ratio obtained by use of the rational zero is thus, says, Mr. Hunter, "the rediscovery in a particular form of facts which have been known to scientists for at least two thousand years"—a pronouncement out of which I have not yet been able to extract any meaning.

Mr. Hunter then says that I "cannot be unaware of the fact that there are two kinds of characteristic diagram: those in which all the lines intersect at one point, the zero of rotation: and those in which the lines do not intersect in one point." In one of my papers which Mr. Hunter quotes (*J.C.S.*, 1916, **109**, 1193), I pointed out that if ordinary dispersion

* Full references will be found in J.C.S., 1913, **103**, 145; 1916, **109**, 1139, 1176, 1204; Proc. Roy. Soc. Edin., 1918-19, **39**, 18.

* Surely this is rather an astonishing statement.

coefficients were constant for any substance, it follows that the T—R curves for all the different colours of light must meet on the zero of rotation. I am, however, unaware that any substance has really been found which actually shows quite strictly this behaviour, and it would have been interesting if Mr. Hunter had told us to which substance or substances he was referring.

For substances showing visibly anomalous rotation-dispersion, Mr. Hunter quite correctly points out —as I had pointed out previously (*loc. cit.*, 1191)—that there would be an infinite number of rational zeros, and he seems to find this a difficulty, but he fails to observe that exactly the same difficulty applies to ordinary dispersion coefficients of which, for substances showing anomalous rotation-dispersion, there must also be an infinite number. I can only say that if nature happens to be made in this way we must simply accept the fact. It seems to me to be better to have an infinite number of rational zeros from which the dispersion ratios for the two colours of light concerned are constant over wide ranges of temperature and external circumstances, than to have, as we do have when we calculate them in the ordinary way, an infinite number of dispersion coefficients which show no constancy at all. Mr. Hunter, however, concludes that "the conception of a rational zero must be dismissed as unworthy of further consideration; it was designed for a purpose which has been shown to be unscientific and its adoption leads to a labyrinth of arithmetical computation from which there is no escape." *Et sic transit gloria doctrinae meae!*

Mr. Hunter then passes on to the consideration of my views in regard to the Drude equation, and to dynamic isomerism, as an explanation of anomalous rotation-dispersion. My objection to the Drude expression as interpreted by Lowry is simply that it does not agree with the facts. It is the business of those who adhere to the esoteric cult of the dynamic isomeride* to show that it does. Hitherto they have completely failed. They will not even attempt to discuss the difficulties to which, in my recent article, I referred.

Mr. Hunter says that "to ignore the fact that dynamic isomerism does occur in many cases known to chemists is hardly scientific," with which I quite agree, but I fail to see what bearing it has on my attitude, as I am quite aware of the occurrence of dynamic isomerism, and have indeed concerned myself experimentally with it. But Mr. Hunter adds the statement, "it is known, too, that labile isomerism is sometimes accompanied by complex rotatory dispersion." If this means that the phenomena of labile isomerism and complex rotatory dispersion are associated in these cases as cause and effect, it is a pity that Mr. Hunter has not informed us to which substances he refers. In my article of May 2nd, I pointed out that the phenomenon of dynamic isomerism is quite independent of, and therefore has nothing to do with, the rotatory phenomena in the case of nitrocamphor, which is, I think, the only case that has been definitely discussed in this connexion.

* Dynamicisomeridolatry.

Mr. Hunter simply professes a blind faith in the Drude equation. Although it is, as he says himself "merely an aspiration," he holds that "for the time being we must be content with the knowledge that the modifications (in its constants) we seek must surely be found because the search is being conducted in a logical manner." This is another of Mr. Hunter's indiscretions of language. He cannot *know* that the modifications which he seeks will surely be found and the method of search must be unusual for, "it is true, of course, that the hypotheses are incapable of direct proof, or even, at present, of direct experimental test"; although it seems that Lowry's views—like mine—*have* been "subjected to the acid test of experiment and have been found wanting." Mr. Hunter's views do not constitute even an hypothesis and certainly not a theory; they are merely a fantasy. It would be well if we scientists were to realise more fully the truth of a statement of Karl Pearson, which I have quoted before, that "all science is description and not explanation."* I commend it to Mr. Hunter's attention.

EXPLOSIBILITY

By A. MARSHALL, A.C.G.I.

More than fifty years ago M. Berthelot showed clearly by his researches that all explosives are bodies which are capable of undergoing a rapid reaction with evolution of heat, and subsequent experience has shown the importance of this conception. Even such an insensitive substance as ammonium nitrate can become a dangerous explosive if it be treated too contemptuously, as was revealed by the catastrophes at Kriewald and Oppau. In this case the principal reaction that takes place on detonation is the deep-rooted one:—

$$NH_4NO_3 = 2H_2O + N_2 + \tfrac{1}{2}O_2 + 27\cdot 6 \text{ Cal.}$$

although a number of others are possible and occur when ammonium nitrate is merely heated. It is probable that every compound or mixture that can undergo such an exothermic reaction can be made to explode, provided that there be an adequate evolution of gas or vapour, and the power of the explosive depends principally on the amount of heat evolved in the reactions.

The effect of an explosion depends, however, not only on the power, but also on the velocity of detonation. Various explosives also differ from one another enormously in their sensitiveness to detonation, to heat and to impact and other mechanical impulses. Whereas ammonium nitrate, for instance, requires another powerful explosive and strong confinement to send it off, silver fulminate can be detonated by little more than a touch or by a small spark. Some when ignited, burn rapidly to detonation, whereas

others, such as trinitrotoluene, will generally burn right away without exploding. What causes these differences in behaviour ?

A. Stettbacher lays great stress on the differences to be observed between compounds of the aliphatic and aromatic types. He found that a few grammes of trinitrotoluene detonated in an open crucible or small-arm cartridge case had more effect on the plate underneath than the same amount of nitroglycerin but he ignores the influence of the physical condition and of the density. Liquid nitroglycerin is notoriously difficult to detonate at its maximum velocity, and if it had been used in the form of dynamite it would probably have had a greater effect than the TNT. Or if the latter had been melted and cast into the containing vessel, it would probably have produced but little effect in consequence of the incompleteness of the detonation. Stettbacher further draws attention to the fact that unconfined dinitrobenzene and even dinitronaphthalene are more easily detonated than collodion cotton, although they have much greater deficits of oxygen, and that mono-nitroglycerin cannot be detonated at all, but he overlooks the fact that the heat set free on detonating dinitrobenzene is about the same as with collodion cotton, and that dinitronaphthalene gives off more heat on detonation than mono-nitroglycerin would. This is due to the fact that the heats of formation of the aromatic nitro-compounds are small and those of the nitronaphthalenes are even negative, whereas those of the nitric esters such as the nitroglycerins and nitrocelluloses are high. Nevertheless, it is a fact that the aromatic nitro-compounds are more easily detonated unconfined, although Stettbacher seems to over-emphasize it. He ascribes it to a collapse of the benzene ring on detonation, and there may be some truth in the theory, but speculations of this sort should take into account other types of explosives such as fulminates, azides and ordinary gunpowder.

An explosive has a considerable store of potential energy, and may be likened to a reservoir of water held up by a dam. When a high explosive is detonated it is like the bursting of the dam by an earthquake; the water is suddenly released and sweeps away everything in the valley below, and if there be other reservoirs there, their dams will also be burst by the rush of water. When an explosive is ignited it is like knocking a hole in the dam near the top. If the dam be strong, the water will only flow for a time, and will then cease after it has fallen to the level of the hole. But if the dam be weak it will be eroded rapidly until all the water has escaped, and in an extreme case it may be weakened so much that ultimately it will collapse with results much the same as those caused by the earthquake, except that the water that runs through in earlier stages causes comparatively little damage.

This resembles an explosive burning to detonation. Some sorts, such as fulminate, detonate when less than a milligramme has burned, but of others, such as guncotton or TNT., many kilogrammes or even tons may burn away before there is an explosion.

The slow decomposition of an explosive such as cordite on storage is like water percolating through a porous dam. This also may eventually lead to a catastrophe if the percolation becomes so rapid as to break down the dam.

Such similes must not, of course, be carried too far, but it is hoped that this one will help to afford a clearer conception of the various sorts of explosive. It raises the question: why does the dam sometimes collapse from the base, and sometimes erode from the top ? That is, why does an explosive sometimes detonate and sometimes merely burn or deflagrate ? When it burns, the molecule evidently only breaks down gradually or partially, whereas when it detonates, the molecule is broken up suddenly into its component atoms. The simile therefore continues to hold. On burning, the nitrogen is mostly given off in the form of oxides, and the rest of the molecule oxidises in stages much as a hydrocarbon or alcohol does during combustion. On detonation, on the other hand, the nitrogen is evolved in the elementary form, and the other elements also are converted into very simple compounds, which however, may combine during the cooling of the products to form more complex compounds.

Why do some compounds break down completely and violently when only slightly heated, or struck whereas others which have more available energy break down partially and quietly. The following series of mercury compounds brings out these differences :—

	Heat of Formation Mercury liquid	Heat of Explosion Mercury gas
Mercuric cyanide $Hg(CN)_2$	—55·4	—
Mercuric sulphocyanide $Hg(CNS)_2$	—50·2	—
Mercuric fulminate $Hg(ONC)_2$	—62·9	101·5
Mercurous azide HgN_3	—71·4	57·8
Mercuric oxalate HgC_2O_4	+171·3	3·7

The figures are large Calories per gramme-mol. and are derived from the results given by Berthelot. The fulminate and the azide are, of course, sensitive explosives that can be used to detonate other explosives. The oxalate is only a very mild explosive, as would be expected from the small amount of energy liberated, but it does deflagrate when heated. The cyanide, on the other hand, does not explode under ordinary circumstances in spite of the fact that it is an endothermic compound. When heated it decomposes into mercury and cyanogen with absorption of heat :— $Hg(CN)_2 = Hg + C_2N_2$ 10·3 Cal. The sulphocyanide, also, when ignited undergoes a quiet decomposition, giving off gas and leaving a very voluminous residue. This is our old friend Pharaoh's Serpent.

The following simple endothermic nitrogen compounds are also curious :—

	Heat of Formation.
Ammonium azide $N_4H_4 = H_3N{\cdot}N_3$	—19·0
Nitrogen sulphide N_4S_4	—127·6
Nitrogen chloride NCl_3	—38·5
Cyanogen $(NC)_2$	—73·9

The first three are sensitive explosives, but cyanogen can only be detonated with some difficulty.

We shall probably understand these peculiarities better when we know a good deal more about the structure of the molecules of these substances. As

some of them are very simple crystalline compounds there should be no great difficulty in investigating them by means of the X-ray spectrometer. Such an investigation would throw a light not only on the nature of explosives but also on chemical stability and instability.

Explosives can also be made by mixing together mechanically substances that alone are almost or entirely devoid of explosive properties. It is noteworthy that the addition of sulphur or a sulphide renders a mixture considerably more sensitive. This is the principal function of the sulphur in ordinary gunpowder, for without it the reaction between the saltpetre and the charcoal would be too difficult to initiate. Mixtures containing potassium chlorate are much more sensitive than those containing the nitrate, and this may perhaps be ascribed to the fact that it breaks down with the evolution of heat. Potassium perchlorate, on the other hand, absorbs heat on breaking down and does not produce sensitive mixtures. Ammonium perchlorate, like potassium perchlorate, can be detonated by itself and yields somewhat sensitive mixtures. Ammonium chlorate is so unstable that it cannot be kept.

$$KClO_3 = KCl + 1\tfrac{1}{2}O_2 + 11{\cdot}9 \text{ Cal.}$$
$$KClO_4 = KCl + 2O_2 - 19{\cdot}7 \text{ Cal.}$$
$$NH_4ClO_4 = HCl + 2H_2O + \tfrac{1}{2}N_2 + \tfrac{1}{2}O_2 + 58{\cdot}5 \text{ Cal.}$$

When a mixture contains both a chlorate and sulphur or a sulphide it becomes dangerously sensitive. That of potassium chlorate and sulphide of arsenic (orpiment) is astonishingly so, and has been the cause of numerous accidents, as it is a favourite composition with firework makers in consequence of the ease with which it can be set off and the brilliance of the effects. Only a few days ago I was called on to give expert evidence in a case where an Indian youth had lost both hands through the explosion of a small vaseline bottle filled with this mixture. It has even been known to go off spontaneously. It does not appear possible to account for these facts, unless it be assumed that atoms of sulphur are liable to become attached to chlorate molecules on the surface of the crystal and so form a sort of complex molecules that are highly unstable.

During the war the French used in their aerial bombs a liquid mixture of nitric peroxide and hydrocarbons, and it was found that unless the latter were purified from unsaturated compounds the mixture was too sensitive. This again points to formation of complex molecules of high sensitiveness. With liquid oxygen explosives the experience has been somewhat similar. The American investigators found that when wood pulp or cellulose was used as the oxidisable absorbent, the explosive was too insensitive, and they recommended the addition of crude oil or similar hydrocarbons. The Germans usually employ a mixture of soot and naphthalene when they want a brisant liquid oxygen explosive.

FORTHCOMING EVENTS

June 15 to 21. SOCIÉTÉ DE CHIMIE INDUSTRIELLE. Fourth Congress of Chemical Industry, will be held at Bordeaux.

June 16. ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C. 2, at 4.30 p.m. "The Mineral Wealth of the pre-Cambrian in Canada," by C. V. Corless, M.Sc., LL.D.

June 16. BIOCHEMICAL SOCIETY, Chemical Department, St. Thomas's Hospital, S.E. 1, at 5 p.m. (1) "Millon's Reagent," by W. H. Hurtley. (2) "The Amino Acids of Flesh," by J. L. Rosedale. (3) "Some Conditions Affecting the Action of Arginase," by A. Hunter. (4) "The Transformation in the Calcium Content of the Hen's Egg during Development," by R. H. A. Plimmer and J. Lowndes. (5) "The Action of Nitrous Acid upon Amides and other Amino Compounds." (6) "Hæmolysis of Red Corpuscles," by J. Mellanby and V. J. Woolley. (7) "Further Experiments on the Nutrition of Birds," by R. H. A. Plimmer and J. L. Rosedale.

June 18 and 25. BRITISH EMPIRE EXHIBITION, Conferences on Heredity as the Basis of National and Industrial Efficiency. In Conference Hall No. 3 Wembley.

July 15. THE INSTITUTE OF CHEMISTRY STUDENTS' ASSOCIATION (LONDON). Visit of Chemical Students to Wembley. At 9.45 a.m. an Inaugural Meeting will be held at University College, Gower Street, W.C. 1, at which the President of the Institute, Prof. G. G. Henderson, LL.D., F.R.S., will take the chair. Mr. W. J. U. Woolcock, C.B.E., General Organiser of the Chemical Section of the Exhibition and President-elect of the Society of Chemical Industry, will explain the objects of the exhibits and the special features of interest. Prof. W. P. Wynne, C.B.E., F.R.S., President of the Chemical Society, hopes to support the speaker at the meeting. The cost of the visit, including return ticket to Wembley, entrance to the Exhibition, and ticket for luncheon, will be 5s. Further information can be obtained from Mr. G. S. W. Marlow, 30, Russell Square, London, W.C. 1, and applications should be made not later than June 28.

Sept. 8 to 11. INSTITUTE OF METALS. Annual Autumn Meeting, to be opened at the Institution of Mechanical Engineers, when W. M. Corse, S.B., will deliver the third annual Autumn Lecture. On September 9 the morning will be devoted to reading and discussion of papers, followed by luncheon at the Connaught Rooms, Kingsway, the afternoon to be spent at the British Empire Exhibition. On September 10 further papers will be presented for discussion, the afternoon being devoted to visits to works. A reception will be held in the evening at the National Physical Laboratory, Teddington. A detailed programme will be issued in August.

Sept. 15. BRITISH EMPIRE EXHIBITION. Conferences of Engineering Societies, to be held in Conference Hall No. 1, at 10.30 a.m. Short papers on various Engineering Subjects will be read and discussed. Further information and tickets may be obtained from the Secretary, Society of Engineers, 17, Victoria Street, Westminster, S.W. 1.

THE LOW-TEMPERATURE CARBONISATION OF COAL

There has long been much discussion of the merits and demerits of the process for the carbonisation of coal at low temperatures, but up to the present little progress towards a definite decision seems to have been made. The use of coalite, the smokeless fuel produced by the process, has been slowly extending and the chemical and industrial characteristics of the by-products are beginning to be known. But our heavens are still smoky, our houses sooty, and we still import fuel oil in bulk. It is therefore of much interest to reproduce a letter, which we are able to print by the courtesy of the *Daily Telegraph*, which records a step forward in the history of the process. The letter runs as follows:—

To the Editor of the *Daily Telegraph*.

Sir,—I read on Saturday in the *Daily Telegraph* the inspiring report of what is being done at Alton at Mayor Treloar's Cripples' Hospital, and of the miraculous healing powers of sunshine and light.

To-day I read in the *Nottingham Journal* of the enterprise of the citizens of Nottingham in taking definite steps to make their city the first smokeless town in the country. They are building a low temperature carbonisation plant capable of handling in a scientific manner 1000 tons of coal a day, to render it smokeless and at the same time to produce gas at less cost than hitherto possible, while at the same time the coal oils are to be extracted. These oils are to be converted into motor spirit, Diesel and lubricating oils, which this country now imports. But nothing is of greater importance for the benefit of the community than the abolition of the pall of smoke that hangs over our industrial centres, depressing and fatiguing the inhabitants and rendering them more prone to the diseases of darkness. We must have our full ration of sunshine. It is earnestly to be hoped that other cities will investigate the Nottingham enterprise and follow the lead of this great Midland centre.—Yours faithfully, GEORGE H. ROBERTS

Addison House, Bedford Street, Strand, W.C.
June 3, 1924

It appears that the Nottingham Corporation has arranged to take the gas produced by a low-temperature carbonisation plant which is to be erected in conjunction with the Digby Colliery Company by the Low Temperature Carbonisation Co., Ltd., at the colliery at Gedling. Small, that is, waste coal will be treated for the production of motor spirit, lubricating oil, cheap gas and a perfectly smokeless fuel for industrial or domestic use. It is stated that a plant with a capacity of only 1000 tons a day will, as a beginning, provide Nottingham with roughly 250,000 tons of smokeless fuel a year at a price not higher than that of the best house coal. Such a plant can yield over seven million gallons of crude oil and over one million gallons of motor spirit a year, and the by-products will include not less than 700 million cubic feet of gas of high quality annually. Plans have already been prepared for the new low-temperature carbonisation plant which, it is estimated, will cost between £250,000 and £300,000.

At present we spend between 50 and 60 millions sterling annually on imported oil and each 1000 tons of coal burned in the raw state implies a loss of nearly 20,000 gallons of fuel and other oils, as well as a polluted atmosphere and the waste of large sums on cleaning and redecorating. The installation of low-temperature carbonisation at Nottingham will be watched keenly and success will create a host of imitators. At last there are hopes of real smoke prevention and of real fuel economy.

THE FEDERAL COUNCIL FOR PURE AND APPLIED CHEMISTRY

At the meeting of the Council held on Wednesday, May 14, the following report from the Chemistry House Committee was circulated:—"The Committee is of opinion that the interests of academic, technical and manufacturing chemical science would be well served by the immediate establishment of a Chemistry House on a scale involving an outlay of at least £30,000, but it desires to point out that such an establishment should be regarded as the basis of a larger scheme for providing adequate accommodation for all the organisations representing the corporate interests of academic, technical and manufacturing chemistry. The Committee therefore recommends that the Federal Council should immediately appoint an Executive with instructions to organise and set in motion a scheme for the provision of Chemistry House. (Signed) W. J. Pope, Chairman. 2nd May, 1924." The report was adopted, and it was decided that Messrs. E. F. Armstrong, H. E. Coley, G. G. Henderson, S. Miall, T. Miller-Jones, Sir William Pope, Messrs. W. J. U. Woolcock and W. P. Wynne be the Executive; that they should have power to add to their number and should report progress at suitable intervals to the Federal Council.

Sir William Pope was re-elected President of the Federal Council for a further year.

A Committee, consisting of Sir William Pope, Prof. H. E. Armstrong, Messrs. Bolton, Coley, Drummond and Miall was appointed to draw up a provisional constitution for the Federal Council, and report in the autumn.

Since the Council Meeting preparations have been made for the meeting of the Union Internationale at Copenhagen at the end of June. The following have signified their intention of attending:—Sir William Pope, Prof. C. S. Gibson, Messrs. F. H. Carr, R. L. Collett, Prof. J. C. Drummond, Prof. A. Harden and Mrs. Harden, Dr. Stephen Miall. Others who wish to attend are requested to communicate with Dr. Miall.

A meeting of the Chemistry House Executive has been held recently at which Dr. E. F. Armstrong was appointed Chairman, and other preliminary business transacted.

The next meeting of the Federal Council is fixed for the 11th inst., and a report of the meeting will appear in this journal shortly afterwards.

SOCIETY OF CHEMICAL INDUSTRY

ANNUAL GENERAL MEETING, 1924

PATRON: H.M. THE KING

In accordance with the provisions of by-law 68 notice is hereby given that the Annual General Meeting of the Society of Chemical Industry will be held in the Arts Theatre, The University, Liverpool, on Wednesday, July 9, 1924, at 10.30 a.m.

The following is the official Programme :—

Tuesday, July 8, 9.0 p.m. Informal Reception by the President and the Local Committee at the Midland Adelphi Hotel.

Wednesday, July 9, 10.30 a.m. Annual General Meeting in the Arts Theatre, The University, and Presidential Address, "A Neglected Chapter in Organic Chemistry: The Fats." 2.30 p.m. Visit to White Star Liner, "Cedric," and tea on board, by invitation of the White Star Line. 8.30 p.m. Reception and Dance in the Town Hall, by invitation of the Rt. Hon. The Lord Mayor of Liverpool (Arnold Rushton, Esq).

Thursday, July 10, 10.30 a.m. (hour subject to alteration). Messel Memorial Lecture by the Rt. Hon. Viscount Leverhulme, in the Arts Theatre, and presentation to the Lecturer of the Society's Messel Medal for 1924. 12.30 p.m. (hour subject to alteration). Visit to the Works of Messrs. Joseph Crosfield and Sons, Ltd., Warrington. Luncheon by invitation of the Directors. Inspection of the Works of Messrs. Joseph Crosfield and Sons, Ltd. Cost of travelling, 5s. 7.30 p.m. Annual Dinner, in the Midland Adelphi Hotel. Tickets, exclusive of Wines, 12s. 6d.

Friday, July 11, 10.0 a.m. Business Session in the Physics Lecture Theatre, The University. 1.0 p.m. Luncheon at the Midland Adelphi Hotel, by invitation of the Chairman and Directors of The United Alkali Co., Ltd., followed by visit to Works of The United Alkali Co., Ltd. Cost of travelling, 3s. 6d. 7.30 p.m. Dinner at Port Sunlight, by invitation of the Chairman and Directors of Messrs. Lever Bros., Ltd. Cost of travelling, 2s. 6d.

Saturday, July 12. About 9.30 a.m. (details later). Visit to Lake Vyrnwy. Inspection of the Liverpool Corporation Waterworks (limited to 150). Luncheon and tea, by invitation of the Water Committee of the Corporation of Liverpool. Arrive Liverpool about 9.30 p.m. Cost, dinner on train included, 25s.

Unofficial Excursions. Tickets to be booked in Liverpool at Reception Room :—Chester, River Dee and Eaton Hall; Isle of Man; Llandudno and Beaumaris (sea); Lake District (two days).

Members intending to attend the meeting are asked to send their applications, accompanied by the appropriate remittance, as early as possible to Mr. E. Gabriel Jones, City Laboratories, Mount Pleasant, Liverpool, to whom all inquiries relating to private hospitality, railway travelling and other matters connected with the meeting should be addressed.

A ballot list for the election of Members of Council has been despatched to each member entitled to vote.

J. P. Longstaff,
General Secretary

TORONTO SECTION

The attendance was good during the winter, being as high as 57 at the dinner and 75 at the lecture. The session was a very successful one for the Toronto Section, eight meetings having been held in Toronto and one at Guelph. In December, Mr. R. C. Purdy addressed the Section on "The Vitrification of Clays and Allied Problems in the Ceramic Industry." He particularly stressed the point that one could not predict the temperature at which vitrification would begin, from a chemical analysis of the clay, since this depended upon the character of the minerals present.

Mr. James Vail spoke in January on "The Manufacture, Properties and Uses of Sodium Silicate." At present, solutions of various compositions were on sale, and for each there was a specific use. As an adhesive certain solutions were almost ideal in that they underwent great changes in viscosity upon the subtraction of small amounts of water. This property enabled the manufacturers of certain paper products to operate their machines at much greater velocities when this adhesive was used. The use of sodium silicate in the beating process in paper manufacture greatly aided in the hydrolysis of the fibre.

On February 22, Professor Harcourt, Director of the Department of Chemistry, Ontario Agricultural College, discussed the "Chemistry of Bread and Flour Making." The Canadian miller had at hand a fairly uniform source of raw materials so that he was not faced by a difficult blending problem He did, however, watch his supply of such materials closely since the method of grading wheat would put a slightly shrivelled wheat in a low grade, whereas such a wheat would probably be higher in gluten than a highly graded wheat. Bleaching was not particularly detrimental to flour and enabled one to market a flour from new wheat. The action of such agents was to hasten the ageing of the flour.

A joint meeting with the Canadian Institute of Chemistry on February 29, was addressed by Dr. Banting and Mr. Best, upon the subject "The Application of Chemistry to Chemical Research." Dr. Banting first outlined the general problem of diabetes and its relation to metabolism and then Mr. Best spoke at length upon the role played by chemistry in the development of "Insulin."

Dr. P. E. Klopsteg, who was the speaker at the meeting held on April 4, outlined the fundamental principles underlying the practical determination of the hydrogen ion in an extremely lucid fashion and carried out a number of demonstrations.

The last regular meeting of the session was held on May 2, when the election of officers took place The result of the election was reported elsewhere Mr. A. R. Duff discussed the problem of "Wood Drying." He first gave a summary of the principles underlying the process and then described the various methods employed to obtain as nearly ideal drying as was economically possible. The drying of wood is of vital importance to those engaged in wood distillation since the transportation of useless water presents to them an economic problem.

SOCIETY OF GLASS TECHNOLOGY

During May a party of some twenty members of the Chambre Syndicale des Maîtres de Verreries de France paid a visit to England at the invitation of the Society of Glass Technology, thus returning a visit paid last year to France by members of the British Society. The programme included various visits, and the delegates were guests at the Annual Dinner of the Society in London. The other guests were Dr. E. F. Armstrong, F.R.S. (President of the Society of Chemical Industry), Judge F. E. Bradley, LL.D. (Master of the Glaziers Company), J. Holland, Esq. (President of the Ceramic Society), and Dr. C. Baring Horwood (Master of the Glass Sellers Company).

During the week two meetings were held. The first was held in University College, London, on May 27, and was a joint meeting with the British Society of Master Glass Painters. The President of the latter Society, the Earl of Crawford and Balcarres, was in the chair. Three papers were presented.

Dr. Ethel Mellor, in a paper on "The Decay of Window Glass from the Point of View of Lichenous Growths," gave an interesting account of the acceleration of the decay of glass in ancient stained glass windows by the growth of lichens on the glass. Mr Noel Heaton, B.Sc., discussed "The Decay of Mediæval Stained Glass." The wide variations in resistance to decay found in mediæval stained glass was to be attributed mainly to variations in the composition and physical structure of the glass. Window glass was introduced by the Romans, and their glass was remarkably durable. Analyses of glass of different periods revealed the loss of durability which resulted from a departure from the Roman tradition in mediæval times. The lowest ebb was reached about the end of the fourteenth century, a notable example being the glass of York Minster. Two causes of decay operated simultaneously; surface weathering due to atmospheric action, and pitting due to the structure of the glass. The variations found in stained glass of the same period were due mainly to primitive methods of manufacture. It was characteristic of mediæval glass that the painted portions resisted decay better than the glass itself, which might be attributed to the lead silicate used uniting with the glass to form a more durable composition. The reverse occurred in later times.

The last paper was "The Weathering and Decay of Glass," by Prof. W. E. S. Turner, D.Sc. The nature of the corrosion of glass had been methodically studied by the physical chemist, and the principal causes were now fairly well known. The chief agent of atmospheric action was moisture. All glassware absorbed moisture to an extent dependent on its composition, but partly also on the manner in which it had been treated by the workman. The compositions of stable and unstable glasses were discussed, and it was pointed out that the eventual hollowing out and the furrowing of glass in process of decay were associated with the mechanical treatment which it had received.

The second meeting was held in the Applied Science Department, Sheffield University, on May 29, Col. S. C. Halse, C.M.G., in the chair. The following three papers were presented:—

"Alumino-Silica Minerals in Fired Glass Pots," by W. J. Rees, B.Sc. N. L. Bowen and J. W. Greig, of the Geophysical Laboratory, Washington, U.S.A., had recently investigated the binary system $Al_2O_3 : SiO_2$. They showed that only one compound of alumina and silica was stable at high temperatures; this compound had a composition $3Al_2O_3$, $2SiO_2$. Researches made by the author during the firing of pots, and blocks for glass works, as well as during their use at high temperature, corroborated the results obtained by Bowen and Greig. The proportion of $3Al_2O_3$, $2SiO_2$ was found in refractory materials after firing depended upon the composition of the material, upon the degree and duration of the heating, and upon contact with siliceous matter.

"The Effect of Various Constituents on the Viscosity of Glass," by S. English, M.Sc. To the glass manufacturer, the viscosity of molten glass was perhaps the most important of its properties, as the viscosity and the way in which it varies with alteration of temperature determined whether a glass could be satisfactorily melted, plained and worked. Of the various methods for the determination of the viscosity of liquids the "rotation" method seemed to be the most useful for glass, as it could be used over such a large range of viscosity. In applying this method, the glass was melted from cullet in a standard cylindrical crucible, and an iridioplatinum sheath secured on the end of a porcelain rod was rotated on its own axis in the centre of the crucible. The time required for the sheath to complete one rotation under different loads at various temperatures was determined, and the viscosity was given as a function of the product of the net effective pull and the time of rotation. The apparatus was calibrated by using syrup, the viscosity of which had been previously determined. "The Thermal Endurance of Glass (Part I.)," by V. H. Stott, M.Sc. In spite of its practical importance the theory of the thermal endurance of isotropic bodies had been somewhat neglected. A theory was submitted which, owing to the complexity of the phenomena involved, was necessarily not entirely satisfactory. It was possible to increase the thermal endurance of glass by a suitable thermal treatment, but a general method for effecting this could not be given. Another question was that of finding the shapes of glassware which were most resistant to thermal shock in the limits imposed by usage. From the point of view of thermal endurance, they could choose a glass which suited a given purpose according to its physical properties, but it was most difficult to determine the best process of manufacture for an actual article, or to arrive at a proper method of testing the value of the object made. It was therefore not desirable at present to fix any formal method of testing. Part II., by V. H. Stott, M.Sc., and Edith Irvine, B.Sc. Experiments were made which showed that rupture was generally due to local differences of temperature, rather than to the uniform shrinkage of large surfaces. Since rupture was almost instantaneous, the conductivity of glass could not have great importance.

CORRESPONDENCE

SYNTHETIC ORGANIC COMPOUNDS—A REPLY TO MR. KAY

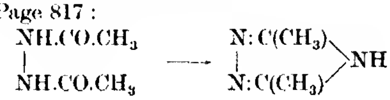
Sir,—I do not propose to deal with all the questions raised by Mr. Wm. E. Kay in your issue of May 2, but I crave your hospitality for a few remarks on his criticisms of my interpretation of the term "synthetic organic chemical."

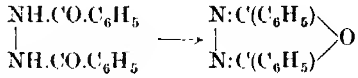
Mr. Kay is mistaken in supposing that I have in any way modified my conception of a synthetic organic compound since discussing the nature of calcium carbide in your columns early last year. On that occasion I stated and considered all the definitions of any authority with which I was acquainted, and quoted finally as much of Posner's definition as was relevant to the carbide case; Posner's whole statement, which occupies about a page, distinguishes carefully between the several types of organic syntheses and receives, I think, the general assent of organic chemists. His whole book deals with the multitude of available synthetic methods for converting organic compounds into others containing new units of constitution, whether these latter contain or do not contain carbon.

It is too late, at the present day, to regard Lieben's defintion as of other than historical importance; the transition from Lieben to Posner became necessary when general reactions for preparing specific types of compounds were being intensively studied, and when analogies between the several reactions of one particular radicle were being traced. Without the transition we could not ask what general synthetic methods are available for the preparation of ethers, because the word "synthetic" would be meaningless in this connexion; further, the combination of acetaldehyde with hydrogen cyanide would be a synthesis, whilst the closely analogous reaction of the aldehyde with ammonia or sodium bisulphite would not be a synthesis. Elbs made it quite clear that the scope of his work was to be limited to a particular class of syntheses, namely, to those in which carbon atoms become joined together; he thus gives no syntheses of organic compounds containing only one carbon atom in the molecule and, indeed, calls attention to the fact that his restricted definition excludes the classical example of organic synthesis which is generally the first placed before the student, that of the conversion of ammonium cyanate into urea. One purpose of my previous article was to show that calcium carbide was a synthetic organic compound in the light of the very restricted definition to which Elbs confined himself, apparently for the purpose of limiting the magnitude of his treatise.

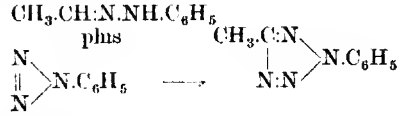
Mr. Kay's attempt to limit Richter's conception of an organic synthesis to cases in which two carbon atoms become joined together or in which carbon compounds are formed from their elements is not justifiable. Richter speaks (*Chemie der Kohlenstoffverbindungen*, 1913, vol. 2, p. 709) of the production of derivatives of furfurane, thiophen and pyrrolidine from γ-diketones and from mucic acid as syntheses; in these reactions no addition of carbon atoms to the molecule takes place, and no carbon atoms become directly joined together. He also gives the following as syntheses:—

Page 817:





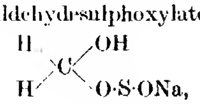
Page 830:



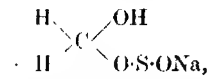
In none of these syntheses do carbon atoms become joined together, and in each case the synthetic process involves the shedding from the molecular complex of weighty scaffolding in the shape of certain components. The common element in the modern definitions of Richter, Posner and others lies in the association of a synthesis with the creation of a unit of molecular constitution not previously present; I submit that Mr. Kay has produced no argument in impeachment of this statement.

We may now pass from the general question to the particular one which gave rise to this correspondence. Mr. Kay appeared in support of an application to delete sodium formaldehydesulphoxylate from the Board of Trade list of substances covered by the Safeguarding of Industries Act, 1921, the chief contention in support of the application being that this substance is not a synthetic organic chemical. For the purpose of revealing the slender grounds upon which the application was based it will suffice to describe the preparation of sodium formaldehydesulphoxylate, and to state the chemical points raised in the cases presented respectively for its removal from, and for its retention in, the Board of Trade list. Of course, sodium formaldehydesulphoxylate differs widely in type of constitution and in modes of preparation from calcium carbide, and an argument applicable to the one substance becomes meaningless when applied to the other.

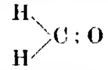
Sodium formaldehydesulphoxylate,



is obtained by the reduction of sodium formaldehyde bisulphite,



which is prepared by the interaction of formaldehyde,



and sodium bisulphite, $NaHSO_3$.

The case argued by Mr. Kay and his friends for the expulsion of sodium formaldehydesulphoxylate from

the Board of Trade list of synthetic organic chemicals premised that the substance is an "additive compound" of formaldehyde and sodium sulphoxylate, HO·S·ONa, notwithstanding that the latter salt cannot be prepared and that no reason exists for assuming its formation during the reduction of the formaldehyde bisulphite compound. In support of the case the chief expert witness gravely informed the learned referee, concerning sodium formaldehydesulphoxylate, that "it would be as correct to say it is organic as to say that it is inorganic. It is not correct to say that it is either," and, further, that "nobody in his sane senses could say whether it is either inorganic or organic"; it was also stated that sodium bisulphite is "a typical inorganic non-synthetic chemical." Further chemical evidence just as helpful as the above was given.

The case for the Board of Trade argued that chemical compounds cannot be classified as organic, inorganic and "hybrid," but that only the first two classes are distinguished by chemists; on this ground sodium formaldehydesulphoxylate can only be regarded as an organic compound. Further, that during the process of using formaldehyde and sodium bisulphite, with zinc as a reducing agent, to produce the organic sulphoxylate, the characteristic properties of the aldehyde and the sulphite disappear; an entirely new constitutional unit is produced by a synthetic process which falls within the modern definition considered above.

The learned referee decided in favour of the Board of Trade, and it is probably unnecessary for me to expand the above very brief summary of the chemical side of the proceedings in order to convince my chemical colleagues that the decision was entirely justified.

Mr. Kay moralises at some length on the unsatisfactory character of the proceedings under the Safeguarding of Industries Act, and concludes by putting four questions to which I may be allowed to give at least partial answers. The answer to question 1 is that the Government did not accept proferred advice; possibly no one foresaw how much ingenuity would be exercised for the purpose of defeating the obvious and simple purpose of the Act. The answer to question 3 is that no court of honour has been, nor probably can be, established in any profession with both legislative and advisory powers concerning professional ethics; the individual who counsels costly legal proceedings on a chemical matter without seeing a perfectly clear and logical road to success is judged by his own firm and by the chemical fraternity in general. To question 4 it may be replied that far too much is said nowadays about the humiliating state of affairs in chemistry; the position of the chemist in the public eye is far higher than it has ever been before.

Mr. Kay's question 2 I leave to the last. It involves a statement which I believe to be quite incorrect; the atmosphere of the law courts may be heating to the witnesses, but it is not sultry to counsel and it certainly does not perturb the tribunal. Few counsel and fewer judges have the instinctive knowledge of a technical subject which should be possessed by an expert witness, and they thus tend unwittingly to divert him from his true function and to assign to him advocative functions; I have more than once been asked to state my views on some particular subject when the proper request would have been that I should state the facts and point the logical conclusions, so that the court might itself digest the evidence and form a view. The difficulty thus indicated is doubtless inherent to the absence of the technical assessor whose appointment I have previously suggested; at the same time, it would not be easy to over-estimate the patience, the care and the intelligence which the President of the tribunal devotes to the hearing of these technical cases. I have described the proceedings in certain of these Board of Trade hearings as "an orgy of misinterpretation and misrepresentation," and I see the description still justified by the statement of an expert witness that "nobody in his sane senses could say whether it (sodium formaldehydesulphoxylate) is either inorganic or organic."

In conclusion I protest against Mr. Kay's suggestion that such a term as "synthetic organic chemical" is not interpretable in purely scientific terms, and that accepted commercial usage should be taken into consideration in this connection. A "synthetic organic chemical" can only mean a "synthetic organic compound," and neither expression has or ever has had any commercial usage; it is a purely scientific conception and must be interpreted as such. Similarly no scientific man, speaking as such, ever uses the phrase "fine chemical"; he cannot be quoted as an authoritative exponent of whatever meaning attaches to this term.

AN ANTHOLOGY OF VERSE RELATING TO SCIENCE

Sir,—During the past five years, I have been collecting verse, whose subject matter relates to the sciences, with the intention of publishing at some future date an anthology of this sort of verse. It has occurred to me that the readers of the *Journal* might be willing to help me in collecting this sort of poetry, in order to make such an anthology of the greatest value, and to this purpose I am writing to you to ask you to insert in the *Journal* this appeal for assistance and co-operation in gathering together this sort of verse. Verse of all moods and forms, provided that its subject matter relates to the sciences, will be welcomed. Contributions sent to C. E. Ruby, Mass Inst. of Technology, Cambridge, Mass., U.S.A., will be duly acknowledged. I am, Sir, &c.,

C. E. Ruby

Cambridge, Massachusetts

At the twenty-first convention of the Institute of British Foundrymen at Newcastle, Mr. John Shaw, of Sheffield, was presented with the Institute's gold medal for the most distinguished member.

PERSONAL AND OTHER ITEMS

The General Board of Studies of Cambridge University has reappointed Mr. F. W. Dootson, University lecturer in chemistry, and Mr. W. H. Mills, University lecturer in organic chemistry.

At a dinner held at the Guildhall in connexion with the Empire Mining and Metallurgical Congress, Prince Arthur of Connaught, at the request of Sir John Cadman and Mr. H. M. Morgans (presidents of the Institution of Mining Engineers and of the Institution of Mining and Metallurgy, respectively), presented medals to Prof. H. Louis and to Mr. H. W. Gepp, who also received a medal for Mr. G. Rigg.

On October 4, Dr. F. W. Aston is to give a lecture on atoms and isotopes before the Swiss Society of Natural Sciences at Lucerne, on the occasion of its 150th annual meeting.

Mr. J. E. P. Wagstaff, M.A., has been appointed professor of physics in the University of Leeds.

Mr. R. C. Richards, B.A., M.Sc., has been appointed Quain lecturer in physics in University College, London.

Sir Jeremiah Colman has given £2000 to establish a library for the School of Biochemistry in the University of Cambridge.

Mr. C. H. Hamilton has been appointed Chairman of Wm. Gossage and Sons, Ltd., in succession to Mr. John Gray, who has been compelled to resign owing to ill-health. In connexion with the retirement of Mr. Gray, Lord Leverhulme, on behalf of the board of Wm. Gossage and Sons, Ltd., and Mr. Gray's former colleagues at Port Sunlight, presented him with a handsome solid silver tea service and tray. Mr. J. A. Sterling, secretary of the company, also presented to Mr. Gray, on behalf of the senior managers of the company, a solid silver fruit and cake stand.

Salters' Institute of Industrial Chemistry

The Committee will, in July, allocate a limited number of Grants in Aid to young men and women, employed in chemical works in or near London, who desire to extend their education for a career in chemical industry. Applicants must not be under seventeen years of age. Applications, with particulars of age, nature of employment, and manner in which the grant would be used, and giving the name of some person to whom reference may be made, should be sent, as soon as possible, and in any case not later than June 14, 1924, to the Director of the Institute, Salters' Hall, St. Swithin's Lane, London, E.C. 4.

Chemical Workers' Wages

The award of the Industrial Court on the chemical workers' application for higher wages (*cf. Chemistry and Industry*, May 30, 1924), has now been issued. The Court has awarded that the wages of adult male time-workers shall be advanced 5d. a day or shift; of adult female time-workers, 4d. a day or shift; and that piece-workers shall receive equivalent advances. The decision states that the claim regarding week-end work has not been established. According to the *Manchester Guardian*, the award affects 22,000 workers, of whom 5 to 7½ per cent. are piece-workers.

Explosives in Canada

The report of the Explosives Division of Canada for the calendar year 1923 shows an improved condition in the industry. The increased production of blasting explosives, as compared with 1922, has been 25 per cent., while the detonator output has increased 48 per cent. Thirteen explosive factories were operating and during the year no employee or other person was injured by an explosive accident. The total accidents arising from the use and abuse of explosives were 183, with 43 killed and 164 injured, and of these 60 occurred in mines and quarries, causing 11 deaths and injuring 61 persons. The accidents attributable to railway, road, building and canal construction, farm clearing, etc., were 48 with 23 lives lost and 31 injured. Other accidents arising from explosives, such as playing with detonators and explosives, in which children are the principal victims, and other miscellaneous causes, were responsible for 75 accidents with 9 deaths and 72 injured. The production and importation of explosives for 1923, as well as the list of authorised explosives, are given in the report. All explosives on the British authorised list are provisionally authorised in Canada.

Australian Exports of Minerals and Metals in 1923

The Imperial Mineral Resources Bureau has received the following statistics from its corresponding member in Australia relative the exports of metals and minerals from Australia during the year 1923:

Exports (in long tons) 1923
(subject to correction)

Metal or Mineral	To British Empire	To Foreign Countries	Total
Copper, refined	6533	700	7233
,, blister	921	1372	2293
,, ore	277	—	277
Pig and antimonial lead	73,189	22,676	95,865
Lead bullion	4461	—	4461
,, ore and concentrates	695	25,638	26,333
Zinc (spelter and elec. zinc)	5076	27,784	32,860
Zinc concentrates	98,142	236,736	334,878
Cadmium	57	4	61
Tin, refined	1433	1432	2865
Mica	180 lb.	—	180 lb.
Antimony ore	379	50	429
Cobalt ore	798	16	814
Alunite	2180	—	2180
Asbestos	65	2	67
Osmiridium	333 oz.	176 oz.	509 oz.
Molybdenum concentrates	8	8	16
,, ore	—	2	2
,, metal	12	16	28
Arsenic	420	140	560
Auriferous antimony ore	127	—	127
Gold concentrates	55	—	55
,, containing platinum	17 oz.	—	17 oz.
,, in concentrates and ores	2611 oz.	47 oz.	2658 oz.
Platinum	170 oz.	21 oz.	191 oz.
Steel	62	27	89
Tantalite ore	3	—	3
Wolfram	13	64	77
,, concentrates	—	20	20
Plumbago	6	—	6
Silver, refined	435,199 oz.	—	435,199 oz.
,, in ore and concentrates	71,751 oz.	—	71,751 oz.

REVIEWS

General Chemistry. By H. G. Deming. Pp. xii+605. London: Chapman and Hall, Ltd., 1923. Price 17s. 6d.

In this book by the Professor of Chemistry in the University of Nebraska we have the outcome of an attempt to present an elementary survey of general chemistry, "emphasizing industrial applications of fundamental principles." It is evident that a vast amount of labour has been incurred, and that much thought has been expended in the effort to realise the stated aim. The result is a book which certainly has a very distinct individuality, and which, for that reason, will interest those who are charged with the duty of selecting a text-book for their students. The author, discussing the various ways in which general chemistry is now handled by University teachers, states that his own desire has been to give his book flexibility, so that it may be used by instructors in a way to meet their own individual ideas and needs in teaching. He takes credit for omission of excessive detail in order to gain space for the "development of such topics of lively interest as hydrogen ion concentration and its applications, an introduction to the chemistry of nutrition, electro-chemical principles and the constitution of matter."

Anyone who has to face the difficulty to-day of conducting an introductory course of chemistry in a University will feel indulgently towards every writer who makes an earnest effort to produce a book for his students. The growth of the science in the detail of new, important fact, the vast development on the physical and industrial sides, compel a constant readjustment of one's ways and a jettisoning of old contents to make room for the new. The last six years, in which there has been so much disturbance at the very foundation of the science, have been particularly tumultuous in this respect, and Prof. Deming's book seems to reflect the condition of chemical unrest. The very typography seems affected by it, for we have not only a differentiation into large and small type, but the interjectory use of heavy type for paragraph headings and for words and statements that are considered specially important.

The contents are divided into three parts:—

(1) "Preliminary," in which oxygen, hydrogen, water, chlorine, and a large amount of general theory are included;

(2) The Non-Metals, comprising further sections of general theory, as well as a certain amount of organic chemistry and a chapter on nutrition;

(3) The Metals.

Interspersed throughout are numerous references to industrial processes, and the book abounds in illustrations and schematic diagrams.

There is no doubt that Prof. Deming has broken away from the orthodoxy that so long ruled the elementary text-book of chemistry, and that in itself commands the reviewer's sympathy. But when we come to look for an educational plan or a rational sequence in his treatment of the subject, it is very difficult to find anything that can be formulated. On the contrary, the book seems, indeed, to be somewhat disjointed and breathless, especially in its exposition of theory. For example, on page 40, where valence is first dealt with, it is said that by the valence of an element we mean the number of atoms of hydrogen that one atom of the given chemical can *combine with* or *displace*." On page 136, we find, in equally heavy type, that "the valence of any element in the uncombined condition is assumed to be zero." This comes of a discussion of positive and negative valence, and is in advance of a brief reference to the structure of the atom on pp. 170—173. It is difficult to believe that the student will not be confused by this treatment.

The author has given his own turn in many cases to definitions and statements, but we cannot say they appear specially felicitous. On page 8 a molecule is described as "a group or cluster of atoms combined in a definite way," and on page 12 we have, under the heading of physical and chemical change, the statement that "any change in a substance which fails to alter its chemical composition and chemical properties is called a physical change." On page 110 we are told that "a sixteenth part of the oxygen atom is taken because the weight of the lightest atom, hydrogen, then turns out to be a trifle over one." The law of multiple proportions is called the "law of related composition."

These instances would not have been adduced were they not thought to be fairly illustrative of a character that pervades the book on the theoretical side. It is more agreeable to close on a note of praise, and to say that there is much in Prof. Deming's book that will be suggestive to chemical teachers, and that he has done especially good service in exhibiting the applications of chemistry to industry and other phases of human life.

Arthur Smithells

A Dictionary of Applied Chemistry. By Sir Edward Thorpe, C.B., LL.D., F.R.S., assisted by eminent contributors. Vol. V. Oxygen-Rye. Revised and enlarged edition, Pp. viii+722. London: Longmans, Green and Co., 1924. Price 60s. net.

The arrival of each new volume of this revised Dictionary arouses the same feeling and impels one to use the same words. The first thought is always of the labour imposed on the Editor, and of the sustained pace and standard of his achievement. We feel that our mission hardly goes beyond that of congratulating Sir Edward Thorpe and of offering our acknowledgments for each instalment of the Dictionary. Those who have ever contributed even a mite to the contents of a volume will know what vigilance and critical care are exercised by the Editor, and will be left with no doubt as to the thoroughness of revision. Once the form and plan of a Dictionary have been determined and its course has begun, there is hardly scope for criticism of a general kind, and, on the other hand, any adequate review of the contents is impracticable.

The present volume begins with Oxygen and ends with Rye. Looking through the list of contributors we find a fine warrant of authority for the chief articles, and here and there a reminder of the topics

that are new or have acquired increased importance in the last few years. A comparison of the present volume with the corresponding one of the preceding edition, however, does not reveal many major changes. It is perhaps not superfluous to remark upon the liberal interpretation which Sir Edward Thorpe gives to the term "Applied Chemistry," for this leads to the inclusion of a large element of theoretical matter which must be of interest and value to all chemists. This may be illustrated by a new article on Photo-Synthesis and Phyto-Synthesis by Professors Baly and Heilbron, as well as by many older ones that reappear. General technological questions are also discussed in such articles as that on Electrical Precipitation by Dr. H. J. Bush. When the chemical elements appear, as in the case of Phosphorus, Platinum, and Potassium, the general chemistry and chief compounds as well as the more strictly technological side are dealt with. The wide chemical appeal strengthens the position of the Dictionary as a standard work that will be looked for in every serious chemical library.

Sir Edward Thorpe is now nearing the completion of his task, and we are sure that all chemists will wish him well through the latest of the unceasing and multifarious labours which he has devoted for more than half a century, to the service of chemical science.

ARTHUR SMITHELLS

DIE FABRIKATION DER MARGARINE. By DIREKTOR P. POLLATSCHEK. Monographien aus dem Gebiete der Fett-Chemie, edited by Prof. K. H. BAUER. Vol. IV. Pp. 52. Stuttgart: Wissenschaftliche Verlagsgesellschaft m.b.H., 1923. Price bound, 2·20 marks, paper 1·80 marks.

This little work constitutes a brief essay on the manufacture of margarine, commencing with a short description of the raw materials used, including fats and auxiliary substances. Milk, which is of such vital importance to the margarine-maker, is discussed and, although in so short a work it is impossible to deal with so extended a subject adequately, a good idea is given to the reader of the quality of milk desirable and the method of treatment. Illustrations and descriptions of well-known margarine plant are given, and methods of manufacture of both animal and vegetable margarine are well described, including notes on methods of packing and distribution. Finally, the legal requirements as to margarine in various countries are contrasted, and a useful bibliography is appended. The pamphlet is undoubtedly of value to those who may require a brief and general survey of the art with information as to where further knowledge may be found.

E. R. BOLTON

Prof. W. L. Bragg, Langworthy professor of physics in the University of Manchester, is to give two courses in the summer session of the University of Michigan on X-ray crystal analysis and recent contribution in the field of X-rays and their interpretations.

COMPANY NEWS

DUNLOP RUBBER CO., LTD.

The profits for the eighteen months to December 31, less depreciation and after charging to reserve losses on forward contracts over market prices arising during the period, were £1,915,608 (£1,054,683 in the ten months to June 30, 1922). Debenture, income stocks, and loan interest totalled £463,816, leaving a net profit of £1,451,792. This is after providing for the preference dividend of No. 2 D. R. Cotton Mills (£86,363), but excluding the deficit of the American Co. for 1923, amounting to £383,179. This amount will be dealt with by the reconstruction scheme. The bankers' debt of £2,019,978 at June 30, 1922, has been discharged, and the company had on hand at December 31 cash and bills, War Loan, and bonds amounting to £1,024,405. Selling prices have been excessively low, chiefly owing to foreign competition. Further concentration of manufacture at Fort Dunlop is in progress. The rubber estates are stated to have shown a satisfactory profit. The French mills have attained a higher output. The German factory is stated to have been a source of continued anxiety, but it is hoped with the continued stabilisation of the rentenmark, to show a profit in the current year. The sales of the American factory are increasing. At the general meeting on June 16, the scheme for the reorganisation of the capital and for dealing with the preference arrears will be submitted.

UNITED PREMIER OIL AND CAKE CO., LTD.

The net profit for 1923 was £86,320 (against £90,649 in 1922), before providing for debenture interest (£22,855, against £23,301). The preference dividend takes £34,431 and a dividend of 5 per cent., less tax, is proposed on the ordinary shares (the same). The balance to be carried forward is slightly in excess of the amount brought in at £20,723.

BLEACHERS' ASSOCIATION, LTD.

The directors propose a final dividend of 15 per cent., making 20 per cent. for the year to March 31 last (the same as for the preceding year). It is proposed to place £125,000 to general reserve (the same) and £50,000 to superannuation fund (against £50,954), while £371,884 is carried forward (against £361,712).

REPORT

REPORT ON THE INDUSTRIAL AND ECONOMIC SITUATION IN CZECHOSLOVAKIA, FEBRUARY, 1924. By E. C. D. RAWLINS, Commercial Secretary, Prague. Department of Overseas Trade. Pp. 42. H.M. Stationary Office, 1924. Price 1s. 6d.

At the commencement of 1923 Czechoslovakia was faced with the economic problems raised by the sudden appreciation in value of the krone (*cf. Chem. and Ind.*, 1923, 1118). At this period the principal exports were coal, iron and timber to Germany, but with the complete collapse of the mark in the middle of 1923 such trade became impossible and Germany, which had absorbed 50 per cent. of the country's exports gave up the first place to Austria. The

United Kingdom has since taken the second place from Germany, though the latter country is still the principal supplier of imports. Czechoslovakia is mainly industrial and great efforts are being made to stabilise industries, though foreign competition and lack of markets abroad may cause the failure of some of the smaller enterprises.

Exports in 1923 were valued at K.č 12,517 millions, and imports at K.č 10,127 mill. (£1 = K.č 24 at par; about K.č 155 in 1923) against K.č 18,085 mill. and K.č 12,841 mill. respectively in 1922, when, however, the value of the krone was considerably less. The chief exports to Great Britain were sugar, glass, hides and leather, timber, and textiles, the articles mainly in demand from this country being textiles, iron and ironware, machinery and scientific instruments, colonial goods, and chemical products. Imports from Great Britain decreased considerably in 1923, but it must be remembered that local industries produce most of the classes of goods supplied from here, while some articles imported through Hamburg were probably considered as of German origin.

The steps taken by glass manufacturers have resulted in a remarkable recovery from the state of affairs at the beginning of 1923; in October 98 furnaces were working, the normal number being 138. Sugar production for 1924 is estimated at 9837 t., against the 1913 figure of 12,687 t., but considerably greater than in 1923. Trade in sugar is now unrestricted and farmers are finding its cultivation to pay better than that of wheat. A strike which lasted from August to October had an adverse effect on coal production; the total output in 1923 of hard coal, 11,596,000 t., was 1,600,000 t. greater than in 1922, but that of lignite fell by 2,700,000 t to 16,229,000 t. The iron industry suffered at the beginning of the year from having to dispose of stocks at low prices in order to keep the furnaces going; later the Ruhr occupation caused a big demand for iron, but the collapse of the mark resulted in the closing of the German market. The steel industry had a more favourable year. Export prices were good, better than those ruling inside the country, and the demand increased. Prices decreased in sympathy with the lessening in costs of raw materials, but further changes must depend on currency deflation.

FRENCH POTASH OUTPUT IN MARCH

During March the production of potash salts was 80,164 tons, equivalent to 21,591 t. of K_2O, distributed as follows:—Crude salts, 25,609 t; manure salts, 30,725 t.; manure salts, 10,058 t., and chlorides, 13,772 t. The four shafts of the Kali Ste. Thérèse now working, produced 442,956 t. of crude potash salts in 1923, against 382,000 t. in 1922. Sales were 367,195 t. of crude salts, equivalent to 65,658 t. K_2O. Stocks on December 31, 1923, were 9132 t. crude salts (3300 t. K_2O). During March the production of salt was 110,472 t., compared with 106,002 t. in February.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Business is maintained at a satisfactory level with a fair export business and very steady values.

Acetic Acid, 40% tech. ..	£23 10s. per ton.
Acid Hydrochloric ..	3s. 6d.–6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw. .	£21 10s.—£27 per ton makers' works according to district and quality.
Acid Sulphuric .. .	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations. 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali.. .	£6 15s. per ton. f.o.r. Special terms for contracts.
Bleaching Powder	Spot £11 d/d., Contract £10 d/d 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial	
Crystal . .	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride ..	£5 17s. 6d. per ton d/d.
Methylated Spirit 64 o.p.	
Industrial .	3s. 1d.–3s. 5d. per gallon, according to quantity.
Mineralised .	4s. 2d.–4s. 6d.
Potash Caustic	£30–£33 per ton.
Potass. Bichromate	5¼d. per lb.
Potass. Chlorate .	3d.–4d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake.. ..	£3 10s. per ton d/d.
Soda Caustic, solid .	Spot lots delivered £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals .. .	£5 5s.–£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton, carr. paid.
Sod. Bichromate	4¼d. per lb.
Sod. Bisulphite Powder 60/62% . ..	£18–£19 per ton, according to quantity, f.o.b., 1 cwt. iron drums included.
Sod. Chlorate ..	3d. per lb.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £14 10s. per ton d/d.
Sod. Sulphide cryst. ..	£9 per ton d/d.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt kegs included.

RUBBER CHEMICALS

Antimony sulphide–	
Golden	5¾d.–1s. 1d. per lb., according to quality.

Crimson	1s. 3d.–1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 11d. per lb.
Barytes	£3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide	3s. 9d. per lb.
Carbon Bisulphide	£24–£26 per ton according to quantity.
Carbon Black	6¼d.–6¾d. per lb. Market firmer.
Carbon Tetrachloride	£56 per ton, drums free.
Chromium Oxide, green	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.–6½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	45s. per cwt., barrels free. Dearer.
Lead Hyposulphite	7½d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£15 10s. per ton f.o.r. London.
Sulphur	£10–£12 per ton, according to quality.
Sulphur Chloride	3d. per lb., carboys extra.
Thiocarbanilide	2s. 9d. per lb.
Vermilion, pale or deep	4s. 10d. per lb. Easier.
Zinc Sulphide	7½d.–1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime–	
Brown	£11 10s. per ton d/d. Demand active.
Grey	£19–£20 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.–£9 per ton, according to grade and locality. Market steady.
Iron Liquor	1s. 7d. per gall. 32° Tw.
	1s. 2d. „ „ 24° Tw.
Red Liquor	10d.–1s. per gall. 14/15° Tw.
Wood Creosote	2s. 7d. per gall. Unrefined.
Wood Naphtha–	
Miscible	5s.–5s. 3d. per gall. 60% O.P. Market stiffer.
Solvent	5s. 6d.–6s. per gall. 40% O.P. Fairly good demand but little offering.
Wood Tar	£5 per ton.
Brown Sugar of Lead	£49 per ton.

TAR PRODUCTS

Acid Carbolic–	
Crystals	6½d.–7d. per lb. Demand quiet.
Crude 60's	1s. 9d.–1s. 10d. per gall. Market flat. Only odd lots being offered.
Acid Cresylic, 97/99	2s. 1d.–2s. 2d. per gall. Demand still good. Market firm.
Pale 95%	1s. 10d.–1s. 11d. per gall. Steady demand.
Dark	1s. 8d.–1s. 11d. per gall. Steady business.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil–	
Strained	9½d. per gall. Very quiet.
Unstrained	8½d.–9d. per gall.
Benzole–	
Crude 65's	10½d.–1s. per gall. ex works in tank wagons.
Standard Motor	1s. 4½d.–1s. 6d. per gall. ex works in tank wagons.
Pure	1s. 8½d.–1s. 10d. per gall. ex works in tank wagons.
Toluole–90%	1s. 5½d. per gall.
Pure	1s. 10d.–2s. per gall.
Xylol comm.	2s. 3d. per gall.
Pure	3s. 3d. per gall.
Creosote–	
Cresylic 20/24%	9d.–9½d. per gall. Few inquiries.
Middle Oil / Heavy / Standard Specification	7d.–9d. per gall. according to grade and district. Demand not so strong.
Naphtha–	
Solvent 90/160	1s. 4d.–1s. 5d. Market steady.
Solvent 90/190	1s. 1d.–1s. 2d. Fair business passing.
Naphthalene Crude–	
Drained Creosote Salts	£6–£6 10s. Demand falling off.
Whizzed or hot pressed	£9–£12 per ton. Little business.
Naphthalene–	
Crystals and Flaked	£16–£17 per ton.
Pitch, medium soft	52s. 6d.–57s. 6d. per ton. Market steadier. Few inquiries for forward delivery. Very little business for prompt.
Pyridine–90/160	21s. 6d.–22s. per gall. Demand well maintained.
Heavy	12s.–12s. 6d. More business passing.

INTERMEDIATES AND DYES

Business in dyestuffs has improved slightly during the week.

Deliveries are still only required in very small quantities owing to the desire of consumers to keep stocks down.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	4s. 4d. per lb. 100% basis d/d.
Acid Naphthionic	2s. 4d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 2d.–1s. 3d. per lb. Steady.
Acid Sulphanilic	10d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	7¾d.–8¼d. per lb. naked at works.
Aniline Salts	7¾d.–9d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 19/31° C.	4¾d.–5¼d. per lb. Demand moderate.
m-Cresol 98/100%	2s. 1d.–2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	2s. 1d.–2s. 3d. per lb. Demand moderate.
Dichloraniline	3s. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£75 per ton.
Diethylaniline	5s. per lb. d/d., packages extra, returnable.
Dimethylaniline	2s. 4d. per lb. d/d. Drums extra.
Dinitrobenzene	9d. per lb. naked at works.
Dinitrochlorbenzol	£84 10s. per ton d/d.
Dinitrotoluene 48/50° C.	8d.–9d. per lb. naked at works.
66/68° C.	1s. 2d. per lb. naked at works.
Diphenylamine	3s. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 4½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 4d. per lb. d/d.
Nitrobenzene	5¼d.–5½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.

Nitronaphthalene ..	.. 11¾d. per lb. d/d.
p-Nitrophenol ..	.. 1s. 9d. per lb. 100% basis d/d.
p Nitro-*o*-amido phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine ..	4s. 2d. per lb. d/d.
p-Phenylene Diamine ..	10s. 3d. per lb. 100% basis d/d.
R Salt	.. 2s. 6d. per lb. 100% basis d/d.
Sodium Naphthionate ..	2s. 5d. per lb. 100% basis d/d.
o Toluidine ..	.. 8½d. per lb.
p Toluidine ..	.. 3s. 6d. per lb. naked at works.
m-Toluylene Diamine ..	4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P. ..	£48 per ton.
Acid, Acetyl Salicylic ..	3s. 3d.– 3s. 5d. per lb. In good demand.
Acid, Benzoic B.P.	. 3s. 9d. per lb. Larger supplies available.
Acid, Boric B.P...	.. Cryst. £54 per ton, Powder £58 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric..	.. 19s.—21s. per lb.
Acid, Citric ..	.. 1s. 6½d. per lb., less 5% for ton lots. Market extremely firm. Upward tendency.
Acid, Gallic ..	.. 3s. per lb. for pure crystal. Market very steady.
Acid, Pyrogallic, Cryst ..	7s. per lb. for 1 cwt. lots. Market firm; increasing demand.
Acid, Salicylic ..	.. Prices quoted from 2s. per lb. down to 1s. 9d. for ton lots. Market weak.
Acid, Tannic B.P	. 3s. per lb. Market quiet.
Acid, Tartaric	.. 1s. 1½d.– 1s. 2d. per lb. less 5%. Better tone but not yet very active. Cheap offers of second hand parcels of foreign acid. Higher prices expected in view of firmness of raw materials.
Amidol ..	.. 9s. per lb d/d.
Acetanilide	.. 2s. 3d. per lb. for quantity. Stocks are small.
Amidopyrin	. 13s. 6d. per lb. Neglected. Stocks low.
Ammon. Benzoate	.. 3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	.. 12s. per oz. for English make.
Barbitone .	. 15s. 6d. per lb. Quiet market.
Benzonaphthol .	. 5s 6d. per lb. Small inquiry.
Bismuth Salts .	.. A steady market. Prices according to quantity:
Bismuth Carbonate	.. 12s. 9d.- 14s. 9d. per lb.
„ Citrate .	.. 11s. 4d.- 13s 4d. „
„ Salicylate	. 10s. 2d. 12s. 2d. „
„ Subnitrate	.. 10s. 9d.- 12s. 9d. „
Borax B.P. ..	.. Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides – .	.. Fluctuating market. Continental prices decidedly firmer.
Potassium ..	.. 11d. per lb.
Sodium .	.. 1s. „
Ammonium ..	.. 1s. 1d per lb.
Calcium Lactate..	.. Demand active. Good English make can be had from 1s. 7d. to 2s. 6d. per lb.
Chloral Hydrate ..	.. 3s. 10d. per lb., duty paid. Advanced. Higher prices are quoted from the Continent.
Chloroform ..	.. 2s. per lb. for cwt. lots. Market more active. Makers busy.
Creosote Carbonate	.. 6s. 6d. per lb. Little demand.
Formaldehyde ..	.. £57 per ton, *ex* works. English make.
Glycerophosphates –	Fair business passing.
Calcium, soluble and citrate free .	. 7s. per lb.
Iron .. .	. 8s 9d. per lb.
Magnesium ..	.. 9s per lb.
Potassium, 50%	.. 3s. 6d. per lb.
Sodium, 50% ..	.. 2s. 6d. „
Guaiacol Carbonate	.. 12s. per lb for cwt lots Supplies not plentiful.
Hexamine ..	.. 3s. 9d. per lb. for English make. Market dull.
Homatropine Hydrobromide	.. 30s. per oz.
Hydroquinone ..	.. 4s. 3d. per lb. in cwt. lots. Foreign make.
Hypophosphites –	
Calcium .	3s. 6d. per lb., for 28-lb. lots.
Potassium .	. 4s. 1d per lb.
Sodium .	4s. „
Iron. Ammon. Citrate B.P.	2s. 1d 2s 5d. per lb, according to quantity. Advanced by 2d. per lb.
Magnesium Carbonate –	
Light Commercial	.. £36 per ton net.
Magnesium Oxide –	
Light Commercial	.. £75 per ton, less 2½%.
Heavy Commercial	.. £26 per ton, less 2½%.
Heavy Pure .	. 2s 2s. 3d. per lb., according to quantity. Steady market.
Menthol –	
A B.R. recryst. B P.	.. 60s. per lb. Weaker.
Synthetic ..	. 26s. 35s per lb., according to quantity. English make. Steady demand.
Mercurials	. Market firm.
Red oxide	.. 5s 3d. 5s. 4d. per lb.
Corrosive sublimate	.. 3s. 6d. 3s. 7d. „
White precip.	.. 4s. 7d.—4s. 8d. „
Calomel ..	. 3s. 11d. - 4s. „
Methyl Salicylate	.. 2s. 3d. 2s. 9d. per lb. for carboys. A slightly better market.
Metol ..	. 11s. per lb. British make.
Paraformaldehyde	.. 3s 6d. per lb. Better inquiry.
Paraldehyde	.. 1s. 4d - 1s. 6d. per lb. in free bottles and cases. Better demand.
Phenacetin .	. 6s per lb.
Phenazone .	. 7s 3d. per lb. for cwt lots. Quiet.
Phenolphthalein	.. 6s. 9d. 7s. 3d. per lb. In more plentiful supply.
Potass. Bitartrate 99/100% (Cream of Tartar) ..	.. 88s. per cwt, less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate ..	. 1s. 10d.—2s. 2d. per lb. Dearer.
Potass. Iodide	.. 16s. 8d. 17s. 5d. per lb., according to quantity. Demand continues.
Potass. Metabisulphite	. 7½d per lb., 1 cwt. kegs included.
Potass. Permanganate	
B.P. Crystal ..	.. 8¾d. -9d. per lb. carriage paid.
Commercial .	.. 8d. 8¼d. per lb. carriage paid.
Quinine Sulphate	.. 2s. 3d. 2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin .. .	.. 5s. 6d. per lb
Saccharin. ..	.. 63s. per lb., in 50-lb. lots.
Salol .. .	.. 3s. 6d per lb. Very quiet.
Silver proteinate..	.. 9s. 6d. per lb.
Sod. Benzoate, B.P.	..2s. 6d. per lb. In steady demand for good qualities.
Sod. Citrate, B P.C., 1923	2s.- 2s. 2d. per lb., according to quantity. Much firmer in common with other citrates. Prices advanced by 2d. per lb.

Sod. Hyposulphite Photographic .	£13 £15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst	37s. 6d. 60s per cwt nett cash, according to quantity.
Sod. Nitroprusside .	16s. per lb. Less for quantity.
Sod. Potass Tartrate (Rochelle Salt)	77s 6d. 81s 6d per cwt , according to quantity. Market quiet.
Sod. Salicylate	Market easier. Powder 2s. 3d. - 2s. 6d. per lb. Crystal at 2s. 5d. 2s. 8d. per lb. Flake 2s. 9d.– 2s. 10d. per lb.
Sod. Sulphide Pure recryst . .	10d.- 1s. 2d. per lb., according to quantity.
Sod Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Thymol . ..	15s. per lb. for good white crystal from ajowan seed. Very firm and scarce.

PERFUMERY CHEMICALS

Acetophenone .. .	12s. 6d per lb.
Aubepine .	14s. 6d ..
Amyl Acetate	2s. 9d. ..
Amyl Butyrate .	6s. 9d ..
Amyl Salicylate	3s. 3d. ..
Anethol (M P 21 22 C)	1s. 6d. ..
Benzyl Acetate from Chlorine free Benzyl Alcohol	3s. 3d. ..
Benzyl Alcohol free from Chlorine .	3s. 3d. ..
Benzaldehyde free from Chlorine .	3s. 6d ..
Benzyl Benzoate .	3s. 6d. ..
Cinnamic Aldehyde Natural .	15s. 6d. ..
Coumarin	20s ..
Citronellol .	16s. ..
Citral ..	10s. ..
Ethyl Cinnamate	15s ..
Ethyl Phthalate	3s. 3d. ..
Eugenol . .	11s. ..
Geraniol (Palmarosa)	35s ..
Geraniol .	11s -18s. 6d per lb.
Heliotropine . .	6s 6d per lb.
Iso Eugenol .	15s. 9d ..
Linalol ex Bois de Rose	28s. 6d. ..
Linalyl Acetate . .	28s 6d. ..
Methyl Anthranilate .	9s 6d. ..
Methyl Benzoate .	6s. ..
Musk Ambrette	48s. 6d. ..
Musk Xylol .	16s 6d. ..
Nerolin	4s. ..
Phenyl Ethyl Acetate	12s 6d ..
Phenyl Ethyl Alcohol	16s. ..
Rhodinol .	57s. 6d. ..
Safrol	1s 10d. ..

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition not later than Aug . , they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. on June 19.

I.—Applications

Baker, Perkins, Ltd , and Head. Mixing apparatus 13,239. May 29.

Hailwood. Furnaces. 13,038, 13,039. May 28.

Hess. Regenerative furnaces. 12,988. May 27.

North British Diesel Engine Works (1922), Ltd., and Holloway. Centrifugal separators. 12,854. May 26.

Raymond Bros. Impact Pulverizer Co. Grinding or pulverizing apparatus. 13,265, 13,266. May 29. (U.S., 25-26.6 23.)

Rheinische Maschinenfabrik. Crushing mills. 13,112 May 28. (Ger , 28.5.23.)

I.—Complete Specifications Accepted

5108 (1923). Minimax Ges. Manufacture of foam for fire-extinguishing. (197,295.)

17,871 (1923). Carrier, and Carrier Engineering Co Drying and conditioning materials. (216,381.)

II.—Applications

Baird and Corthesy. Distillation of liquid hydrocarbons 13,261 May 29.

Calvert. Synthetic production of liquid hydrocarbons 13,374. May 31.

Davidson, Mielne, and Electrical Improvements, Ltd Fuel distillation 13,143. May 28.

Gregson, and Spencer-Bonecourt, Ltd. Installations for carbonising coal etc. 13,135 May 28.

Internationale Bergin-Compagnie voor Olie- en Kolen-Chemie. Process of treating carbon and hydrocarbons 13,095. May 28. (Ger., 31.5.23.)

King. Binder for manufacture of briquettes. 12,897 May 26.

Kung. Generating heating flames. 13,336. May 30

Marks (Carbide and Carbon Chemicals Corporation) Partial oxidation of gaseous hydrocarbons. 12,915. May 26

Raymond Bros. Impact Pulverizer Co. Pulverizing, feeding, and burning fuel. 13,264. May 29. (U.S., 8.3 24.)

Toogood. Carbonising plant. 13,170. May 29.

Wade (Streppel). Ovens for distillation of coal etc 13,094. May 28.

II.—Complete Specifications Accepted

35,310 (1922). Terrisse. Preparation of a carburetting fuel-mixture for internal-combustion engines. (216,169.)

722 (1923). Koppers Co. Vertical retort furnaces. (201,130.)

13,000 (1923). Comp. de Bethune. Recovery of the by-products of the distillation of coal. (209,703.)

17,665 (1923). Sutcliffe. Production of carbonised fuel. (216,378.)

19,963 (1923). Cabrier. *See* VII.

20,018 (1923). Fajole. Apparatus for producing semi-water-gas. (202,303.)

25,292 (1923). Barrett Co. Purifying hydrocarbons. (206,481.)

30,644 (1923). Crasoli. Water gas generators. (216,456.)

III.—Application

Baird and Corthesy. 13,261. *See* II.

III.—Complete Specifications Accepted

19,963 (1923). Cabrier. *See* VII.

25,292 (1923). Barrett Co. *See* II.

IV.—Application

Soc. of Chemical Industry in Basle. Manufacture of substantive azo dyestuffs. 13,360. May 30. (Switz., 27.7.23.)

IV.—Complete Specifications Accepted

5465 (1923). Meister, Lucius, u. Bruning. Manufacture of azo dyestuffs. (193,866.)

5731 (1923). Meister, Lucius, u. Bruning. Manufacture of azo dyestuffs. (195,600.)

14,945 (1923). Imray (Soc. Chem. Industry in Basle). Manufacture of naphthoindoxyls. (216,347.)

25,182 (1923). Meister, Lucius, u. Bruning. Manufacture of condensation products of the anthraquinone series. (205,502.)

V.—Applications

Courtaulds, Ltd., and Weyenbergh. Preparation of alkali celluloses. 13,331. May 30.

Courtaulds, Ltd., Bayley, and Hegan. Manufacture of viscose threads etc. 13,335. May 30.

Ges. fur Mechanische Zellulose. Manufacture of unbleached paper, cardboard, etc. 12,882. May 26. (Ger., 25.5.23.)

Ges. fur Mechanische Zellulose. Production of a half-stuff for cellulose manufacture. 12,883. May 26. (Ger., 25.5.23.)

Greenwood and Batley, Ltd., and Holt. Apparatus for spinning artificial silk. 13,383, 13,384. May 31.

Lilienfeld. Manufacture of artificial materials. 13,353, 13,354, 13,356, 13,359. May 30. (Austria, 4.4.24.)

Lilienfeld. Manufacture of cellulose derivatives. 13,355, 13,357, and 13,358. May 30. (Austria, 4.4.24.)

VI.—Application

Beckett, Thomas, and Scottish Dyes, Ltd. Dyeing. 12,914. May 26.

VI.—Complete Specifications Accepted

31,078 (1922). Moseley. Agents or assistants for detersive, scouring, bleaching, dyeing, and like operations. (215,880.)

22,314 (1923). Schlumpf. Apparatus for dyeing, bleaching, etc. (216,415.)

VII.—Applications

Jorgensen. 13,093. *See* IX.

Synthetic Ammonia and Nitrates, Ltd. (Collett). Catalysts for synthesis of ammonia. 13,167. May 29.

Synthetic Ammonia and Nitrates, Ltd. (Collett). Production of hydrogen. 13,168. May 29.

VII.—Complete Specifications Accepted

4873 (1923). Lamoreaux. Making sulphuric acid. (216,192.)

1983 (1923). Marks (Nitrogen Corporation). *See* X.

5286 (1923). Lamoreaux. Manufacture of sulphuric acid. (198,332.)

14,941 (1923). Urfer. Manufacture of catalysts for the synthesis of ammonia. (199,030.)

19,963 (1923). Cabrier. Distillation of ammoniacal liquids, tars, oils, and other liquids obtained in gas-works. (201,935.)

1644 (1924). Kautny. Devices for regulating the evaporation of liquid oxygen and the like. (216,463.)

19,834 (1923). Bass Akt.-Ges. Apparatus for producing anhydrous tin chloride. (201,927.)

IX.—Applications

Campbell, and Hardman and Holden, Ltd. Bituminous preparations, and their use in road making etc. 13,181. May 29.

Hay. Bituminous emulsions. 13,424, 13,425. May 31.

Jorgensen. Process of burning cement, lime, etc., and rotary kiln therefor. 13,093. May 28.

Mulligan. Manufacture of hydraulic cement etc. from gypsum. 13,048. May 28.

IX.—Complete Specifications Accepted

6966 (1923). Meadows. Composition for making or waterproofing roads. (216,245.)

21,391 (1923). Winqvist. Rotating kilns for burning cement etc. (203,673.)

X.—Applications

Baker. Electroplating. 12,917. May 26.

Baker. Method of determining boric acid in nickel-plating solutions. 12,918. May 26.

Brown and Wellesley. Alloys. 13,028. May 27.

Campbell. Manufacture of alloy steels. 13,361. May 30.

Campbell. Heating metal having magnetic properties. 13,362. May 30.

Hedges. Process of educting valuable ingredients from ores etc. 12,914. May 26.

Jackson (Stroman). Method of refining tin etc. 13,216. May 29.

MacKay. Electrochemical treatment of copper ores etc. 13,253. May 29.

Marks (Electro Metallurgical Co.). Welding and brazing copper etc. 12,916. May 26.

Seaton. Protection of metallic surfaces against corrosion. 13,315. May 30.

X.—Complete Specifications Accepted

31,843 (1922). Eureka Metallurgical Co. Flotation processes of recovering values from ores. (194,260.)

35,221 (1922). Edwards and Durant. Treatment of oxidised ores or other oxidised compounds of copper. (216,162.)

1983 (1923). Marks (Nitrogen Corporation). Manufacture of steel and fixation of nitrogen. (216,198.)

5702 (1923). Gordon and Keith. Treating ores etc. (216,228.)

19,283 (1923). British Thomson-Houston Co., Ltd. (General Electric Co.). Alloys. (216,389.)

XI.—Applications

Baker. 12,917. *See* X.

Baker. 12,918. *See* X.

Brown, and Telegraph Condenser Co., Ltd. Insulating and di-electric materials. 13,226. May 29.

Ellis (Roessler and Hasslacher Chemical Co.). Electrolysis. 13,140. May 28.

Jones (Manhattan Electrical Supply Co., Inc.). Dry cells. 13,017. May 27.

MacKay. 13,253. *See* X.

Rennerfelt. Electric arc furnaces. 13,129. May 28.

XIV.—Application

Traube. Production of rubber from latex. 13,267. May 29.

XV.—Complete Specification Accepted

32,214 (1923). Elektro Osmose Akt.-Ges. Manufacture of gelatin suitable for emulsions. (210,748.)

XIX.—Applications

Milner and Munroe. Methods of sterilising and preserving foods. 13,074, 13,075, and 13,076. May 28.

XIX. Complete Specification Accepted

1988 (1924). Thésée. Sterilising-medium. (216,464.)

XX.—Application

Carpmael (Chemische Fabrik auf Actien vorm. E. Schering). Manufacture of compounds of 4 amino-2 argentomercapto-benzene-1-carboxylic acid and alkali salts thereof. 13,345. May 30.

XX.—Complete Specifications Accepted

16,587 (1923) Imray (Meister, Lucius, u. Brüning). Manufacture of ethyl chloride. (216,368.)

26,163 (1923) Poulenc Frères, and Oechslin. Manufacture of oxyethylarsinic acid. (206,143.)

XXI.—Application

Thornton. Non inflammable kinematograph films. 13,192. May 29.

XXI.—Complete Specifications Accepted

21,898 (1923). Kalmus, Comstock, and Wescott, Inc. Photographic developing processes. (204,034.)

32,214 (1923) Elektro Osmose Akt Ges. *See* XV.

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific number:— *Argentina*: Artificial silk (646); *Austria*: Steel (625); White lead, pig lead, oil, chemicals (627); *Belgium*: Phosphor bronze cable (B.X. 1009); *British India*: Lead, steel (Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E. 1); *Canada*: Silk (618); Leather (621); *Chile*: Steel (648); *Damascus*: Silk (643); *Denmark*: Iron and steel (630); *Dominican Republic*: Silk (649); *East Africa*: Agricultural implements (622); *Netherlands*: Sugar (634); *New Zealand*: Hardware (623); Electrically-driven centrifugal pump (A.X. 1001); *Norway*: Leather (638); *South Africa*: Electric lamps (B.X. 1011); *United States*: Hardware (645); *Uruguay*: Copper wire (B.X. 1005).

Further enquiries are as follows: *Argentina*: Tinplate (669); *British India*: Steel, brass (The Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E. 1); *France*: Copper sulphate, sulphur (656); *Morocco*: Hides, skins (665); *Poland*: Perfumes (660); *Rumania*: Galvanised iron wire (A.X. 1025); *Switzerland*: Aluminium (A.X. 1031); *South Africa*: Silk (652); *Turkey*: Agricultural machinery (A.X. 1028); *Venezuela*: Earthenware (673).

Dyestuffs (Import Regulation) Act, 1920

The following statement relating to applications for licences under the Dyestuffs (Import Regulation) Act, 1920, made during May, has been furnished to the Board of Trade by the Dyestuffs Advisory Licensing Committee.

The total number of applications received during the month was 596, of which 491 were from merchants or importers. To these should be added 32 cases outstanding on May 1, making a total for the month of 628. These were dealt with as follows:—

Granted—476 (of which 429 were dealt with within 7 days of receipt).

Referred to British makers of similar products—136 (of which 117 were dealt with within 7 days of receipt).

Referred to Reparation Supplies available—7 (all dealt with within two days of receipt).

Outstanding on May 31, 1924—9.

Of the total of 628 applications received, 553 or 86 per cent. were dealt with within 7 days of receipt.

Trade Information

The Dorr Company, Engineers, of New York, announces that its continued growth has required a further expansion of the Executive Department. Mr. J. V. N. Dorr, President and General Manager since the foundation of the company, has appointed Dr. R. B. Moore, at present head of the Development Department, as General Manager. Mr. H. N. Spicer, of the Executive Staff, will sail on June 4 to London, as the first step of a tour of Europe that will take from four to six months, and will cover practically every important industrial section of the Continent. Mr. Spicer will make a special business survey, both in a general way and in connexion with the Dorr Company's European business. He will make his headquarters in London, at 16, South Street, E.C., but will spend most of his time in Spain, Italy, Austria, Czechoslovakia, Poland, and Germany.

French Company News

The Société des Mines de Dourges lit two new batteries, each of 42 coke ovens in August and October, 1923, and a third battery of 50 ovens is now ready, and a fourth of 50 ovens is under construction. To ensure complete use of by-product gas and tar the company has acquired interests in the Société Ammonia and in the Société Huiles, Goudrons et Dérivés, and will shortly begin to build a synthetic-ammonia plant. The company will also share the use of a tar distillery at Vendin le Vieil, which will be provided with ample plant for the manufacture of a range of tar products.

The Société de Pechelbronn is now producing at the rate of 3600 metric tons of crude oil a month. The company's refinery is working satisfactorily, and the more valuable products are now being obtained in larger proportion.

PUBLICATIONS RECEIVED

The Specific Heats of Gases. By J. R. Partington, M.B.E., D.Sc., and W. G. Shilling, M.Sc. Pp. 252. London: Ernest Benn, Ltd., 1924. Price 30s.

A Short History of Chemistry. By Rose Stern, B.Sc. Pp. viii+149. London: J. M. Dent and Sons, Ltd., 1924. Price 2s. 6d.

Mechanical Refrigeration. By Hal Williams. A practical study of cold storage and ice making in all their aspects. Revised edition. Pp. x+501. London: Sir Isaac Pitman and Sons, Ltd., 1924. Price 20s.

JOURNAL of THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 43 NEW SERIES LONDON, JUNE 20, 1924 No. 25

EDITORIAL

WE have received from Prof. Bancroft a reprint of a paper on the Action of Metals on Nitric Acid, published in the *Journal of Physical Chemistry* in May this year. This gives copious extracts from the statements in sundry books and papers on this topic, and a critical examination of them. Different writers have considered the reduction of nitric acid by metals, by hydrogen and by metallic nitrates, without arriving at unanimity. Although the main features are known to all chemists, the principles are only now being made clear and a survey of the work is of great value. Prof. Armstrong about forty-seven years ago made some experiments on the effect of metals on nitric acid: he concluded that these formed nitrates in the usual manner and that the hydrogen produced by the change reduced the nitric acid to nitrous acid, hyponitrous acid, hydroxylamine and ammonia, or some of these, in proportions depending upon the metal employed and other circumstances. Several years later came the theory of ionic dissociation, and the suggestion by Ostwald that nitric acid in presence of a metal splits up into the ions $\cdot$HO and NO_2, and that the various products obtained when a metal is dissolved in nitric acid are the secondary compounds resulting from the interaction of these ions and others. Armstrong's views about the dissociation hypothesis are well-known; how often has he told us, "I know not if in others' eyes it seem'd almost divine, but far beyond a doubt it lies that it did not in mine." Thereafter many experiments were made on metals and nitric acid, but according to Bancroft, each chemist merely used to "smile and look politely round to catch a casual suggestion, but made no effort to propound any solution of the question." Bancroft has long pondered over the problem, and with the assistance of Mr. Milligan he thinks he has got on the right track: new methods of analysis have been devised, and we are promised shortly an account of the reactions which indeed are complex and affected by a number of variables. Already he confirms Armstrong's 1877 account, and his full memoir will be awaited with interest. Does not this piece of work show how many opportunities for research are close at hand, and "what man might be, would he but do the duty that lies near, and cut clubs, cards, champagne, balls, billiard-rooms and beer?" This quotation would perhaps make a suitable motto for No. 2, Whitehall Court.

There are many other problems concerning the commonest reagents awaiting explanation. Does ammonium hydrate exist? The statements about this material are singularly conflicting, and an exact knowledge of the behaviour of such substances as nitric acid, ammonia and water would be of the greatest benefit to us all.

* * *

The Annual Meetings of the International Union of Pure and Applied Chemistry have been so delightful and valuable that those who have participated in them have hitherto avoided any criticism. A correspondent who has attended several of these meetings directs the attention of chemists to some matters which require serious thought. We well remember the early meetings in Paris and London which laid the foundations of the International Union, and we think the most sanguine of those who were present did not expect the steady and rapid success which has been attained. A constitution and a method of conducting the business of the Union were devised, admirable for a young society whose numbers were comparatively small. Prof. Moureu, the first president of the Union, worked so hard during his term of office that the Union has now become large, expensive, important and cumbrous. Sir William Pope, now president, is proceeding along the path marked out by his predecessor and, in the opinion of some, it will

only be a question of a few months or possibly a couple of years before the Union Internationale will begin to pay the penalty for rapid and abundant success. An army cannot march with the speed and ease of a regiment or a squadron. It must be content with many restrictions; nevertheless, it goes further and accomplishes more. The importance of its decisions are so great and the consequences so serious that many must be consulted and much time spent. The little squadron which Moureu commanded has already grown to the dimensions of a brigade and threatens to become a division. It may be worth while to consider whether its original conception is still adequate for effective working and we have heard from two or three chemists whose opinions are of value that the time is ripe for an effort to make its organisation and methods more suitable to its present dignity and importance. That such opinions can be held so soon after the foundation of the Union is a striking testimony to the sturdiness of its growth and to the tact and enthusiasm displayed by the Bureau and officials of the Union.

* * *

A teacher criticises the price of "Chemistry in the Twentieth Century." This book is a handsome production of some 280 pages, well written, well printed, and with some excellent illustrations; it costs 15s. net. We have compared it with some recent chemical and engineering books published by Messrs. Blackie and Son, Sir Isaac Pitman and Sons, Ltd., Messrs. Charles Griffin and Company, Ltd., John Wiley and Sons, Inc., Messrs. Longmans, Green and Co., and Macmillan and Co., Ltd., and think that taking everything into consideration this is a cheaper book than the average high-class scientific book published during the last two years. We are informed, and verily believe, that the contributors to this book did their work gratuitously, that knowledge might be increased, and that if they had been paid for their contributions, either what these are worth, or what it is usual to pay Fellows of the Royal Society and Knights of the Shire, the cost of the book would have considerably exceeded the 15s. fixed by the publishers in consultation with the Association of British Chemical Manufacturers. This Association is composed of acute business men, and it is quite possible that no other organisation could have made so satisfactory a bargain. The book, admirable as it is, is not intended for the junior members of the chemical fraternity; for these a set of pamphlets has been prepared at the price of sixpence each, and a considerable number has been sold at Wembley and elsewhere. The Association of British Chemical Manufacturers has catered for two important classes, there is, we admit, an intermediate class for which many books are published at different prices. During the last few years several chemical treatises have been published at prices between a shilling and ten shillings. Why—to travesty Courteline—should anyone pay seven or eight shillings for an umbrella when he can get "Chemists and Their Work" or *Chemistry and Industry* for sixpence!

A SIMPLE DEDUCTION OF THE LAW OF SOLUBILITY PRODUCT

By J. A. V. BUTLER, M.Sc.

The old deduction of the law of solubility product which is given in practically all textbooks of physical chemistry rested on the application of the law of mass action to two equilibria. In the first place it was assumed that the concentration of undissociated salt in solution was proportional to the "active mass" of the solid, *i.e.*, that the undissociated molecules had a definite solubility. Secondly the law of mass action was applied to the equilibrium between the undissociated salt and its ions. Thus representing concentrations in square brackets,

$$[MX]=k_1\,[MX]_{solid}$$

$$\frac{[M^{\cdot}]\times[X']}{[MX]}=k_2$$

$$\text{Therefore } [M^{\cdot}]\times[X']=K.$$

The incorrectness of both of these applications is now beyond dispute. The extensive researches of Noyes and others (*J. Amer. Chem. Soc.*, 1911 *et seq.*) proved that the concentration of undissociated salt (as determined by conductivity measurements) is certainly not constant. It was realised almost from the first that the law of mass action does not apply to the equilibrium between a salt and its ions.

Most teachers have probably felt the unsatisfactory nature of this treatment. But the relation had to be deduced somehow even if the inadequacy of the proof was so glaring as to make it necessary to apologise for it in elementary classes. It is scarcely productive of a proper respect for a subject to have to make apologies of this sort and it is thought that a simple deduction which is free from these objections and sufficiently elementary for beginners may be of interest.

This deduction is based on the more elaborate statistical treatment recently given by the writer (*J. Phys. Chem.*, 28, 438, 1924). It assumes that the ions of a simple salt take part independently in the process of solution at the crystal surface. Modern knowledge makes this conception inevitable. If the salt is almost or entirely dissociated into ions in solution, and if the solid crystal is rightly regarded as a lattice structure built up of positive and negative ions, there is no reason to postulate the appearance of the molecule at any stage in the process of solution.

An ion leaves the surface and passes into solution when it has acquired by thermal agitation sufficient energy to carry it out of the range of the attractive forces at the crystal surface. An ion becomes deposited when it reaches the surface from solution at a place at which it can become permanently attached. In the simplest case of a cubic lattice a positive ion must be deposited above a negative one and *vice versa*, in order to continue the crystal lattice. It follows that the rate at which an ion leaves the surface is proportional in the first place to the number in the surface layer, whilst the rate of deposition of an ion is proportional to its concentration in solution and to the number of places at the surface at which it can become attached.

Equilibrium is attained when equal numbers of both kinds of ions are dissolved and deposited in the same time.

Now consider the state of the crystal surface in contact with the solution. Take the case of a crystal normally containing equal numbers of positive and negative ions in its surface layer. In contact with solution there may be a greater tendency for the one ion to leave or to become deposited at the surface than the other. The facility with which precipitates of insoluble salts adsorb a common ion is well known. Fajans and Frankenburger (Z. phys. chem., **105**, 255, 1923) have recently determined the amount of silver ion adsorbed by silver bromide crystals and found for one particular dilute solution an adsorption of one silver ion for every four to ten bromide ions of the exposed surface.

The result may be roughly illustrated as follows: I shows a cross-section of the two layers next to the surface of a complete crystal; II the same for a crystal with an incomplete surface layer which has lost more positive than negative ions.

I

− + − + − + − + − +
+ − + − + − + − + −

Exposed, 5 +, 5 −.

II

− +   + − + − + − +
− + −   −

Exposed, 3 +, 5 −.

It is evident that the loss of a positive ion exposes a negative ion and *vice versa.*

Suppose that at equilibrium Nx positive ions and N (1 − x) negative ions are exposed at the surface. Then we can write the following proportionalities:—

Rate of solution of positive ions = k_1Nx,
Rate of deposition of positive ions = $k_2N(1 - x).C_1$,
Rate of solution of negative ions = $k_3N(1 - x)$,
Rate of deposition of negative ions = k_4NxC_2;
where C_1 and C_2 are the concentrations of the positive and negative ions in solution.

For equilibrium

$$k_1Nx = k_2N(1-x)C_1$$

and

$$k_3N(1-x) = k_4NxC_2$$

whence

$$C_1 \cdot C_2 = \frac{k_1k_3}{k_2k_4} = K$$

which is the law of solubility product.

It is evident that if the addition of electrolytes whether containing a common ion or not causes any change in the conditions of solution (*e.g.*, by affecting the attraction of the solvent for the ions), the quantities k_1, k_2, etc., will not remain constant. The fact that the "law" is at best an approximation need cause no surprise. Some of the factors affecting the solubility product have been discussed from this point of view in the paper referred to.

University College of Swansea

ABSORBENT AND DECOLORISING CARBONS

By E. R. SUTCLIFFE, Wh.Ex., A.M.I.M.E.

In view of the interest now being taken in absorbent materials generally the following notes on carbons made at Leigh will be of interest.

These carbons are a development of work done during the war when it was found necessary to have some more highly active material than the charcoal then in use, and, furthermore, to render the country less dependent upon expensive foreign carbons.

It was then found that by the briquetting and carbonisation of coal a special structure could be produced, and that by suitable slow oxidation this structure could be deepened and rendered quite as active for absorbent purposes as any of the then known absorbent carbons, so material was then produced and supplied to the Anti-Gas Department of a power some seven or eight times more active than that then in general use.

On the termination of hostilities a large installation for the production of this highly active material was in course of construction, and it is in adapting this plant and invention to peace purposes that Sutcliffe, Speakman and Co., Ltd., have now turned their energies.

Further research showed that the carbon manufactured under the process was not only of high absorptive power, but that by modifying the process the highest qualities of carbon for decolorisation could be made, and in recent developments carbon has been made equal and in some respects superior to the highest quality of zinc-activated foreign carbon.

Absorbent Carbons

Absorbent carbons are made in many forms and qualities, and the development of grading and quality will depend largely upon demand and the purposes that open up for their use. An advantage in the carbon made under the process is that it can be made in any grade from sizes 2½ in. to the familiar 6 to 12 in. mesh, or if required special shapes of block carbon can be made.

No universal standard for absorptive power is adopted at present, but the highest qualities are quite equal to the highest quality of activated coconut char, and in small quantities material of super-activity has been made. The highest quality is suitable for gas masks, and for an absorbent for the more expensive solvents. A lower grade is more suitable, say, for benzol recovery at gas works or oil works. Other grades of less costly carbons are available for use in treatment for water purification, such as treating chlorinated water, or for extracting naphthalene.

Decolorising Carbons

These are made in granular form or as powders. One form of granular carbon possesses about three to four times the decolorising power of animal charcoal. Another type, of harder quality but less power when compared with animal charcoal, gives the following comparison:—

It possesses less power than animal char in taking out up to 50 per cent. of the colour of a raw sugar solution. It possesses equal power to animal char in taking out up to 75 per cent. When used for a finisher for extracting say the final 25 per cent. of the colour, it possesses about five times the power of animal charcoal. In general, these carbons are inferior for taking out heavy colours, but possess many times the power for taking out light colours, as compared with animal char. It would appear that where possible an economic use could be found for treating sugar and similar solutions, first by animal char for extracting heavy colours, and using these granulated carbons as a finisher, for which purpose they are superior to animal char.

Finely ground carbons are made in a number of qualities. The lowest quality is equal to most of the imported foreign carbons. A second grade is a very high-quality carbon, having roughly twice the decolorising power of the lowest quality, and is very suitable for glycerin, oils and fats. There is another carbon about equal to the second quality, but only of use for oils and fats.

A special, very powerful carbon which is only available in limited quantities has about three times the decolorising power of the lowest quality. A further special carbon, also available in very limited quantities, is the most powerful known decolorising carbon for taking out final traces of colour; it surpasses any other quality of carbon.

It cannot be said that the above exhaust the qualities available, for constant research is being carried out on uses to which these substances may be put, and the possibilities are by no means yet exhausted.

Strange to say, the absorbent and decolorising powers do not seem to have any direct relationship; this may only be due to the difficulty in arranging a comparative test, absorption being usually measured by taking the time that a given carbon will hold back a given vapour and permit none to pass, whereas in decolorisation the percentage of colour removed is determined, and this involves a condition of equilibrium.

Absorptive and Decolorising Power

It would appear that the absorbent and decolorising power depend upon the dimensions of the minute pores that the carbon possesses, and these dimensions evidently vary, depending on the way in which the carbon is made.

Professor Williams in his recent paper describes the pores in silica gel as being probably long wedge-shaped capillaries. This explanation of a material in which the pores are formed by slow drying and by the application of heat from the exterior seems an excellent one. In carbon the porosity is produced first by slow evolution of the primary volatile matter, which no doubt produces or forms similar tapered capillaries as the substance contracts. The final evolution of the residual volatiles, however, does not cause a contraction, and it might be assumed that the secondary capillaries are parallel and will vary in dimensions and number depending upon the shrinkage the carbon first undergoes in its primary treatment.

The final activation by slow oxidation is an action upon the surfaces of these capillaries, leaving them in a lace-like formation presenting an enormous surface.

Assuming the above explanation to be the true one, then there is evidence to show that :—

1 High vapour absorption is associated with small primary capillaries.

2 High decolorising power is associated with larger primary capillaries.

3 Too great a development of the primary capillaries reduces the value of the carbon for both purposes.

Generally speaking, the highest absorption carbon possesses low decolorising power when measured by standard laboratory decolorising tests, and this applies equally to coconut and other shell charcoal on the other hand, a high decolorising carbon possesses fair absorption powers for vapours.

There is an enormous field open for absorbent materials, particularly for solvent recovery. There are undoubtedly many works in this country to-day where recovery of the solvent wasted would pay for the installation of plant to recover it in one year's work.

It is not generally appreciated that, for benzol recovery at coke ovens, in most works the use of carbon following the present oil washers would result in the recovery of a further half gallon of oil per ton of coal.

ISOTOPES

Dr. Aston announced in last week's *Nature* the results of further work on isotopes. He confirms the existence of an isotope of iron of mass 54. Strontium has two isotopes of masses 88 and 86. Barium is a simple element of mass 138; lanthanum is a simple element of mass 139; praseodymium is probably simple and has a mass of 141, neodymium gives an indistinct band 142 to 150 suggesting several isotopes and erbium seems to contain isotopes from 164 to 176.

It is interesting to find that the elements whose atomic numbers are 57 and 59 are simple and their masses differ by two units only. The isotopes which have odd atomic numbers have nearly always isotopes whose masses are all odd numbers; lithium, boron and nitrogen are the exceptions. In almost every case there is an isotope which differs from an isotope of the adjacent odd numbered element by four units. The rare earths in this respect also seem to be nonconformists. There is hardly yet absolutely conclusive evidence to prove whether there are two concurrent lines of elements, the odd and the even, differing from each other by four units at least or one line with a difference of two units at least. Dr. Aston will some day clear up this point. For the convenience of our readers we append a list of the isotopes now known, mainly

taken from Dr. Cranston's book on "The Structure of Matter."

Element	At. number	At. weight	Masses of isotopes in order of intensity of spectral lines
H	1	1·008	1·008

Hg	80	200·6	(197—200) 202, 204

The isotopes of the first thirty-nine elements are now known; the next three are zirconium, niobium and molybdenum: Dr. Aston has more than once tried to record their isotopes but, so far, without success. The next element, whose atomic number is 43, has not been discovered. A number of isotopes of lead, bismuth, radium, thorium and uranium have been identified but there may be other isotopes of these elements of whose existence we are as yet ignorant. It will be interesting when Dr. Aston investigates the isotopes of lead, a metal which occupies a prominent position in the history of isotopy.

ASCARITE

An Absorbent used in the determination of Carbon in Steel by the direct combustion method

By JAMES B. STETSER

During the progress of the world war the enormous expansion of the steel industry of the United States caused a great increase in the amount of analytical work to be done in the laboratories of the various steel plants of that country. This increase was caused not only by enlarged tonnage, but also by more rigid specification both physically and chemically for the steel produced for the allied armies. While the work was increased, there was an actual decrease in the number of qualified laboratory men, due to the great need for chemists in the various wartime chemical industries. It became necessary under these circumstances, not only to increase the accuracy of the tests in order to meet specifications, but also to simplify methods to such a degree that the test could be run accurately by partially-trained men.

It will be easily understood then why it became necessary for the writer, during the early years of the war, while connected with the Penn Seaboard Steel Corporation as metallurgist, to turn his attention to the problem of determining the percentage of carbon in steel, in order to simplify if possible the methods then in use. The Eggertz or colour method, based on the assumption that the carbon in steel when dissolved in dilute nitric acid will give a depth of colour that varies almost directly as the percentage, had to be entirely abandoned. The results obtained by this method on normalised or slowly-cooled steels were reasonably accurate, provided the usual precaution was observed of having the standard and the sample of the same type of steel and the carbon contents approximately equal. However, it took a man with a well-trained eye to use this method even when the carbon content was not over 0·50 per cent. The main difficulty was experienced with the quickly-cooled furnace preliminaries, even when these samples were cooled with compressed air. As the Eggertz method gives a different depth of colour according to the form in which the carbon exists, large errors were found in the results on these furnace tests, due to the fact that the carbon might exist in any form from sorbite to martensite. It proved impossible to cool each test in practice so that the carbon was always in the same form, and hence it was useless to try to provide a standard of like heat-treatment.

Although the combustion method was accurate, it was found necessary to reduce the time taken to run the test, as the method then in use required from ten to twenty-five minutes for each test. When the time necessary to take the test, prepare the sample and report the tests was added to this, it was found that a test could not be reported in less than fifteen minutes from the time it was taken. This interval was too great, as furnace changes took place which might cause a variation from the desired carbon content, and costly delay was sometimes caused by waiting for laboratory results when the furnaces were ready for additions.

Experiments showed that the carbon in a steel sample could be completely burned to carbon dioxide in less than two minutes after it was introduced into the furnace, provided there was free access of oxygen and the furnace temperature was around 950° C. This fact was of little value due to defects in the absorbents then in use. In using the Vanier bulb, the most efficient of the potash bulbs, it was found that at least six minutes were required to wash all carbon dioxide from the train, and even then there was some time lost due to escape of water. Gas could be passed through soda-lime at a rate sufficient for our requirements. This absorbent, however, had other defects—it required phosphorus pentoxide as a dryer which had a tendency to channel and lose water. This was a serious defect as furnace preliminaries were not checked and an error in one of them, if undetected, could cause considerable loss. Also the more efficient soda-limes contained from 5 to 15 per cent. of moisture, which increased the liability of loss. The necessarily heavy weight of absorbent and absorption vessel caused difficulty in weighing as the balance decreased in sensitiveness.

Up to this time, all use of caustic soda or caustic potash as an absorbent had been in the form of a solution in some type of potash bulb. We now experimented to see if these reagents could not be used in some solid form which would probably have little need of an extra dryer. Mixtures with asbestos gave some promise, and a type was finally evolved which needed no drier whatever, and at the same time was marked by the rapidity with which it absorbed carbon dioxide. At the same time, it had another peculiar property that was of considerable value: namely, that the absorbent changed in colour as it became saturated with carbon dioxide. On account of the sharply-defined division of the used and unused portions, it was easy to determine when it was necessary to recharge the absorption bottle. This material, being ideal for our purpose, was put into use in the laboratory using a modified train of our own design, and methods of procedure which had been simplified and standardised.

In estimating the speed with which carbon determinations might be made with this absorbent, standard steels from the U.S. Bureau of Standards were checked in an actual running time of two minutes, but the method adopted allowed a running time of three and one-half minutes, a measured amount of oxygen being used to sweep all carbon dioxide from the train.

When this absorbent had been in use in the laboratory for about one year, an article was published in the *Iron Age* of August 22, 1918, describing our method of determining carbon in the hope that it might prove of interest and value to other steel works chemists. There being numerous requests for the absorbent, it was put on the market under the trade name of "Ascarite," and its use spread so rapidly that it is now used in the majority of the steel laboratories of the United States. Ascarite is distributed by the Arthur H. Thomas Co., West Washington Square, Philadelphia, U.S.A., and supplies can be obtained in Great Britain from the District Chemical Co., Ltd., 1, Fenchurch Avenue, London, E.C. 3.

NOTES FROM WEMBLEY

A collection of apparatus and research chemicals from the University of Birmingham has now been added to the scientific exhibit in the chemical section of the Palace of Industry, in the British Empire Exhibition. Autoclaves, furnaces, turbines and an electric control for vacuum distillation are among the apparatus shown, and the research chemicals include a number of interesting complex salts of cobalt, trimethylstibine, and other specimens illustrating the chemistry of selenium, tellurium, molybdenum and zirconium. Visitors will find many chemicals of topical interest.

Another noteworthy exhibit in the scientific exhibit is to be found in the exhibit of explosives, collected by Sir R. Robertson. This is Dr. B. Flürscheim's exhibit of tetranitroaniline (TNA), which he discovered. Tetranitroaniline is the most powerful solid explosive which has yet been manufactured. The reactions by which the explosive is produced, and those by which it is transformed into other substances, are shown, together with a table giving the relative strengths of TNA and other nitro-compounds.

One is accustomed to the appearance of rubber in the most unexpected places and forms, but a garden made entirely of rubber is a novelty that suggests great possibilities when one considers the "standard" weather. Those who wish to see this "rubber garden," must go to the stand of the North British Rubber Co., Ltd., in the Rubber Section in the Palace of Industry, where they will find an old-world garden with a "crazy" paving path through a lawn, with borders of flowers, with rambler roses and clematis climbing up a loggia, and a fountain, complete with water-lilies and goldfish. Everything—earth, grass, flowers, foliage, crazy paving, fountain, lilies and goldfish—all made of rubber, and very effective, too.

Mention should be made of an artistically-produced booklet illustrating the products of the Washington Chemical Co., Ltd., Washington Station, County Durham, the manufacturers of the well-known "Pattinson's" magnesia. This company, which is not far short of its centenary—it was founded in 1840 by two Fellows of the Royal Society, H. L. Pattinson and R. S. Newall—describes the various kinds of magnesia and magnesium carbonate that it makes in the booklet, which contains illustrations of the firm's works, quarries, laboratory, and provides much interesting, as well as useful information for buyers. It is worth noting that the Washington Chemical Co. invites correspondence regarding new or extended uses for its products in industry or pharmacy.

Those who wander in other parts of the Exhibition should not fail to visit the stand of the Non-Ferrous Metal Trades Joint Committee, on which the Institute of Metals has a remarkable display, illustrating the corrosion of condenser tubes. Diagrams and actual specimens are provided to illustrate each type of corrosion, and the formation of scale. Of great interest is the series of specimens of aluminium treated so as to be resistant to sea-water. A means has now been found of not only making aluminium

resistant to corrosion, but of colouring it. Indeed, it is suggested that coloured aluminium could be used in thin sheets for decorative panelling and even as wallpaper. It should be noted that the Institute of Metals has prepared a booklet admitting visitors to the meetings and library of the Institute during the period of the Exhibition. These booklets can be obtained either from the Institute, 36, Victoria Street, S.W. 1, or from Stand 237, Palace of Engineering.

Agriculture does not lend itself very well to exhibition, but the display provided by the Ministry of Agriculture in the Government Pavilion is worth a lengthy visit. Rothamsted, of course, looms large, with an excellent exhibit designed to illustrate the properties of the soil and some of the methods used for its improvement, but there are also displays relating to plant and animal health and improvement, diseases and pests of animals and plants, farm engineering and agricultural economics. There are kinematograph films and a useful guide-booklet to help the visitor.

FORTHCOMING EVENTS

June 25 BRITISH EMPIRE EXHIBITION. Conferences on "Heredity as the Basis of National and Industrial Efficiency," to be held in Conference Hall 3, at Wembley.

July 9–12 SOCIETY OF CHEMICAL INDUSTRY, Annual General Meeting to be held at Liverpool

July 15. THE INSTITUTE OF CHEMISTRY STUDENTS' ASSOCIATION (LONDON). Visit of Chemical Students to Wembley. At 9.45 a.m. an Inaugural Meeting will be held at University College, Gower Street, W.C. 1, at which the President of the Institute, Prof. G. G. Henderson, LL.D., F.R.S., will take the chair. Mr. W. J. U. Woolcock, C.B.E., General Organiser of the Chemical Section of the Exhibition and President-elect of the Society of Chemical Industry, will explain the objects of the exhibits and the special features of interest. Prof. W. P. Wynne, C.B.E., F.R.S., President of the Chemical Society, hopes to support the speaker at the meeting. The cost of the visit, including return ticket to Wembley, entrance to the Exhibition, and ticket for luncheon, will be 5s. Further information can be obtained from Mr. G. S. W. Marlow, 30, Russell Square, London, W.C. 1, and applications should be made not later than June 23.

Sept 8 to 11. INSTITUTE OF METALS. Annual Autumn Meeting, to be opened at the Institution of Mechanical Engineers, when W. M. Corso, S.B., will deliver the third annual Autumn Lecture. On September 9 the morning will be devoted to reading and discussion of papers, followed by luncheon at the Connaught Rooms, Kingsway, the afternoon to be spent at the British Empire Exhibition. On September 10 further papers will be presented for discussion, the afternoon being devoted to visits to works. A reception will be held in the evening at the National Physical Laboratory, Teddington. A detailed programme will be issued in August.

SOCIETY OF CHEMICAL INDUSTRY

ANNUAL GENERAL MEETING, 1924

PATRON: H.M. THE KING

The Annual General Meeting of the Society of Chemical Industry will be held in the Arts Theatre, The University, Liverpool, on Wednesday, July 9, 1924, at 10.30 a.m.

The following is the Programme :—

Tuesday, July 8, 9.0 p.m. Informal Reception by the President and the Local Committee at the Midland Adelphi Hotel.

Wednesday, July 9, 10.30 a.m. Annual General Meeting in the Arts Theatre, The University, and Presidential Address, "A Neglected Chapter in Organic Chemistry: The Fats." 2.30 p.m. Visit to White Star Liner, "Cedric," and tea on board, by invitation of the White Star Line. 8.30 p.m. Reception and Dance in the Town Hall, by invitation of the Rt. Hon. The Lord Mayor of Liverpool (Arnold Rushton, Esq.).

Thursday, July 10, 9.45 a.m. Messel Memorial Lecture by the Rt. Hon. Viscount Leverhulme, in the Arts Theatre, and presentation to the Lecturer of the Society's Messel Medal for 1924. 11.30 a.m. Visit to the Works of Messrs. Joseph Crosfield and Sons, Ltd., Warrington. Luncheon by invitation of the Directors. Inspection of the Works of Messrs. Joseph Crosfield and Sons, Ltd. Cost of travelling, 5s. 7.30 p.m. Annual Dinner, in the Midland Adelphi Hotel. Tickets, exclusive of Wines, 12s. 6d.

Friday, July 11, 10.0 a.m. Business Session in the Physics Lecture Theatre, The University. 1.0 p.m. Luncheon at the Midland Adelphi Hotel, by invitation of the Chairman and Directors of The United Alkali Co., Ltd., followed by visit to Works of The United Alkali Co., Ltd. Cost of travelling, 3s. 6d. 7.30 p.m. Dinner at Port Sunlight, by invitation of the Chairman and Directors of Messrs. Lever Bros., Ltd. Cost of travelling, 2s. 6d.

Saturday, July 12. About 9.30 a.m. (details later). Visit to Lake Vyrnwy. Inspection of the Liverpool Corporation Waterworks (limited to 150). Luncheon and tea, by invitation of the Water Committee of the Corporation of Liverpool. Arrive Liverpool about 9.30 p.m. Cost, dinner on train included, 25s.

Unofficial Excursions. Tickets to be booked in Liverpool at Reception Room:—Chester, River Dee and Eaton Hall; Isle of Man; Llandudno and Beaumaris (sea); Lake District (two days).

Members intending to attend the meeting are requested to send their applications, accompanied by the appropriate remittance not later than the 28th June to Mr. E. Gabriel Jones, City Laboratories, Mount Pleasant Liverpool, to whom all inquiries relating to private hospitality, railway travelling and other matters connected with the meeting should be addressed.

J. P. LONGSTAFF,
General Secretary

MEETING OF COUNCIL

The monthly meeting of Council was held on June 13, 1924, the President (Dr. E. F. Armstrong, F.R.S.) in the Chair.

It was unanimously resolved to confer the Honorary Membership of the Society on Monsieur Ernest Fourneau, of the Pasteur Institute, Paris, and on Monsieur Armand Solvay, President of the Société Solvay et Cie, Brussels.

The President reported that he had been elected Chairman of the Committee appointed by the Federal Council to carry through the Scheme for obtaining a Central House for the various Chemical Societies.

The Accounts and Balance Sheet for 1923, and the Annual Report of Council were approved. The Treasurer pointed out that during the first five months of 1924 a considerable reduction has been effected in the cost of printing and publishing the *Journal* by the introduction of certain economies.

A cordial invitation was received from the Yorkshire Section to hold the Annual General Meeting in Leeds in July, 1925, and it was unanimously agreed to recommend its acceptance to the Annual Meeting.

Reports of various Committees were submitted and 18 members were elected:—Home 15; Overseas 3.

The arrangements for holding the Autumn Dinner of the Society in London were remitted to the House Committee, and the Committee was given executive powers during the vacation.

The next meeting of Council will be held on Wednesday, July 9, at 10 a.m., in the University, Liverpool.

LIST OF MEMBERS ELECTED, June 13, 1924

Allibone, Bernard C., 109, Sunderland Road, Forest Hill, London, S.E. 23. Chemist.

Anderson, James T., 6, Sycamore Grove, Rugby. Analytical Chemist.

Byrne, George T., 21, Alexandra Road, Ansdell, Lytham, Lancs. Professor of Chemistry.

Griffin, Kenneth M., High Street, Auckland, New Zealand. Government Analyst.

Guthrie, Francis C., Lyndhurst, Mossley Hill, Liverpool. Lecturer in Chemistry.

Guttin, Henry, Titusville, Poughkeepsie, New York, U.S.A. Engineer Counsellor.

Hamilton, Charles H., c/o Messrs Wm. Gossage and Sons, Ltd., Widnes. Chairman.

Holliday, George C., Reydon Hall, Wanstead, London, E. 11. Research Chemist.

Keyworth, Charles M., 39, Rosslyn Street, Aigburth, Liverpool. Chemist.

Lescher, T. Edward, 56, Hanover Street, Liverpool. Managing Director.

Maurer, Edward, St. Thomas' Laboratories, Commercial Road, Portsmouth. Research Chemist.

Merchant, Douglas J., 64, Newbridge Road, Bath. Chemist.

Moors, Albert E., "Brookside," Norman Road, Runcorn. Tanner.

O'Sullivan, Daniel J., c/o Public Analyst, Eglinton Street, Cork. Analytical Chemist.

Read, Douglas E., Box 161, East Angus, Que., Canada. Chemist.

Roberts, Miss Muriel, 36, The Judges Drive, Newsham Park, Liverpool. Analyst.

Towers, John S., Laurel Bank, Woolton Road, Wavertree, Liverpool. Laboratory Furnisher.

Turner, Charles F., 27, Elsmere Avenue, Aigburth Road, Liverpool. Analyst.

CHEMICAL SOCIETY

At an ordinary scientific meeting held on Thursday, June 5, the President announced that an extraordinary general meeting would be held on Thursday, June 19, at 7.45 p.m., and would be followed by an ordinary scientific meeting.

Mr. H. Burgess read the following paper :—

Studies in dynamic isomerism. Part XVI. Mutarotation of beryllium benzoylcamphor. Formation of an additive compound with chloroform. The optical activity of beryllium. (With T. M. Lowry.)

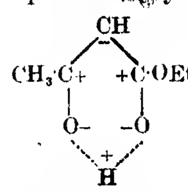
(*a*) BERYLLIUM benzoylcamphor, $Be(C_{17}H_{19}O_2)_2$ is a colourless crystalline compound melting at 208°. It is remarkable for showing a slow mutarotation, *e.g.*, from 490° to 443° in benzene. The material can be recovered, and after slow crystallisation exhibits the same high initial rotation and subsequent mutarotation as before. The mutarotation can be catalysed by piperidine, but benzoic acid produces also a permanent decomposition. Measurements of solubility, with and without a catalyst, have given the proportion of the initial form in the final equilibrium-mixture in alcohol and in acetone, whilst from concurrent measurements of the optical rotatory power of the saturated solutions the specific rotation of the unknown labile isomeride in these two solvents has been deduced.

(*b*) Beryllium benzoylcamphor unites with two molecular proportions of chloroform to produce the additive compound $Be(C_{17}H_{19}O_2)_2,2CHCl_3$. This crystallises in prisms instead of in discs; but these gradually become opaque by loss of chloroform. When dissolved in benzene or acetone, the additive compound gives at once the *final* rotatory power of beryllium benzoylcamphor in these solvents; but when dissolved in chloroform the last stages of a rapid mutarotation were observed. The free beryllium compound also exhibits a very rapid mutarotation in chloroform, which appears therefore to have a definite catalytic action on the mutarotation.

(*c*) The cause of the mutarotation is not certain, but it is attributed provisionally to the opening out and closing again of the ring-system of a co-ordinated complex of the cyclic type.

Dr. N. V. Sidgwick remarked that the isolation of a compound with chloroform was unusual, although the solubility of these substances was usually greater in chloroform than in benzene.

Prof. C. K. Ingold recalled that failure to isolate two enolic forms (and their metallic derivatives) of ethyl acetoacetate: $CH_3{\cdot}C(OH):CH{\cdot}CO_2Et$ and $CH_3{\cdot}CO{\cdot}CH:C(OH)OEt$, had previously been quoted by Prof. Lowry as proof of the cyclic polar structure:



although the speaker had pointed out that due consideration had not been given to such success

in the cases of ethyl formylphenylacetate and ethyl *s*-diacetylsuccinate. The new evidence for the existence of two series of metallic derivatives in the case of benzoylcamphor was at variance with this untenable hypothesis; isolation of the unstable free enol of benzoylcamphor would decide the point. Further, it seemed that the co-ordination of the metal required proof; solubility in organic solvents was inconclusive evidence since many salts of the simple fatty acids, *e.g.*, copper butyrate, are freely soluble in organic media.

Prof. Lowry said that an unexpected discovery was that metallic derivatives exhibit mutarotation at all: chloroform stopped the rotation of nitrocamphor but was a catalyst of the mutarotation of the metallic derivative. It must be admitted that the co-ordination compounds of beryllium are tetrahedral, and the evidence showed beryllium benzoylcamphor to be a co-ordination compound. His own explanation of the phenomenon was fundamentally that of Prof. Morgan in the case of basic beryllium acetate. The speaker had obtained new evidence, based mainly on absorption spectra, that the copper salts of the higher fatty acids are probably co-ordinated.

Prof. Lowry then read the following paper:—

Studies of valency. Part IV. Absorption spectra of camphor, benzylidenecamphor and camphorquinone. (With Miss H. S. French.)

(*a*) A SOLUTION of camphor in alcohol shows a band at log $\epsilon=1{\cdot}57$, λ 2880 A.U. In benzylidenecamphor the band is moved to log $\epsilon=4{\cdot}32$, but the wave-length is practically constant at 2900 A.U. In camphorquinone the wave-length is altered to 4650 A.U., but the intensity remains practically constant at log $\epsilon=1{\cdot}46$.

(*b*) The bearing of these observations on the origin of visible colour, and on the theory of rotatory dispersion is discussed.

Mr. J. E. Purvis said that the use of the iron arc for the study of absorption spectra is defective on account of its irregularity, whereas the radiations of the spark are regular and constant within the usual allotted time. Benzaldehyde in alcoholic solution gives bands at λ 2850 and λ 2456; the camphor band is at λ 2880 (Lowry) or λ 2850 (Purvis). The benzylidenecamphor band at λ 2900, with its greater intensity, might therefore be caused by the overlapping of the bands still present in the two different systems; no mention had been made of the fate of the benzaldehyde band at λ 2456. Again, the camphor band shows no resolution into a series of narrower vapour bands; the benzaldehyde band at λ 2850 is resolved into a number of finer bands when in the vaporous condition, but the band at λ 2456 undergoes no such resolution. The camphorquinone solution band also splits up into a number of narrower bands in the vaporous condition. Mr. Purvis suggested the desirability of a comparison of the vapour of benzylidenecamphor with those of benzaldehyde, camphor, and camphorquinone, and in fact an extension of such comparisons to all observations of absorption spectra.

Replying, Prof. Lowry expressed the opinion that the source of light was, in these experiments, of no consequence.

Dr. J. Kenyon then described:

The resolution of α-terpineol (with A. T. Fuller).

dl-α-TERPINEOL has been resolved into its optically active components by the fractional crystallisation of its hydrogen phthalic ester with four different alkaloids. The α-terpinyl hydrogen phthalates thus obtained show $[\alpha]_D \pm 36{\cdot}7°$ in ethyl alcoholic solution, and on hydrolysis with alcoholic potash give optically active α-terpineols of $[\alpha]_D^{20} \pm 100{\cdot}5°$ in the homogeneous state.

d-Terpinyl hydrogen phthalate, when heated with aqueous potash, gives *d*-limonene of $[\alpha]_D^{20}+107{\cdot}8°$. The formate, acetate, propionate, *n*-butyrate and *n*-valerate of the active terpineols have been prepared. The rotatory powers of these esters lie on a smooth curve except in the case of the propionate which shows a slight exaltation; the latter effect is enhanced when the rotatory powers are determined in solvents.

Dr. R. H. Pickard congratulated the authors on the first complete resolution of a tertiary alcohol in bulk, and on the successful application of the phthalic ester method in such a case. The use of four different alkaloids practically excluded the possibility of formation of mixed crystals.

Prof. C. S. Gibson, also extending his congratulations, said that in similar work he had experienced difficulty with mixed crystal formation. It was specially interesting that resolution was obtained equally well by brucine and strychnine.

The twelfth Faraday Lecture was delivered on Thursday, June 12, at the Royal Institution by Prof. R. A. Millikan, of the California Institute of Technology, Pasadena. In introducing the lecturer the President, Prof. W. P. Wynne, observed that by a happy chance the first lecture since 1914 was to be delivered by a citizen of the great nation across the Atlantic; a man whose researches on the electron were as highly appreciated here as in his own country.

Prof. Millikan commenced his discourse by saying that he would present an account of the present status of the "discrete" and "continuous" points of view in the consideration of electrical and optical phenomena and would endeavour clearly to differentiate between fact and fancy. After a reference to Maxwell's repudiation of the atomic view of electricity, he began with the assertion that the electron is no longer an hypothesis, and described his "oil-drop" experiments to prove that an electric charge can be varied only by definite stages. The dimensions of positive and negative electrons might for practical purposes be ignored, although it was an unexplained fact that the former has a mass 1845 times as great as that of the latter. Among the "agreed facts, free from fancy," were mentioned the concentration of positive electricity in the nucleus of an atom, and its equality in amount to the negative electricity; the variation of the unneutralised electrons by unit stages from 1 to 92 (tribute being paid to Moseley's

work in this direction); the significance of atomic weight and atomic number; radiation of the outer electrons by falling from an outer to an inner energy-level; and the confirmation of the Planck-Einstein-Bohr law of radiation.

Remarking that these facts were proof enough of the amazing advances made during the past fifteen years, the lecturer admitted, amid laughter, that knowledge was now desirable of "how the electrons spend their leisure time when not radiating: whether they should be regarded (as by the physicist) as active, or (as by the chemist) as loafing around on the corners of dry goods boxes." While not entirely admitting their applicability, he mentioned the assumed validity of the electromagnetic laws, and the existence of localised valencies, as representing the chief opposition to the former view, and then proceeded to describe the quantitative successes of the orbit theory, with incidental reference to his own experimental work on "stripped atoms," whereby the precise effect of the two close-in electrons in screening the other electrons could be computed. If the test of truth was the accounting for old relationships and the successful prediction of new ones, then the orbit theory must be accepted, and the stationary electron theory rejected. The electronic and sub-atomic world was being revealed to the modern physicist with consistency and definiteness; the theory, like that of the atom itself, would in its evolution admit of addition, but not of subtraction.

Maxwell's dielectric theory was then subjected to criticism, rather from the point of view of the situation created by modern discoveries regarding electromagnetic wave phenomena than that of its original foundations.

Although Einstein's equation had met with general acceptance, the idea of light quanta was still viewed with suspicion; Prof. Millikan, however, described new experiments which had produced unambiguous evidence for the reality of the Compton effect, so that not merely the equation but also the Einstein conception is having new successes. In fact, atomic conceptions in the field of ether waves seem at the moment to hold the master-key to progress.

The President then invited Prof. Millikan's acceptance of the Faraday Medal, the highest honour which the Society could bestow in appreciation of his wonderful discoveries.

A vote of thanks was proposed by Prof. F. G. Donnan, who said that the Faraday Lectureship had enabled them to bring to London many of the greatest men in the scientific world, among whom the present lecturer held a very high place. The speaker's own experience was that among the great things for which the United States of America were justly renowned, the greatest was their science; there had always been great American scientists, but the last seven years were specially marked by their "red-hot" enthusiasm.

Sir Oliver Lodge, seconding, congratulated the Society on being able to hand the Faraday Medal, in Michael Faraday's own Lecture Theatre, to a worthy successor, and testified to the brilliant scientific results being achieved in America. Personally, he agreed with Prof. Millikan in accepting the orbital atom, but he was not surprised that chemists were inclined to "shy" at it.

The vote having been carried with acclamation, Prof. Millikan said that he was deeply touched by the heartiness of the welcome accorded to him; the medal and its associations were to him an exceedingly precious honour. Moreover, the medal was presented in the Royal Institution, where Faraday worked, by people of that stock whom he regarded with the affection which exists between children and their parents, and he assured them that in his country the sentiment was widespread and controlling. It was not, after all, so much a question of where one lived; the development of science diminished the importance of geographical position. Nevertheless, the future of the Anglo-Saxon race was one with the future of England.

A vote of thanks to the members and managers of the Royal Institution terminated the proceedings.

THE SOCIETY OF DYERS AND COLOURISTS

The annual dinner was held in the Hotel Victoria, Northumberland Avenue, London, on June 11. The guests included Dr. E. F. Armstrong, F.R.S., president of the Society of Chemical Industry; Dr. C. Doree, Chairman of the London Section of the society; Mr. W. J. U. Woolcock, of the Association of British Chemical Manufacturers; Mr. W. W. Leuchars, Renter Warden of the Dyers' Company, and Sir Max Muspratt, Chairman of the Council of the Association of British Chemical Manufacturers.

Dr. E. F. Armstrong, in proposing the toast of the Society of Dyers and Colourists, said they had succeeded in spite of the politician in producing a big proportion of the colours used in Britain and in building up an industry of which they were very proud. The President (Mr. S. J. Pentecost), in responding said the past ten years had justified the optimism of those who desired to see Britain once again produce the colours needed for her textile industry. It was the duty of the Government of the day to foster and maintain the dyestuffs industry of the country and to encourage research in the coal-tar industry in every way. Mr. L. J. Hunt, Prime Warden of the Dyers' Company, in proposing "Allied Industries," said his company was the oldest connected with the industry, their records going back to the 13th century. Mr. H. J. Holroyd, Chairman of the National Federation of Dyers and Cleaners, responded.

Dr. H. A. Wilson, professor of physics in the Rice Institute, Houston, Texas, U.S.A., has been appointed to the chair of natural philosophy in the University of Glasgow. Born in Yorkshire, Prof. Wilson studied at Leeds, Berlin and Cambridge (where he was Clerk Maxwell student in the Cavendish Laboratory) and became professor of physics in King's College London, in 1901. In 1909, he occupied the chair of physics at McGill University, Montreal, and in 1912 he went to the Rice Institute.

CORRESPONDENCE

A NEW HOT-AIR BATH

Sir,—Perhaps some of your readers will be interested in the hot-air bath here described. When distilling or heating inflammable liquids in a flask, the flask may crack and the liquid spill over the bench and cause a serious fire.

The heater here described is so formed as to minimise this risk of fire, and to enable one to recover a large proportion of the contents of the flask.

Further, when subjecting a valuable substance (*e.g.*, Menthylamine) to steam distillation, should the flask break, the heater will retain the aqueous mixture which can be poured into another flask. The small hole, X, is for pouring off any liquid not got away through holes D. X is plugged with asbestos fibre when heater is in use.

The heater is made up of: (i) a cone, B, well made and watertight, with eight ⅜ in. holes, D, punched as near as practicable to the common seam of A, B

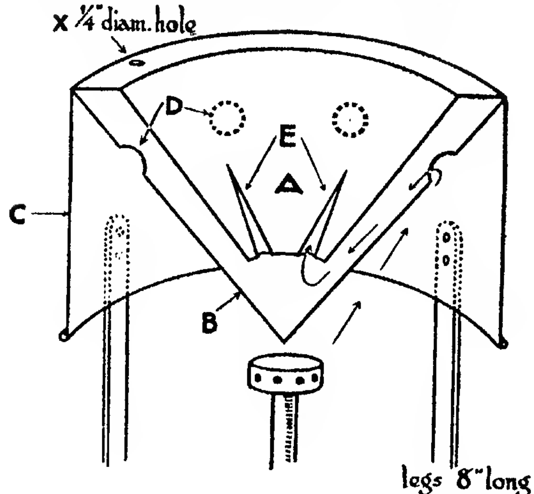


Fig. 1

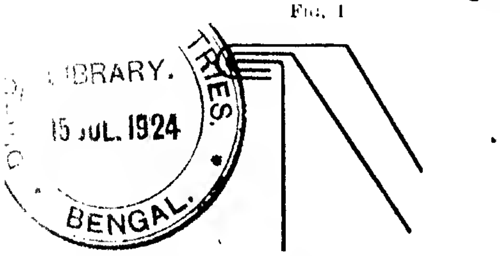

Fig. 2

and C: (ii) a cone, A, with the apex cut away, and having half-a-dozen serrations, E; (iii) a cylinder, C, of depth equal to depth of cone B.

A, B and C are lap-jointed, as shown in Fig. 2. The flask sits snug in the cone A, and is subject to heating by hot-air and conduction, eliminating trouble due to local heating.

Dimensions are: Cone B, 8 in. diam. × 4 in. deep. The diagrams will explain the rest. Three legs can be rivetted to the cylinder walls (C), which will then make the heater self-contained, to be used in conjunction with a Bunsen burner. The heater is very satisfactory for temperatures up to 140° C.—I am, Sir, etc.,

G. A. Collinson

Organic Laboratory,
The University, Leeds

WHAT A MEMBER THINKS

Dear Mr. Editor,—Your issue of March 21 has just reached here. Now, about your articles written for the non-technical reader. Quite frankly, the technical man who is so absorbed in his technicalities that he cannot convert his knowledge into common-sense language is one of the chief enemies of science. It should be possible to state scientific truth in such language and in such a manner that an ordinary well-educated non-technical person should be able to comprehend it. I do not necessarily say use it. I, for one, am glad to tell you that your articles on elementary things are very welcome indeed to a busy man down under. Many thanks for your articles on Evaporation; they are just what I want.—I am, Sir, etc.,

Harry Williams

CHEMISTRY IN THE 20th CENTURY

Sir,—I have read the review of "Chemistry in the Twentieth Century," and your comment thereon in the current number of your *Journal*. I am not sure whether the Reviewer "damns with faint praise," but I, and many other teachers, will feel inclined to damn the publisher, and whoever else is responsible for the preposterous price at which the book is published. Fifteen shillings for VIII+281 pages!! A book of this kind surely should be sold at a price low enough to bring it within the reach of schoolboys and schoolgirls. A really interesting book of this type is simply invaluable to the teacher. Cannot something be done to bring such a story of real scientific achievement into the hands of those to whom it would be useful?—I am, Sir, etc.,

Teacher

COULD NOT A CHEMOR PRACTISE CHEMISTRY?

Sir,—I am not willing that the Canadian-born suggestion to coin the word "Chemor" as a designation for members of the chemical profession should be dismissed with so shallow a witticism as concludes the letter of Mr. John S. Bousfield of Cambridge in the issue of April 25.

Mr. Bousfield asks whether I would say, "I am a chemor and I practice chemorry." Certainly not. Mr. Bousfield might provide himself an idle hour's amusement by applying his surely original principle of word formation to the designation of the occupations of the actor, auditor, author, doctor, pastor, proctor, procurator, tutor, etc. To add zest to his pursuit I challenge him to produce a single parallel to the form he creates to ridicule.

So far as I am aware no one has felt the need of a new word for our occupation. "Chemistry" serves the purpose quite well. But the actual need of a word to distinguish the "qualified chemist" from the man who revels in the various designations of apothecary, chemist, chimist, dispensator, dispenser, dispensing chemist, druggist, druggister, drugster, pharmaceutist and pharmacist is the very occasion for all our discussion. To Mr. Bousfield's suggestion of "Chartered Chemist" it may be objected that (1) if institute diplomas are "charters," so also are the diplomas or licences of the pharmacists; (2) this designation occupies seventeen letter spaces, against six for "chemor"; (3) its inevitable abbreviation to "C.C." diminishing to "c.c.," may furnish more justifiable grounds for mirth than even the curious word "chemorry," which my learned colleague "wishes on" me.—I am, Sir, etc., J. F. Snell

Macdonald College, Que.

THE INTERNATIONAL UNION OF CHEMISTRY

Sir,—This last week, on opening the just issued Part II. of Dr. Böeseken's "Configuration of the Saccharides," my eye was caught by the following footnote on page 1: "The Conference on organic chemical nomenclature, held at Cambridge in June, 1923, decided that substances which until then had been called glucosides, should in future take the general name *glucide*."

The reference is to the International Union I assume, at which I was present. There was no such Conference, nor was the subject ever before the meeting. I learn, however, on enquiry, that a committee discussed matters of nomenclature *in camera*, and I suppose this is the "Conference" to which reference is made. No committee should have plenary powers to deal with such problems, nor should such decisions be taken at the meeting at which they are proposed. The Geneva Conference should be a warning to us. To abolish a term so time-honoured, useful and significant, and substitute one that is meaningless would be absurd.

The Union is about to meet in Copenhagen. Thus far it has acquired no legislative authority. The question to be decided in the near future is, whether it can be made acceptable to chemists and popular; whether, and to what extent it shall be authoritative. Probably most will say: "The less the better; let its position be, in the main, to bring men together from different nations, so that they may learn to know one another and form some common opinion of the needs and possibilities in chemistry, so that they may co-operate in giving value to our science in the different countries represented." The body must be organised upon more simple lines, and its aims and object carefully defined. At present far too much is being attempted and too many questions which are not of international importance are being considered. It is unfortunate that the beginning made last year at Cambridge, when several monographs in which important issues were discussed, were presented, is not to be followed up this year. There is no agreement between chemists upon matters of general theory, so that we are little short of empirics in far too many of our dealings. We greatly need t discuss these. At present, not only is the represen tion of this or that country more or less a matter chance, but the committees appointed are in no w sufficiently representative of the subjects considere I have enough experience of International Organis tions to know how difficult it is to make them effe tive, even when the task is a simple one. Certainl it will only be by making the task of the Internation Union a simple one that it can be made effective the way many of us desire it should be. Fraterni will not be encouraged in any body which seeks compel—so until more united in our outlook, we sha do well to confine ourselves mainly to the task of promoting International understanding and amity. I am, Sir, etc., Henry E. Armstrong

THE HISTORY OF THE GAS PROCESS

Sir,—We note, in the number of *Chemistry and Industry* for June 13, 1924 (p. 614) your remarks as to the evolution of "accepted scientific facts," in which you refer more especially to the history of the gas process. In reference thereto you mention the contribution of Mr. D. Brownlie (*Chemistry and Industry*, June 6, p. 601). "a correspondent who has evidently been at great pains to authenticate his facts." Brownlie states: "Murdoch described this installation in the most lucid and detailed manner before the Royal Society *of Arts* in 1808 and the account can of course be read in *their journal* whilst at the same time he was awarded for this paper the Society's Rumford Gold Medal." And when the historical development of the gas process is referred to, this is the statement commonly made. What are the facts? Murdock read his paper before the Royal Society on February 25, 1808, was awarded the Rumford medal of the *Royal Society* (consisting of a *gold medal and silver replica*) in 1806, and "the account can of course be read in the Philosophical Transactions of the Society." I am, Sir, etc., D. Chandler

PERSONAL AND OTHER ITEMS

Mr. J. E. P. Wagstaff, M.A., has been appointed professor of physics in the University of Durham and not in the University of Leeds, as was wrongly stated in the issue of June 13. The Cavendish professor of physics in the University of Leeds is, of course, Prof. R. Whiddington.

Dr. R. F. Ruttan, Macdonald professor of chemistry in McGill University, Montreal, has been appointed Dean of the Faculty of Graduate Studies. Dr. G. Stafford Whitby has been appointed to a chair of organic chemistry, and Dr. O. Maass to a chair of physical chemistry in the same University. It is understood that Prof. Whitby will visit England during the summer.

Mr. G. M. Bennett, M.A., M.Sc., late fellow of St. John's College, Cambridge has been appointed lecturer in organic chemistry in the University of Sheffield.

On June 13, the gold medal of the Royal Astronomical Society was presented to Prof. A. S. Eddington, F.R.S., for, amongst other reasons, his work on the internal constitution of a star, and for his expositions of relativity.

Mr. B. T. Bush has become president of the Synthetic Organic Chemical Manufacturers' Association of the United States.

Mr. W. M. Corse, who is to deliver the Autumn Lecture of the Institute of Metals on September 8, is a member of the U. S. National Research Council.

Sir Max Muspratt, chairman of the United Alkali Co., Ltd., is now back in Liverpool, after spending some time investigating the company's mines in Spain.

We regret to announce that Mr. Charles Lorleberg a director of R. W. Greeff & Co., Ltd., of London, and Manchester, died suddenly from heart failure on June 11.

The Discovery of Benzene

Benzene, the material from which the host of dyestuffs manufactured to-day is primarily derived, was first prepared in the Royal Institution laboratory by Faraday, who announced his discovery to the Royal Society on June 16, 1825. The Managers of the Royal Institution, in association with the Chemical Society, the Society of Chemical Industry, and the Association of British Chemical Manufacturers, have decided to celebrate the event on June 16 next year. The arrangements are in charge of a joint Committee of the four bodies.

Thermal Properties of Methyl Chloride

The Food Investigation Board of the Department of Scientific and Industrial Research has published in Special Report No. 19, by the Engineering Committee of the Board (Pp. 16, Price 1s.), an account of the thermal properties of methyl chloride, by D. N. Shorthose, M.A. The Report is supplementary to the report on ethyl chloride (No. 14), by Prof. C. F. Jenkin. Measurements are given of the specific heat, total heat, saturation specific volumes, latent heat, vapour density, and vapour pressure curve, figures being given both in tables and in charts. The data, though prepared with the object of constructing charts for the use of refrigerating engineers, will be found of interest to chemists, especially as the methods used in determining the data are described in detail.

Canadian Mineral Resources

The Dominion Department of Mines has sent Mr. W. Malcolm, M.A. (Geological Survey) and Dr. A. W. G. Wilson (Mines Branch) to London. These officers will be available, either at the Canadian Pavilion at Wembley or at the office of the High Commissioner for Canada, Kinnaird House, Pall Mall East, London, S.W. 1, to furnish authoritative information on Canadian mineral resources and on the utilisation of the mineral products found in Canada.

REVIEWS

A Short History of Chemistry. By R. Stern, B.Sc. Pp. viii+149. London: J. M. Dent and Sons, Ltd. 1924. Price 2s. 6d.

Some little light is thrown upon our methods of teaching chemistry in schools by the fact that Miss Stern's book is the first history of chemistry to be written primarily for boys and girls. From personal experience I can vouch for the fact that, until recently, there was no book on the history of chemistry in two of our public schools and one of the largest day schools in the country, in all of which chemistry had been taught for at least twenty-five years. I have no reason to believe that these schools were in any way exceptional, and I have wondered how far Prof. Smithell's recent complaint about the lack of scientific knowledge among the general public, in spite of the intensive work of a generation of science teaching in schools, may have been caused by too great an insistence upon the practical side of science and too little upon its human aspect.

It is indisputable that science has found it difficult to win regard as an essential part in a general education, and that it is still often considered to be a professional and specialist section of the curriculum, even when it is studied by the whole school. Something of this attitude towards science is reflected in the remark of a boy to a predecessor of mine at Clifton: "I didn't know you were writing a book, sir. Is it an intellectual book or a book on chemistry?" I believe that the chief aim of those who teach chemistry in schools should be to instil into the minds of their pupils (and of their colleagues) that chemistry—as typical of science—is primarily a philosophy, a method leading to a definite outlook on life, rather than a craft. That it has features characteristic of the latter, and those, too, of such a kind that only a child whose intelligence is distinctly below the normal can fail to gain some profit from them, is, of course, a great additional advantage, and renders chemistry, when properly taught, an ideal means of education. But it is, so I think, a serious mistake to pay so much attention to technical matter and methods and so little to those essentials which chemistry has in common with the humanities. A formidable protagonist of the heuristic method has remarked that when boys and girls begin the study of chemistry they should be shut up in a laboratory by themselves for a year and left to find out what they can. To my mind it would be equally useful to shut a novice at classics into a library with Homer in Greek and Vergil in Latin. To introduce the element of danger in order to make the parallel complete, one might add translations of Martial and Petronius.

The easiest and most satisfactory way of making chemistry in schools a living thing—for science specialist and unspecialist alike—is the adoption of the historical method. That there are other ways I should be the last to deny, but I know of no other of such general application or production of such good results. Miss Stern may therefore be congratulated on having made a valuable contribution

to the progress of this method, for there can be little doubt that her attractive and inexpensive little book will meet with widespread approval. The weakest part of the book is that dealing with alchemy and iatrochemistry, with which the author has obviously very little acquaintance. It is to be hoped that in the next edition these twelve pages will be rewritten. For the rest of the book the reviewer has nothing but praise. Miss Stern's style is simple and straightforward; her matter is interesting, and her perception of vital facts is sure. Those for whom the book is intended will enjoy reading it, and those chemists who have left their schooldays far behind may spend a pleasant evening with it refreshing their memories of giants of the past.

E. J. HOLMYARD

THE TEXTILE FIBERS: THEIR PHYSICAL, MICROSCOPICAL AND CHEMICAL PROPERTIES. By J. MERRITT MATTHEWS, Ph.D. Pp. xviii + 1053. Fourth Edition, revised and enlarged. New York: John Wiley and Sons, Inc., and London: Chapman and Hall, Ltd., 1924. Price 50s.

The author mentions that so much new matter has appeared on textile fibres of recent years that he has found it necessary to re-write and re-arrange the book. He has done this in a very thorough manner, in fact in a manner which has also distinguished his other books. Attempts have been made to find omissions of references to important researches, but little success has been achieved, and the importance of such an admission is realised when one considers the enormous amount of work which is being turned out by the staffs of research institutions and by other workers. It may be argued, in fact, that the research institutes are creating a new science relating to textile fibres and publications of the nature of the one under review will have to realise that position. Whether it is better to consider research in periods and give, say, ten yearly digests of different branches of research, or to review the whole field in one volume, is open for argument, but certain it is that the author, by adding new matter to his previous compilation, and then rewriting the whole, has produced an excellent book, and one which should be on the shelves of all engaged in the treatment of textile fibres. Illustrations are given of apparatus and machinery and a number of fibre micrographs.

The information given is in some cases so complete that one wonders whether one is reading a book dealing generally with textile fibres or with some special branch of the treatment of those fibres. For instance, the chapter on the mercerising of cotton is large enough for a book on finishing, and it is difficult to reconcile a full discussion of the recovery of caustic soda from mercerising liquors with inclusion in such a volume. A sense of proportion seems to be lacking, but the inclusion of such matter is for the good from the point of view of the purchaser. Artificial silks are thoroughly treated, but flax hardly receives attention commensurate with its importance. Perhaps this is, however, because the literature relating to it is scant and not always reliable. All the fibres used in commerce from asbestos to nettle fibre are considered. The analysis of textile fibres and yarns and tests for distinguishing different fibres are treated at length, but the matter, on the testing of yarns and fabrics for strength, is split up into different sections of the book. A critical comparison of the different methods of testing would be useful in the light of modern work on this subject. In discussing cellulose the author dwells at length on the chemical constitution, a matter which is out of place in a volume of this kind, but he gives little space to recent work on the fundamental natures of the celluloses contained in all vegetable fibres. One school of chemists regards the celluloses of all vegetable matters as identical, and this is an important point with which the author could have dealt.

Omissions in the bibliography are noticed; in one case a book mentioned in the text is not included.

S. H. HIGGINS

REPORT

REPORT ON THE ECONOMIC, FINANCIAL, AND INDUSTRIAL CONDITIONS OF THE NETHERLANDS, TO FEBRUARY, 1924. By R. V. LAMING. Department of Overseas Trade. Pp. 69. H.M. Stationery Office, 1924. Price 2s.

The occupation of the Rhine area by the French has had a big detrimental effect on the economic situation of the Netherlands, principally on account of the dislocation of transport.

In agriculture the sugar crop was disappointing, a yield of 210,000 t. on the year's working being expected, against 250,000 t. in 1922, on 20 per cent. less acreage. The potato crop was also reduced, though good in quality.

The production of coal in 1923 amounted to 4·85 million t., and of lignite, 41,000 t.; prospecting has shown seven new coal-beds suitable for exploitation. The production of salt amounted to 26,393 t., against 25,810 t. in 1922.

Dutch industries appear to have got over the worst of the depression. The textile industries are still in difficulties, but margarine and incandescent lamp manufacturers are prospering. Labour difficulties have had to be faced all round, principally on account of the stringent legislation regulating employment. The cessation of supplies of raw materials from the Ruhr was also felt severely at first, but has been countered, with some benefit to British trade.

In 1923 the value of imports was 2009 mill. fl. (£1 = fl. 12·10 at par; 11·38½ to 11·90 in 1923), and of exports 1303 mill. fl., imports having decreased by about 19 mill. fl. from 1922, and exports increased by 82 mill. fl. One of the principal reasons for the increased exports was the demand for Dutch coal, whilst exports of earth, clay, and sand were also important. Some of the principal items of export other than foodstuffs were coal, 2,034,557 t.; coke, 561,718 t.; incandescent lamps, 4678 t.; linseed oil, 52,761 t.; artificial silk yarns, 1754 t.; plantation rubber, 6809 t.

PARLIAMENTARY NEWS

Australian Zinc Concentrates

Mr. A. V. Alexander informed Sir F. Wise that 1,298,489 tons of zinc concentrates, including slime concentrates, had been delivered to the British Government under the contract with the Zinc Producers' Association Proprietary, Ltd. Regarding the prospects there was very little change in the situation.—(June 16.)

COMPANY NEWS

W. J. BUSH & CO., LTD.

The gross profit for 1923 was £249,885 and the net profit to £48,109, to which £18,197 brought forward must be added. A final dividend of 7 per cent. is recommended on the ordinary shares, making 10 per cent. for the year and leaving a carry forward of £35,056.

BOOTS PURE DRUG CO., LTD.

The net profit for the year ended March 31 last was £628,620. The preference and preferred dividends absorb £96,750, leaving £531,870. Dividends for the whole year have been paid on the ordinary shares totalling 36 per cent., less tax, requiring £360,000, the balance remaining being £171,870. The amount brought forward was £138,682, and out of the total of £310,552 it is proposed to transfer £100,000 to reserve, carrying forward £210,552. At March 31, 1923, the reserve amounted to £1,303,989, since when £900,000 has been capitalised, leaving £403,989, which is increased to £503,989 by the addition now proposed. The profit and loss account shows that before computation of the net profit £56,412 has been set aside for repairs, renewals, etc., £41,437 for taxation, and £35,291 for depreciation, whilst £20,000 is allocated for staff pension fund, making a total allocation to that fund of £40,000. The balance sheet totals £3,982,838.

DUNLOP RUBBER CO., LTD.

At the annual general meeting it was not found possible to proceed with the scheme of capital reconstruction which had been put forward by the board, owing to the opposition of the Parent Tyre Co. In consequence, representatives of the various classes of shareholders were appointed to consider the scheme with the board.

LANTARO NITRATE CO., LTD.

A second interim dividend on account for the year 1924 is announced of 5 per cent., or 5s. pre share, less tax, payable on July 8.

The New Brunswick Power Commission has surveyed and proposes developing the Grand Falls, on the St. John River. The falls are located in a well settled district, and the electricity can be easily distributed within small radius of the plant. The initial development is placed at 50,000 h.p.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.
Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

All grades of boric acid have been reduced by £3 per ton as from June 11. Borax prices are unchanged. Prices generally remain steady.

Acetic Acid, 40% tech. ..	£23 10s. per ton.
Acid, Boric, Commercial	
Cryst.	£45 per ton.
Powder	£47 per ton.
Acid Hydrochloric ..	3s. 6d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw. ..	£21 10s.—£27 per ton makers' works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder ..	Spot £11 d/d., Contract £10 d/d. 4 ton lots.
Bisulphite of Lime ..	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride ..	£5 17s. 6d. per ton d/d.
Methylated Spirit 64 o.p.—	
Industrial	3s. 1d.—3s. 5d. per gallon, according to quantity.
Mineralised	4s. 2d.—4s. 6d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate ..	5¼d. per lb.
Potass. Chlorate	3d.—4d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£3 10s. per ton d/d.
Soda Caustic, solid ..	Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98% ..	£24 per ton.
Sod. Bicarbonate ..	£10 10s. per ton, carr. paid.
Sod. Bichromate	4¼d. per lb.
Sod. Bisulphite Powder	
60/62%	£18—£19 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96% ..	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £14 10s. per ton d/d.
Sod. Sulphide cryst. ..	£9 per ton d/d.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	5¾d.—1s. 4d. per lb., according to quality.

Crimson .. .. 1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow 1s. 11d. per lb.
Barytes .. .. .. £3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide .. 3s. 9d. per lb.
Carbon Bisulphide .. £24—£26 per ton according to quantity.
Carbon Black .. 6¼d. 6¾d. per lb. Market firmer.
Carbon Tetrachloride .. £56 per ton, drums free.
Chromium Oxide, green .. 1s. 3d. per lb.
Indiarubber Substitutes, White and Dark } 4¾d.—6¼d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black .. .. 45s. per cwt., barrels free. Dearer.
Lead Hyposulphite .. 7½d. per lb.
Lithopone, 30% .. .. £22 10s. per ton.
Mineral Rubber "Rubpron" .. .. .. £15 10s. per ton f.o.r. London.
Sulphur .. .. .. £10—£12 per ton, according to quality.
Sulphur Chloride .. 3d. per lb., carboys extra.
Thiocarbanilide .. .. 2s. 9d. per lb.
Vermilion, pale or deep .. 4s. 10d. per lb. Easier.
Zinc Sulphide .. .. 7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

All prices keep fairly stable, but there is room for improvement in business.

Acetate of Lime—
Brown .. .. .. £14 10s. per ton d/d. Demand active.
Grey .. .. .. £19—£20 per ton. Fair demand.
Liquor .. .. .. 9d. per gall. 32° Tw.
Charcoal .. .. .. £7 5s.—£9 per ton, according to grade and locality. Demand below normal.
Iron Liquor .. .. 1s. 7d. per gall. 32° Tw.
1s. 2d. ,, ,, 24° Tw.
Red Liquor .. .. 10d.—1s. per gall. 14/15° Tw.
Wood Creosote .. .. 2s. 7d. per gall. Unrefined.
Wood Naphtha—
Miscible .. .. 5s per gall. 60% O.P. Market dull.
Solvent .. .. 5s 6d. per gall 40% O.P. Fairly good demand.
Wood Tar .. .. £5 per ton.
Brown Sugar of Lead .. £46 per ton.

TAR PRODUCTS

Acid Carbolic—
Crystals .. .. 6½d.—7d. per lb. Demand quiet.
Crude 60's .. .. 1s. 9d.—1s. 10d. per gall. Market flat. Only odd lots being offered.
Acid Cresylic, 97/99 .. 2s 1d.—2s. 2d. per gall. Demand still good. Market firm.
Pale 95% .. .. 1s. 10d.—1s. 11d. per gall. Steady demand.
Dark .. .. .. 1s. 8d.—1s. 11d. per gall. Steady business.
Anthracene Paste 40% .. 4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—
Strained .. .. 9½d. per gall. Very quiet.
Unstrained .. .. 8½d.—9d. per gall.
Benzole—
Crude 65's .. .. 10½d. 1s. per gall. ex works in tank wagons.
Standard Motor .. 1s. 4½d. 1s. 6d. per gall. ex works in tank wagons.
Pure .. .. 1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.

Toluole—90% .. .. 1s. 5½d. per gall.
Pure .. .. 1s. 10d.—2s. per gall.
Xylol coml. .. .. 2s. 3d. per gall.
Pure .. .. 3s. 3d. per gall.
Creosote—
Cresylic 20/24% .. 9d.—9½d. per gall. Few inquiries.
Middle Oil .. } 7d.—9d. per gall. according to
Heavy .. .. } grade and district. Demand
Standard Specification } not so strong.
Naphtha—
Solvent 90/160 .. 1s. 4d.—1s. 5d. Market steady.
Solvent 90/190 .. 1s. 1d.—1s. 2d. Fair business passing.
Naphthalene Crude
Drained Creosote Salts £6—£6 10s. Demand falling off.
Whizzed or hot pressed £9—£12 per ton. Little business.
Naphthalene—
Crystals and Flaked .. £16—£17 per ton.
Pitch, medium soft .. 52s. 6d.—57s. 6d. per ton. Market steadier. Few inquiries for forward delivery. Very little business for prompt.
Pyridine—90/160 .. 21s. 6d.—22s. per gall. Demand well maintained.
Heavy .. 12s.—12s. 6d. More business passing.

INTERMEDIATES AND DYES

Business in dyestuffs has been fairly good and seems again to be on the upward move.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% .. 1s. 6d. per lb.
Acid H. .. .. .. 4s. 4d. per lb. 100% basis d/d
Acid Naphthionic .. 2s. 4d. per lb. 100% basis d/d
Acid Neville and Winther 5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech. .. 1s. 2d.—1s. 3d. per lb. Steady
Acid Sulphanilic .. .. 10d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd. .. .. .. 1s. per lb. d/d.
Aniline Oil .. .. 7¾d.—8¼d. per lb. naked at works.
Aniline Salts .. .. 7¾d.—9d. per lb. naked at works
Antimony Pentachloride 1s. per lb. d/d.
Benzidine Base .. .. 4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95% .. 1s. 3d. per lb.
p-Chlorphenol .. .. 4s. 3d. per lb. d/d.
p-Chloraniline .. .. 3s. per lb. 100% basis.
o-Cresol 19/31° C. .. 4¾d.—5¼d. per lb. Demand moderate.
m-Cresol 98/100% .. 2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C. .. 2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline .. .. 3s. per lb.
Dichloraniline S. Acid .. 2s. 6d. per lb. 100% basis.
p-Dichlorbenzol .. .. £75 per ton.
Diethylaniline .. .. 5s. per lb. d/d., packages extra, returnable.
Dimethylaniline .. .. 2s. 4d. per lb. d/d. Drums extra
Dinitrobenzene .. .. 9d. per lb. naked at works.
Dinitrochlorbenzol .. £84 10s. per ton d/d.
Dinitrotoluene—48/50° C. 8d.—9d. per lb. naked at works
66/68° C. 1s. 2d. per lb. naked at works
Diphenylamine .. .. 3s. per lb. d/d
Monochlorbenzol .. £63 per ton.
β-Naphthol .. .. 1s. 1d. per lb. d/d.
α-Naphthylamine .. 1s. 4½d. per lb. d/d.
β-Naphthylamine .. 4s. per lb. d/d.
m-Nitraniline .. .. 5s. 3d. per lb. d/d.
p-Nitraniline .. .. 2s. 4d. per lb. d/d.
Nitrobenzene .. .. 5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol .. 2s. per lb. 100% basis d/d.

Nitronaphthalene	..	11¾d. per lb. d/d.
p-Nitrophenol	..	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol		4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	..	4s. 2d. per lb. d/d.
p-Phenylene Diamine	..	10s. 3d. per lb. 100% basis d/d.
R. Salt	..	2s. 6d. per lb. 100% basis d/d.
Sodium Naphthionate	..	2s. 5d. per lb. 100% basis d/d.
o-Toluidine	..	8½d. per lb.
p-Toluidine	..	3s. 6d. per lb. naked at works.
m-Toluylene Diamine	..	4s. 6d per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The demand is steady for the small quantities required for home consumption, but export inquiry for larger bulk is wanting.

Acid, Acetic 80% B.P.	..	£48 per ton.
Acid, Acetyl Salicyclic	..	3s. 3d.—3s. 5d. per lb. Market rather weak, but fair demand.
Acid, Benzoic B.P.	..	3s. 9d. per lb. Larger supplies available.
Acid, Boric B.P.	..	Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain. Prices reduced by £3 per ton.
Acid, Camphoric	..	19s.—21s. per lb.
Acid, Citric	..	1s. 6½d. per lb., less 5% for ton lots. Market extremely firm. Upward tendency.
Acid, Gallic	..	3s. per lb. for pure crystal. Market firmer.
Acid, Pyrogallic, Cryst.	..	7s. per lb. for 1 cwt. lots. Market firm; increasing demand.
Acid, Salicylic	..	Prices quoted from 2s. per lb. down to 1s. 8d. for ton lots. Market weak.
Acid, Tannic B.P.	..	3s. per lb. Market quiet.
Acid, Tartaric	..	1s. 1½d.—1s. 2d. per lb. less 5%. Better tone but not yet very active. Cheap offers of second hand parcels of foreign acid. Higher prices expected in view of firmness of raw materials.
Amidol	..	9s. per lb. d/d.
Acetanilide	..	2s. 3d. per lb. for quantity. Demand slow. Prices shaded to secure large orders.
Amidopyrin	..	13s. 6d. per lb. Neglected. Stocks low.
Ammon. Benzoate	..	3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.		£37 per ton.
Atropine Sulphate	..	12s. 6d. per oz. for English make.
Barbitone	..	15s. 6d. per lb. Quiet market.
Benzonaphthol	..	5s. 6d. per lb. Small inquiry.
Bismuth Salts	..	A steady market. Prices according to quantity:
Bismuth Carbonate	..	12s. 9d.—14s. 9d. per lb.
„ Citrate	..	11s. 4d.—13s. 4d. „
„ Salicylate	..	10s. 2d.—12s. 2d. „
„ Subnitrate	..	10s. 9d.—12s. 9d. „
Borax B.P.	..	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides—	..	Fluctuating market. Continental prices decidedly firmer.
Potassium	..	11d. per lb.
Sodium	..	1s. „
Ammonium	..	1s. 1d. per lb.
Calcium Lactate	..	Demand active. Good English make can be had from 1s. 7d. to 2s. 6d. per lb.
Chloral Hydrate	..	3s. 10d. per lb., duty paid. Advanced. Higher prices are quoted from the Continent.
Chloroform	..	2s. per lb. for cwt. lots. Very steady.
Creosote Carbonate	..	6s. 6d. per lb. Little demand.
Formaldehyde	..	£57 per ton, *ex works*. English make.
Glycerophosphates—		Fair business passing.
Calcium, soluble and citrate free	..	7s. per lb.
Iron	..	8s. 9d. per lb.
Magnesium	..	9s. per lb.
Potassium, 50%	..	3s. 6d. per lb.
Sodium, 50%	..	2s. 6d. „
Guaiacol Carbonate	..	11s. 3d. per lb. for cwt. lots. Export orders small.
Hexamine	..	3s. 6d. per lb. for English make. Market dull.
Homatropine Hydrobromide	..	30s. per oz.
Hydrastine hydrochlor	..	English make offered at 120s. per oz.
Hydroquinone	..	4s. 3d. per lb. in cwt. lots. Foreign make.
Hypophosphites—		
Calcium	..	3s. 6d. per lb., for 28-lb. lots.
Potassium	..	4s. 1d. per lb.
Sodium	..	4s. „
Iron. Ammon. Citrate B.P.		2s. 1d.—2s. 5d. per lb., according to quantity.
Magnesium Carbonate—		
Light Commercial	..	£36 per ton net.
Magnesium Oxide—		
Light Commercial	..	£75 per ton, less 2½%.
Heavy Commercial	..	£26 per ton, less 2½%.
Heavy Pure	..	1s. 6d.—2s. per lb., according to quantity. Steady market.
Menthol—		
A.B.R. recryst. B.P.	..	55s. per lb. Weaker.
Synthetic	..	26s.—35s. per lb., according to quantity. English make. Steady demand.
Mercurials	..	Market firm.
Red oxide	..	5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	..	3s. 6d.—3s. 7d. „
White precip.	..	4s. 7d.—4s. 8d. „
Calomel	..	3s. 11d.—4s. „
Methyl Salicylate	..	2s. 1d.—2s. 6d. per lb. for carboys. Not much demand.
Metol	..	11s. per lb. British make.
Paraformaldehyde	..	3s. per lb.
Paraldehyde	..	1s. 4d.—1s. 6d. per lb. in free bottles and cases. Better demand.
Phenacetin	..	6s. per lb. Very slow.
Phenazone	..	7s. 3d. per lb. for cwt. lots. Quiet.
Phenolphthalein	..	6s. 6d. per lb. Weaker.
Potass. Bitartrate—99/100% (Cream of Tartar)	..	88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate	..	1s. 10d.—2s. 2d. per lb. Dearer.
Potass. Iodide	..	16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Metabisulphite	..	7½d. per lb., 1-cwt. kegs included.
Quinine Sulphate	..	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	..	5s. 6d. per lb.
Saccharin	..	63s. per lb., in 50-lb. lots.
Salol	..	3s. 6d. per lb. Very quiet.
Silver proteinate	..	9s. 6d. per lb.
Sod. Benzoate, B.P.	..	2s. 9d. per lb. In steady demand for good qualities.
Sod. Citrate, B.P.C., 1923		1s. 11d.—2s. 2d. per lb., according to quantity. Firm in common with other citrates.

Sod. Hyposulphite—		
Photographic ..	.. £13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.	
Sod. Metabisulphite cryst.	37s 6d.—40s. per cwt. nett cash, according to quantity.	
Sod. Nitroprusside	.. 16s. per lb. Less for quantity.	
Sod. Potass. Tartrate (Rochelle Salt)	.. 77s. 6d.—81s. 6d. per cwt., according to quantity. Market quiet.	
Sod. Salicylate ..	.. Market easier. Powder 2s. 3d.—2s. 6d. per lb. Crystal at 2s. 5d.—2s. 8d. per lb. Flake 2s. 9d.—2s. 10d. per lb.	
Sod. Sulphide		
Pure recryst. ..	.. 10d.—1s. 2d. per lb., according to quantity.	
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.	
Thymol	.. 15s.—15s. 6d. per lb. for good white crystal from ajowan seed. Very firm and scarce.	

PERFUMERY CHEMICALS

Acetophenone ..	.. 12s. 6d. per lb.	
Aubepine .	. 11s. 6d ,,	
Amyl Acetate .	.. 2s 9d. ,,	
Amyl Butyrate .	.. 6s. 9d. ,,	
Amyl Salicylate .	. 3s 3d ,,	
Anethol (M.P. 21 22 C.)	4s. 6d ,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. ,,	Cheaper
Benzyl Alcohol free from Chlorine ..	.. 3s ,,	Cheaper.
Benzaldehyde free from Chlorine .	.. 3s. 6d. ,,	
Benzyl Benzoate	.. 3s 6d. ,,	
Cinnamic Aldehyde .. Natural ..	. 15s 6d. ,,	
Coumarin ..	.. 20s. ,,	
Citronellol ..	.. 16s. ,,	
Citral .. .	.. 10s ,,	
Ethyl Cinnamate	.. 15s ,,	
Ethyl Phthalate ..	. 3s. 3d. ,,	
Eugenol	.. 10s 6d. ..	Cheaper.
Geraniol (Palmarosa)	.. 35s. ,,	
Geraniol	.. 11s. 18s. 6d per lb.	
Heliotropine ..	.. 6s 6d. per lb.	
Iso Eugenol ..	.. 15s. 9d. ,,	
Linalol ex Bois de Rose	28s. 6d. ,,	
Linalyl Acetate .	.. 28s. 6d. ,,	
Methyl Anthranilate	.. 9s. 6d. ,,	
Methyl Benzoate	.. 6s. ,,	
Musk Ambrette ..	.. 48s. 6d. ,,	
Musk Xylol ..	.. 16s. 6d. ,,	
Nerolin	.. 4s. ,,	
Phenyl Ethyl Acetate	.. 12s. 6d. ,,	
Phenyl Ethyl Alcohol	.. 16s. ,,	
Rhodinol . ..	. 57s. 6d. ,,	
Safrol . ..	.. 1s. 10d. ,,	
Terpineol . ..	.. 2s. 9d. ,,	
Vanillin	.. 25s. 3d.—26s. 6d. per lb.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A. .. .	.. 15s. 6d. per lb.	
Anise Oil	.. 2s 10d. per lb.	Cheaper.
Bergamot Oil ..	.. 19s 6d. per lb	Dearer.
Bourbon Geranium Oil	.. 36s. 6d. ,,	
Camphor Oil ..	.. 75s. per cwt.	
Cananga Oil Java	.. 10s. 6d. per lb.	
Cinnamon Oil, Leaf	.. 6½d. per oz.	
Cassia Oil, 80/85%	.. 9s. 3d. per lb.	
Citronella Oil—		
Java 85/90% ..	.. 6s. per lb.	
Ceylon	.. 3s. 9d. per lb.	
Clove Oil	.. 7s. 6d. per lb.	
Eucalyptus Oil 70/75%	.. 2s. 2d. per lb.	
Lavender Oil—		
French 38/40% Esters	27s. 6d. per lb.	
Lemon Oil ..	.. 3s. 2d. per lb.	
Lemongrass Oil	.. 3d. per oz.	
Orange Oil, Sweet	.. 13s. 9d. per lb.	
Otto of Rose Oil—		
Bulgarian ..	.. 27s. 6d. per oz.	
Anatolian ..	.. 23s. 6d. per oz.	
Palma Rosa Oil	.. 19s. per lb.	
Peppermint Oil—		
Wayne County	.. 20s. 9d. per lb.	Weaker.
Japanese ..	.. 15s. 6d. per lb.	Weaker.
Petigrain Oil ..	.. 10s. per lb.	
Sandal Wood Oil—		
Mysore	.. 26s. 6d. per lb.	
Australian ..	.. 21s. per lb.	

PATENT LIST

The dates given in this list are, in the case of Applications for Patents, those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before August 11, they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court Chancery Lane, London, W.C. 2, on June 26th.

I.—Application

Gelder. Grinding and pulverising machines. 13,593 June 4.

I.—Complete Specifications Accepted

73 (1923). Mewes. Separating and utilising the constituents of gases. (216,545.)

5838 (1923). Reavell, and Kestner Evaporator and Engineering Co. Rotary drying-machines. (216,577.)

5976 (1923). Kucher. Refrigeration. (195,943.)

6293 (1923). Thompson and Henshalwood. *See* VI.

12,122 (1923). Bennis. Furnaces. (216,666.)

12,394 (1923). Thomson and Nisbet. Apparatus for filtering dust-laden gases. (216,675.)

16,565 (1923). Schmies, and Deutsche Luftfilter-Bauges. Removal of constituents from gases. (216,708.)

24,037 (1923). Fasting. Rotary kilns. (205,796.)

27,876 (1923). Lodge-Cottrell, Ltd. (Metallbank und Metallurgische Ges. Akt.-Ges.). Apparatus for the electrical precipitation of suspended particles from gaseous fluids. (216,789.)

31,348 (1923). Kucher. Refrigeration. (208,547.)

II.—Applications

Banner. Preparation of emulsions of oil and water. 13,546. June 4.

Frey. Fuel compact, and manufacture of same. 13,79[illegible] June 5. (U.S., 5.6.23.)

Heyl. Distillation of oil shale etc. 13,891. June 6.

Humphreys and Glasgow, Ltd., and Stelfox. Manufacture of gas. 13,616. June 4.

Jackson (Koppers Co.). Eliminating hydrogen sulphide etc. from fuel gases and air. 13,781. June 5.

Nicklin. 13,694. *See* III.

Soc. Anon. des Pétroles Houilles et Dérivés. Treatment of hydrocarbons. 13,626. June 4. (Fr., 11.11.23.)

Soc. Anon. des Pétroles Houilles et Dérivés. Production of coke etc. 13,731. June 5. (Fr., 28.11.23.)

II.—Complete Specifications Accepted

5868 (1923). Jackson (Koppers Co.). Coking ret[illegible] oven batteries. (216,579.)

9505 (1923). Soc. Anon. de Construction de Fours à Coke Simplex. Gasifying coal, lignite, and bituminous fuel. (196,599.)
13,966 (1923). Beaudequin. Manufacture of artificial coal or coal-like substances. (216,691.)
16,565 (1923). Schmios, and Deutsche Luftfilter-Bauges. See I.
23,231 (1923). Johnson (Badische Anilin und Soda Fabrik). Manufacture of active carbon. (216,761.)

III.—Applications

Nicklin. Recovery of creosote oil from crude coal gas. 13,694. June 4.
Soc. Anon. des Pétroles Houilles et Dérivés. 13,626. See II.

IV.—Application

Eberlein. 13,907. *See* XIII.

IV.—Complete Specifications Accepted

8837 (1923). Ransford (Cassella und Co.). Manufacture of alkylated and aralkylated derivatives of vat-dyestuffs. (216,622.)
13,120 (1923). Durand und Huguenin Akt.-Ges. Manufacture of mordant dyestuffs. (197,940.)

V.—Applications

Calico Printers' Association, Ltd., and Dawson. 13,788. See VI.
Hartogs. Spinning viscose. 13,898. June 6 (Holland, 25.7.23).
Hartogs. Spinning viscose. 13,899. June 6.
Hartogs. Manufacture of viscose solutions. 13,900. June 6.
Kirschbraun. Paper manufacture. 13,886. June 6.
Rinman. Dry distillation of alkalized waste liquor from soda-cellulose manufacture. 13,798. June 5.

V.—Complete Specifications Accepted

26,467 (1923). Bocken. Obtaining fibres from the leaves of agaves etc. (216,777.)
31,362 (1923). Vams. Continuous chlorination of raw cellulose. (208,551.)

VI.—Applications

Cadgene. Printing of textile fabrics. 13,553. June 4 (U.S., 15.2.24).
Calico Printers' Association, Ltd., and Dawson. Scouring and bleaching textile fibres etc. 13,788. June 5.
Johnson (Badische Anilin- und Soda-Fabrik). Treatment of cellulose esters for dyeing. 13,503. June 2.
Lepine. Desulphurizing, bleaching, etc. fibres etc. 13,820. June 6.
Livsey, and Worrall, Ltd. Method of obtaining effects on textile fabrics. 13,729. June 5.

VI.—Complete Specifications Accepted

2833 (1923). Mitchell and Wordsworth. Dyeing and like machines. (216,556.)
6293 (1923). Thompson and Henshulwood. Dye vats, tanks, and like receptacles. (216,595.)
6683 (1923). Lord. Apparatus for treating hanks of yarn with liquids. (216,598.)

VII.—Applications

Blumenfeld and Weizmann. Titanium compounds. 13,446. June 2.
Jackson (Koppers Co.). 13,781. *See* II.
Soc. Anon. d'Eclairage et d'Applications Electriques. Extracting krypton and xenon from the atmosphere. 13,925. June 6. (Fr., 29.6.23.)

VII.—Complete Specifications Accepted

12,660 (1923). Akt. Dansk Svovlsyre- & Superphosphat Fabrik, and Dansk Akt. Siemens-Schuckert. Automatic regulation of the supply of oxidising agents, nitric acid, nitrate solution, or others in the manufacture of sulphuric acid. (199,004.)
19,229 (1923). Michael. Processes for making potassium nitrate. (208,114.)

VIII.—Applications

Eggimann and Perea. Translucent materials. 13,674. June 4. (Fr., 12.6.23.)
Tams. Semi-porcelain body for pottery. 13,711. June 5.

VIII.—Complete Specification Accepted

4897 (1924). Michaelis. Manufacture of high-grade plate glass. (212,250.)

IX.—Applications

Keay. Cementing pulp stones. 13,478. June 2.
Keay. Abrasive cement. 13,479. June 2.
Peace. Manufacture and hardening of concrete products. 13,534. June 4.

IX.—Complete Specification Accepted

6967 (1923). Meadows. Compositions for making or waterproofing roads. (216,602.)

X.—Applications

Aciéries Réunies de Burbach-Eich-Dudelange Soc. Anon. Treatment of molten slag, metals, etc. 13,697. June 4. (Luxembourg, 16.10.23.)
Ashanti Goldfields Corporation, Ltd., and Rhodes. Ore-roasting furnaces. 13,686. June 4.
Chemische Fabrik Griesheim-Elektron, and Beielstein. Recovery of light metals from scrap. 13,939. June 6. (Ger., 20.7.23.)
Helfenstein. Metallurgical etc. hearth furnace. 13,518. June 2.
Vincent. Soldering process, and composition therefor. 13,599. June 4.

X.—Complete Specifications Accepted

5886 (1923). Marks (American Smelting and Refining Co.). Extracting tin from its ores. (216,580.)
14,577 (1923). Ashcroft. Treatment of zinc-lead sulphide ores, mattes, and the like. (216,695.)
24,313 (1923). Billington. Ferrous alloys. (216,766.)

XI.—Application

Pehrson and Prentice. Electric furnaces. 13,508. June 2.

XI.—Complete Specifications Accepted

8334 (1923). Ridoni, and Soc. Talco e Grafiti val Chisone. Manufacture of electrodes from natural graphites. (216,617.)
11,442 (1923). Ziegenberg. Galvanic cells. (216,659.)
22,007 (1923). Metropolitan-Vickers Electrical Co. (Westinghouse Electric and Manufacturing Co.). Electric furnaces. (216,756.)
27,876 (1923). Lodge-Cottrell, Ltd. (Metallbank und Metallurgische Ges. Akt.-Ges.). *See* I.

XII.—Application

Banner. 13,546. *See* II.

XIII.—Applications

Bamber. Manufacture of paints, varnishes, etc. 13,790. June 5.
Eberlein. Production of colour lakes. 13,907. June 6.

XIV.—Application

Bamber. 13,789. *See* XX.

XV.—Application

Bray. Treatment of hides, skins, etc. 13,796. June 5.

XV.—Complete Specification Accepted

91 (1923). Le Petit, Burns, and Blanke. Treatment of hides, skins, etc. (216,546.)

XVI.—Complete Specification Accepted

5746 (1923). Harnist. Manufacture of disinfecting-fertilisers from sulphur or metallic sulphides. (194,289.)

XIX.—Application

Bergeret and Dorignac. Preservation of organic or vegetable substances. 13,868. June 6.

XX.—Applications

Bamber. Manufacture of crude dipentene from crude rubber etc. 13,789. June 5.

Coke and Maxted. Oxidation of derivatives of aromatic hydrocarbons. 13,507. June 2.

Coke and Maxted. Oxidation of alcohols and aldehydes. 13,555. June 4.

Coke and Maxted. Oxidation of toluene. 13,634. June 4.

XX.—Complete Specification Accepted

5958 (1923). Holzverkohlungs-Industrie Akt.-Ges. Manufacture of hexamethylenetetramine. (195,602.)

XXI.—Application

Kodak, Ltd. Photographic reversal processes. 13,595. June 4. (U.S., 5.7.23.)

XXIII.—Application

Roberts. Viscosimeters. 13,734. June 5.

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific number: *Australia:* Silk, (675); Pottery, glassware, (676); hardware, aluminium and enamelled ware, (679); *British India:* Metals, hardware, paint, (680); cable varnish, white enamel, (Director General, India Store Department, Branch No. 10, Belvedere Road, S.E. 1); *Italy:* Silk, (687); *Netherlands:* Leather, (688); stationery, (689); silk, (691); *New Zealand:* Iron, (A.X./1038); hardware, (A.X./1039); *Peru:* Tableware, earthenware, (701); *South Africa:* Steel, (A.X./1047); copper, (A.X./1048) & steel roofing, (A.X./1042); *South Latin America:* Earthenware, (699); *Spain:* Tinplate, (695); silk, (696).

Trade Information

Briquetting is of great importance in that it enables the "smalls" produced in the mining of coal and ore, and the manufacture of coke to be utilised, thereby eliminating loss and the cost of storage or removal. A firm that has specialised in briquetting coal, coke, ore, or cement, potassium cyanide, calcium carbide and many other materials is that of Wm. Johnson and Sons (Leeds), Ltd., Castleton Foundry, Armley, Leeds. The brochure "BM2" devoted to briquetting machinery manufactured by this firm illustrates an interesting variety of standard briquetting plant, such as the "Eggette," or "Ovoid" plant for fuel, and plants for peat, lignite, and ore. In addition, recognising the important part played by moisture in briquetting, Messrs. Johnson have evolved, as the result of forty years' experience, a series of horizontal rotary, multitubular, cascade, spiral, and vertical table dryers, as well as calciners, for drying the materials before briquetting. For each class of material, a special dryer is provided, and every attention is paid to suitability and economy of use. Other plant made at the Castleton Foundry includes pitch crackers, mixers and measurers, disintegrators, vertical heaters or cookers and various types of briquetting plant to suit every need. As an illustration of Messrs. Johnson's experience, it is interesting to note that they have supplied briquetting plant to a number of foreign governments. Amongst other specialities of this firm are mining, cement-making, elevating, conveying, drying and washing plant, crushing and grinding machinery, clay-working and concrete-mixing machinery and many other types of plant. Catalogues illustrating these products can be obtained from Messrs. Johnson and Sons on application, and the firm is glad to submit plans and estimates to deal with any proposition.

The Reproduction of Colour in monochrome by means of photography presents hosts of fascinating problems. Despite the voluminous literature, however, evidence is not wanting that the virtues and limitations of photographic reproductions are imperfectly appreciated. For this reason, a welcome must be given to a booklet on the "Wellington Spectrum Plate," issued by Messrs. Wellington and Ward, Ltd., of Elstree. In plain, clear language, the booklet sets out to show what can and what cannot be expected of a panchromatic plate, and gives notes on development, the use of light and contrast filters, desensitisers and desensitising that are both sound and very much to the point. The Spectrum panchromatic plate, the subject of the booklet, is used for the reproduction of landscapes, coloured objects, pictures and portraiture, and recognition is given to the aid which such a plate can render to the microphotographer in the rendering of minute structures by the inclusion of a list of micro and contrast filters with their respective spectral transmission. A useful booklet that combines interest and instruction.

VOL. 43 NEW SERIES | LONDON, JUNE 27, 1924 | No. 26

EDITORIAL

OUR readers continue to devote their attention to the problem of an accurate designation for the chemist and for his work. We hope that they will succeed to the satisfaction of everyone, but our hopes are not very sanguine. The subject is so vast, the interests so many and varied, and the psychological reactions so deeply seated, that even an approach to unanimity seems remote. It is no cause for regret that opinions on chemical topics are so varied; it is rather a reason for congratulation, for it shows how vital the science, how keen its votaries, how much work still remains to be done. Indeed, it is not an unfair question to ask: What is a chemist? We all know chemists whose work lies, so to speak, within the covers of Roscoe and Schorlemmer or Cohen, but we know of many others who rejoice in the title, but yet never approach chemistry much nearer than physics and mathematics, though by intransigents these may be considered as branches, humble, but necessary, of our science. On more than one occasion chemists have been trounced because they have become, or so style themselves, gas chemists, brewery, metallurgical, water, industrial or pure chemists. What is a chemist, and what, indeed, is chemistry? These are questions that we shall not attempt to answer: States and Sciences alike have their "terre irredente," their unredeemed territories, containing subjects belonging to other States and Sciences, and it passeth the wit of man to find a solution that shall be universally acceptable. The human instinct for classification is irrepressible, so we suppose—indeed, hope—that more of our readers will give their opinions when they feel so disposed.

* * *

We have been wondering, despite the heat and the tempting cool of greenery, how a definition of a "chemist" could be worded. But Prof. Drummond, in the letter which we print in our correspondence columns, raises a far more fundamental question; that of the training of the chemist. It was recently reported that Sir Edward Elgar has been studying chemistry. No doubt he has made great progress, but one may doubt whether he would be asked to referee a paper on stereo-isomerism for the Transactions. Yet the chemist is constantly asked to become expert in harmonies other than his own; and last week Prof. Ellis showed the difficulties that arise when he is expected to become a bacteriologist. It all seems to lead back to the question: What is a chemist, for, obviously, his training would not be a matter of controversy were a stricter definition possible. Knowledge is increasing so rapidly, "labels" are coming into use so profusely, that it is well for Prof. Drummond to remind us that the real function of the university is to educate the student, and to give him a knowledge of the fundamental principles

of science. Specialisation is now a commonplace, but it will be readily admitted that a student who has begun to study the carbohydrates in detail before he has mastered his general organic chemistry would make a very strange chemist. Yet, in effect, the student who graduates in chemistry without having some knowledge of general scientific principles is in a very similar position. The problems of the living cell and its activities pervade the whole of chemistry and but few chemists can avoid some contact with them. To look at the question from a standpoint still more utilitarian, might not biochemical knowledge have been in a very different position to-day had the early workers possessed a sound acquaintance with the technique of the microscope? And even to-day, how many chemists are really familiar with the beauty of microchemical methods? Specialisation is inevitable in a vast domain such as that of chemistry, but at least let us have specialists who will erect their own soaring dream pinnacles from foundations set in that fair champaign which is common to all science

* * *

Some of the common misconceptions about chemists and their work are due, without a doubt, to neglect of the philosophic aspects of chemistry, especially its history. And how fascinating does the science become when it is expounded by means of the historical method. It is surprising that one of the modern psychoanalysts has not yet made a study of the reasoning that led Prout to believe that all heavier atoms are simply aggregations of atoms of hydrogen. How one would like to know how Newton became a "firmly convinced atomist," as Prof. Richards calls him. But how much delving remains to be done before we have accurate records on which to build our histories of chemistry. Mr. Holmyard, whose interesting article on Béguin will be found on another page, has laboured greatly to establish some of the data of chemical history, and future historians will be very grateful to him. If the proposal now before the Senate of the University of London is accepted, we shall enter on a new stage in scientific teaching. In brief, the proposal is to establish post-graduate course of study in the history, principles and methods of science, and an important feature is that all students, whether in chemistry, physics or biology, will be required to study the early history of *all* science, and only later the history of their special branch. Further information will be awaited with much interest. This will hardly satisfy Prof. Drummond, however, as reform seems to be most needed in the early undergraduate stages General scientific principles, and of course their history, should be taught, and when they are taught chemistry will benefit greatly. Misconceptions will have to be cleared away: use of Bentham and Hooker does not make a botanist any more than Mellor's treatise will make a chemist. And it is appropriate, when we are beginning to celebrate the centenary of Lord Kelvin, to quote his declaration that all science is one science and any branch of science that places itself outside the pale of the other branches ceases for the time being to be a science.

ATOMS AND ETHEREAL RADIATIONS

A series of three lectures on "Atoms and Ethereal Radiations" was delivered at University College, London, by Prof. R. A. Millikan on June 16, 17 and 19. The chair was taken by Prof. A. W. Porter.

The first lecture, "Bridging the Gap between X Rays and Light," was largely a description of work done in Millikan's laboratory to get beyond the Schuman region. The method consists of obtaining spark spectra in high vacua. The vacuum is maintained with a battery of mercury diffusion pumps. The spark is obtained from a number of Leyden jars charged from a small transformer. The spectra are analysed with metal gratings. The first gratings were ruled to throw as much energy as possible into the first order; but later some were ruled with special sets of spacings so that the high orders, even up to the tenth, were strong. In 1919 Millikan and Sawyer reached 600A, and their latest limit is 136A. Millikan showed a historic slide made by Schuman reaching 1220A. Lyman's limit is 510A. From the other end of the gap Seigbahn has now reached 18A. The gap is thus about 7 octaves.

The gap no longer exists theoretically, as was shown by Millikan in part of the first and the whole of the second lecture. Because of the simplicity of X-ray spectra, it was natural to try, first of all, to apply the methods by which the K, L and M series are arranged to the new region. The effort was entirely successful. Millikan showed fine Moseley diagrams connecting his strong lines, and some excellent slides indicating the progression of these lines with atomic number, like de Broglie's slides for the X-rays. The high resolution was necessary to pick out the doublets and triplets, and track down the lines corresponding to different stages of ionisation of the atom involved: this was similar to the work done in the visible region by Fowler and Paschen. The regular doublet separation can, in all cases, be accounted for by Sommerfeld's fourth power law. For the irregular doublets the linear progression of wave number difference with atomic number was found. The screening constant of the Moseley equation was calculated, and the progression of this factor and its approach to assigned limits were verified. A definite conclusion is reached that the electrons possess coulomb fields, the electrons in the K shell acting, as a limit, as if situated at the nucleus, the screening effect for any set decreasing with increase of atomic number. The laws of X-ray spectra can thus be applied right into the visible spectrum. There is no gap. But Millikan points out a tremendous difficulty. In X-ray spectral laws the doublet separation is calculated from the change of mass with speed of the electron in an elliptic orbit of equal energy to an alternative circular orbit. In the visible region the separation has been accounted for by assuming some undefined assymmetry, which necessitates an energy difference of the circular orbit with the inclination of its normal to unspecified structured axes, resulting in the introduction of the azimuthal quantum

number. Both assumptions have served us well in obtaining large numbers of numerical agreements. Millikan has proved beyond doubt that they are mutually exclusive. Which we must choose, Millikan leaves open. Our consolation, as he points out, is that we have a check on our postulates.

The last lecture was on the penetrating radiations of the upper atmosphere. Kohlhörster has concluded that there is a radiation in the atmosphere for which the absorption coefficient of water is 0·0025, whilst the hardest rays from Th. D. have a coefficient 0·033. Millikan finds a radiation which is very probably that observed by Kohlhörster. However, he finds that the rays are only slightly harder than the most penetrating γ-rays. Millikan also finds that the rays are of local origin. A heavy snowstorm causes their disappearance, and they are cut down to nearly half by 0·3 inches of lead. Millikan puts forward an explanation that the rays are due to radioactive dust of cosmic origin settling slowly through the atmosphere, the decay being rapid enough to account for the diminishing intensity of the rays approaching the earth's surface.

JEAN BÉGUIN

By E. J. HOLMYARD, M.A., F.I.C.

The Science Library at Clifton College recently acquired a copy of "Les Élémens de Chimie," by Jean Béguin, "reveus, expliquez, et augmentez par Jean Lucas de Roy, Médecin Boleducois," Rouen, MDCXXXXVII. Little seems to be known of Béguin. Kopp and Meyer barely mention him, but a few details are given by the omniscient Ferguson in his wonderful "Bibliotheca Chemica," vol. 1, pp 93-94. "Beguinus," he says, "was a native of Lorraine, and flourished at the beginning of the seventeenth century. After studying chemistry and pharmacy at Sedan (?) he came to Paris, where he made chemical preparations, and opened a school for instruction in chemistry, pharmacy and metallurgy. He also visited foreign countries to see the mines and study mineralogy. His first publication was an edition of the 'Novem Lumen Chymicum' of Sendivogius with a preface, 1608. He had great reputation as a teacher, and was among the first to give practical instruction.

"At the instigation of a pupil, Jeremias Barth, he drew up a small manual entitled 'Tyrocinium Chymicum,' printed in 1610. It was meant for his own students 'to save him the trouble of dictating and them of writing' the methods he demonstrated, and it was not regularly published. A copy having got to Cologne, the tract was at once reprinted in 1611, in a tiny 16mo, much to his disgust, and he was thereby compelled to bring out a revised edition, which was published in 1612. A French translation by the author appeared in the same year. The 'Tyrocinium' afterwards became the most popular text book of its time, for between 1611 and 1669 it passed through some fifty editions. There is a list of these (says Ferguson) in my memoir of Beguinus, read to the Philosophical Society of Glasgow but not yet published. There are two translations into German. The English translation ['Tyrocinium Chymicum': or, Chymical Essays, acquired from the Fountain of Nature and Manual Experience. By John Beguinus, Almoner to the most Christian King of France. London: Printed for Thomas Passenger, at the three Bibles upon London-bridge, 1669] was made by Richard Russell [who is famous for his translation of Geber]."

"The book is merely an outline of certain pharmaceutical preparations, but incidentally there is some general chemistry, and it contains the description for the first time of certain substances, with the discovery of which the author is credited."

A careful study of the "Elémens de Chimie" has led me to place a considerably higher value on the book than that assigned to it by Ferguson, and it is scarcely doubtful that the great Lemery (1645—1715) must have been very much indebted to it. It has therefore seemed desirable to place on record some of its main characteristics, especially in view of the facts that copies are rare and that Béguin has never received his due share of attention.

The present copy is described as the fourth edition —which probably implies the fourth edition of the French translation with Lucas de Roy's commentary. The notes and additions made by the commentator are easily distinguishable from the text as they are printed in italic type. Béguin's object in writing the book was, he tells us, to maintain that the new "chemical" remedies, that is, metallic derivatives and the like, were more agreeable, more efficacious and less dangerous than the old vegetable potions. "Chemistry is an art which teaches how to dissolve the natural mixed bodies, and to coagulate [crystallise or precipitate] them when dissolved, in order to make more agreeable, salubrious and reliable medicaments. The word *Chymie* is Greek, signifying in French the art of making liquids, or to reduce solid bodies to a liquid. It is thus called, *par excellence*, inasmuch as it shows how to dissolve (which is more difficult) and also to coagulate. . . . If it is called the Distillatory Art, this is because distillation is its most beautiful and principal operation."

Chemistry is essentially a practical art, although there are people who are content with theory only, and never give themselves to the elegant operations of this art. The subject-matter of chemistry is the compound body, not as susceptible of motion, which is the province of physics, but in virtue of the fact that it may be dissolved and coagulated. Hence men who hear the name "Alchemist" should not immediately think of one who spends all his time in the transmutation of the metals, and dreams of nothing but the admirable mystery of the Philosophers' Stone.

The vulgar drugs and remedies are often useless and obnoxious, as well as difficult to make and not seldom dangerous in use. The patient, at the smell of some *syrop magistral*, "made by great labour according to some recipe I don't know how many feet long," is often "constraint de se vuider

haut et bas sans autre cérémonie." Chemical remedies have never been known to give rise to these unpleasant symptoms. Having elaborated this point in some 26 pages, Béguin winds up his introductory chapter by asserting that chemical medicines, principally those extracted from metals and minerals, will cure epilepsy, leprosy, gout, quartan fever, dropsy, and several other maladies regarded as incurable, and that with "toute douceur, vitesse et sureté."

The three chemical principles are mercury, sulphur and salt, but it must not be imagined that by a chemical resolution one can extract from all bodies the mercury, salt and sulphur sold in apothecaries' shops. The substances into which animal and vegetable bodies may be split up merely have such a resemblance to mineral mercury, salt and sulphur, having relatively the same differences in their essences, actions and properties, that one is justified in calling them by these names. Philosophers have, indeed, given these three principles many names, some of which are indicated in the following table :—

SALT	SULPHUR	MERCURY
Common salt	Saltpetre	Sal armoniac
Bitter	Sweet	Acid
Body	Soul	Spirit
Matter	Form	Idea
Patient	Agent	Informing and moving
Art	Nature	Intelligence
Sense	Judgment	Understanding
Material	Spiritual	Glorious

[Observe the influence of Paracelsan views.]

In illustration of his thesis, Béguin gives an example, since ocular experience is always better than mere reasoning. "If you heat green wood, first of all there is produced an aqueous vapour which is non-inflammable but which can be converted into water if it is collected. . . . This water is called mercury. Afterwards comes an oleaginous and easily inflammable vapour, which if collected becomes transformed into an oil, and is called sulphur. Finally, there is left in the cinders a dry earthy body, which can be extracted with water, and deliquesces in a cold and moist place. It can be converted into a solid by heat, and is called salt."

It should be noted that none of the three principles is free from more or less admixture with the other two. In addition, during chemical resolution, two other substances are commonly met with, which, however, are not to be regarded as "principles"; they are the *terre damnée* or *tête morte* and the *phlegme insipide*. It is customary to neglect them as they have no medicinal virtues.

In the chapters immediately following, Béguin describes the chief chemical operations and gives a table to show their inter-relationship :—

La Chymie a pour objet le corps mixte, duquel elle enseigne
- La solution, de laquelle y a deux especes
  - Calcination, qui se fait par
    - Corrosion par
      - Amalgamation
      - Precipitation
      - Stratification ou cementation avec laquelle a affinité la commixtion
      - Fumigation
    - Cinefaction
    - Ignition par
      - Reverboration, à laquelle se rapporte l'exsiccation de l'humidité native
  - Extraction qui se considere
    - Generalement quand elle est faite par
      - Ascension qui est
        - Seche, qu'on nomme sublimation.
        - Humide, qu'on nomme distillation.
      - Descension qui est
        - Chaude, ou distillation par descension
        - Froide, qui est double
          - Filtration
          - Deliquescence
      - moyen intermede qui se fait par
        - Digestion, qu'on nomme aussi maceration
        - Putrefaction
        - Circulation à quoi se peut rapporter la fermentation
    - Specialement qui se fait par separation de la teinture des corps par menstruè convenable.
- Coagulation laquelle bien qu'elle se trouve toujours avec les especes de solution, amalgamation, precipitation, sublimation, et distillation, toutesfois elle se fait particulièrement par
  - Exhalation
  - Coction
  - Congelation
  - Fixation

TABLE OF CHEMICAL OPERATIONS, SLIGHTLY ABRIDGED

He then proceeds to describe each of these operations in detail. *Calcination* is the reduction of a body to a calx, and is defined by Geber as the pulverisation of a substance by heat. By the word *calx* chemists mean any very fine powder, made by the dissipation of the humidity which bound its particles together; it is applied principally to minerals. When the powder or calx is rendered impalpable, like extremely fine flour, they call it *alcohol*, a word which they use also to express rectified spirit of wine or *alcohol of wine*. It is interesting to find this late survival of the word alcohol in its general mediæval sense; originally, as is well known, *al-kuhl* was the powdered lead or antimony sulphide used as a cosmetic in the East.

Corrosion is a calcination of the compound by corrosive substances, and is carried out in several ways, principally the following; amalgamation, precipitation, stratification and fumigation. Of these,

precipitation is a corrosion made by acids (aqua fortis, etc.), and is performed by plunging the body into the corrosive liquid. Then, after having been corroded or dissolved, it is reduced to a calx, either by separation of the aqua fortis or otherwise. Here Lucas de Roy adds :—" If after solution of the body the aqua fortis does not quit the calx, chemists are accustomed to add substances which will bring about this separation, viz., either plain water, so that by this means the aqua fortis, having lost its strength, leaves the said calx and allows it to *precipitate, i.e.*, to sink to the bottom ; or they add salt or hot salt water. But according to the diversity of material there is a diversity of separations ; thus to separate silver they place in the solution a sheet of copper, to which the silver calx joins and attaches itself by some occult property."

Sublimation is an extraction of most subtle dry parts, which become elevated by the fire and adhere to the vessel. It is carried out by placing the suitably prepared substance to be sublimed in a pot with a round or flat bottom, until the pot is half full. The latter is then placed in a furnace, and to it is luted an aludel, tall enough to reach above the furnace. On the aludel is fixed an alembic having no spout but provided with a small hole in the middle of the top to allow the humid spirits to escape. Afterwards the apparatus is gradually heated, and when all the humidity has been exhaled (which one recognises when, applying a piece of glass or sheet of well-polished iron to the hole, the vapour can no longer be detected), one stops the hole with luting-clay and increases the fire in order to drive up the dry spirits. Now since, according to Geber, sublimation is an elevation made by the fire of a dry body which adheres to the vessel,[1] it appears how *mal à propos* is the vulgar confusion of sublimation with distillation, and with how little reason distilled waters are called " sublimed waters " by some. Furthermore, it should be remarked that this chemical operation is not a new invention, but that it was known to the ancients. For according to Galen and Dioscorides cadmia is prepared in this fashion, and thence pompholyx and spode.[2]

" Distillation," says Béguin, " is an extraction of the humid parts of a body, which are attenuated and elevated as vapour by means of heat." Further details are given by Lucas de Roy in his note on this section : There are two kinds of distillation, viz., direct and oblique. While the oblique is carried out by ascension only, the direct may be *per descensum* as well. In direct distillation by ascension the vapours condense at the top of the alembic and the liquid falls back into the grooved rim, whence it passes into the tube leading to the receiver. " This resolution of the vapours is greatly improved if one pours cold water all round the alembic and its tube."[3] Direct distillation is related to distillation *par la campane*, by means of which oil of sulphur is prepared [*lit.*, by means of which the oil is extracted from sulphur.]

[1] *Summa perfectionis*, Book II, Part 4, Chap. 3 (Russell's translation, 1678, p. 88) : " Wherefore we say, *Sublimation* is the *Elevation* of a dry thing by *Fire*, with adherency to its Vessel."

[2] Cadmia, pompholyx and spodo are all varieties of impure zinc oxide. Under *spode*, Littré gives Oxyde de zinc obtenu par sublimation en calcinant la tuthie.

[3] For the history of the continuous cooling device in distillation see E. O. von Lippmann's *Beiträge zur Gesch. d. Naturw. und d. Technik*, Berlin, 1923, pp. 127 *et seq.*

Oblique distillation is that in which the spirits are made to emerge from the side of the vessel; it is principally used for the distillation of minerals. The vessel in which it is carried out is called the *retort*.

Filtration consists in passing the liquid through grey paper or through a small piece of cloth, so that the large particles are retained on the filter. Lucas de Roy adds, " There are certain things which need to be squeezed, but that which filters without pressure is clearer, and that which goes through under pressure is more turbid. There are also things which must be filtered more than once in order to clear them. Finally, if they are viscous, sticky and slowly running syrups, they must be heated as well."

Deliquescence is when impure calces, salts and similar liquefiable substances are placed uncovered upon a marble slab or sloping glass, or are hung in a bag in a vaporous air, where they yield their *humour* in a pure state. Nevertheless it sometimes happens that no separation of parts is made by deliquescence ; thus when certain salts are placed in a cellar or some other cold and damp place, the external humidity promptly insinuates itself into them and resolves them into a liquid, which may be collected in a vessel placed below to receive it.

Fermentation, although it does not make such an evident separation of the subtle parts from the gross, is nevertheless a way of extracting a very noble essence. Both liquids and solids may be fermented. Liquids which have the quality of hotness, such as the juice of pears and apples, will ferment spontaneously, but those which are of a cold quality, such as cold expressed juices, require the addition of some foreign substance to advance the ebullition and fermentation. Wine lees, yeast, or salt may be used for this purpose.

The two principal operations in chemistry are solution and coagulation. Various methods of solution have already been described, so that it only remains to speak of coagulation. *Coagulation* is that process by which soft and liquid bodies are rendered solid by privation of their humidity. It is brought about in four ways : (1) by exhalation, in which the humidity of the substance to be coagulated is evaporated ; (2) by decoction, in which liquid substances are reduced to a more solid consistency ; (3) by congelation, as when crystals are produced in cellars by the cold ; (4) by fixation, in which substances which are volatile and fly from the fire are rendered able to withstand the latter. It is carried out by addition of a fixative medicine, or by mixtion, sublimation, or cementation, or otherwise according to the nature of the substance dealt with. . . .

The remaining portion of the first part of the book is taken up with practical details concerning the apparatus of the laboratory. Lucas de Roy's note on cutting glass is of interest :—" Il faut quelquefois eslargir la bouche et entrée principalement des cucurbites, en couppant et comme attestant leur

plus haute partie, d'autant que par la faute des verriers, qui les soufflent, ils finissent en col estroit. Pour faire donc ledit attestement il faut avoir tout prest, et à la main des cercles de fer, attachez à des bastons longs ou manches, l'un desquels esgalement approprié en son interieure superficie à la partie et endroit du verre, qui doit estre couppée, sera mis au feu et rougi. Puis appliqué en le tournant doucement ou luy fera serrer le verre estroitement, et l'ayant osté quelque peu apres, il faut soudainement espancher sur le lieu eschauffé par le cercle quelque goutte de salive ou d'eau froide, et ainsi se coupera le verre. l'eschauffant avec méche d'arquebuse allumée par le bout, ou avec le bout d'une verge de fer rougie, la partie du verre ainsi eschauffée et touchée avec le doigt mouillé se fendra aussi tost, s'allongera et croistra la fente ou fissure en la façon que vous voudrez en movant et advançant peu à peu la méche ou verge, ce qui reüssira plus heureusement, si auparavant vous marquez l'endroit et le lieu à couper avec esmeril ou diamant."

Having explained in the first part the general methods of working, Béguin proceeds in the second to give particulars and details of the various operations He begins by sounding a note of warning against the use of leaden vessels in distillation. "Que les vases où on distille ne soient pas de plomb" for they impress a malignant quality on the liquids which are distilled in them, and render them vomitive, quite apart from the fact that the vessels themselves are corroded. It is a fact, he says, that addition of a drop or two of sulphuric acid to liquids which have been distilled in lead vessels will cause precipitation of *ceruse* [lead sulphate here]. He remarks also that care should be taken that the luting material employed to lute together the various parts of a distillation apparatus yields no vapour on heating, lest the liquid distilled should be infected by a foreign quality.

After more preliminary matter of this kind, Béguin gives practical details for the preparation of particular substances. Of these, many have little interest for us at the present day, but others are of importance. In all the instructions, however, it is easy to recognise the work of a man who always appealed to experiment rather than to authority: a characteristic by no means common at that period. A few of the preparations which are described may be noted here.

Eaux Fortes. "Strong waters," which are also called caustic, parting [separatoires], royal, and "de "Gehenne," are obtained by the action of great heat upon vitriol, saltpetre, sal armoniac, antimony, mercury sublimate, alum, cinnabar, and the like. The most caustic of them is *aqua regia*, which dissolves gold. Ordinary *aqua fortis* is prepared as follows. Take two pounds of dried vitriol and a pound of ordinary saltpetre. Grind or mix them together, then place them in a retort in a reverberatory furnace, and having adapted an ample receiver distil gradually for 20 hours. The *aqua fortis* which has distilled over is then purified by silver. A quarter of it is taken, and a dram of refined silver thrown in. When the latter has dissolved, the solution is poured into the remaining three quarters of the original distillate, which will become as white as milk. Let the precipitate settle, and pour off the clear supernatant liquid, which will now be pure. To make *aqua regia*, dissolve one ounce of sal armoniac, or of dried common salt, in four ounces of *aqua fortis*; it will then dissolve gold. Lucas de Roy adds, "It is called *aqua regia* because it dissolves gold, which is the king of metals. It is also called the *Water of the Two Champions*, because nitre and sal armoniac fight at their first meeting, like two sworn enemies. Sal armoniac is called the *Eagle*, because it carries off the gold as the Eagle carried off Ganymede.

Spirit of Common Salt.—The discovery of hydrochloric acid is often attributed to Glauber (1648), or to the pseudo-Valentine (probably about the beginning of the seventeenth century), but Béguin refers to "spirit of salt" as a substance already well known. "Les artistes ont inventé divers moyens pour tirer l'esprit de sel . . . mais moy, je le tire ainsi." "I take 2 lb. of calcined sea-salt and mix it with 6 lb. of brick dust or red earth or common clay. Then I put it in a large and strong retort, of such a size that a third part remains empty. I next adapt a large receiver, in which I put a pound of distilled water, and afterwards I distil for 30 hours, carefully regulating the fire as in the distillation of spirit of vitriol. Then, after having separated the water and the phlegm, I have left at least 20 ounces of spirit, which it is necessary to rectify." The last part of the description is not free from ambiguity, but it seems clear that he obtained a solution of hydrochloric acid. It is of interest to note that Béguin's method agrees almost word for word with that given in an Arabic MS. of about the same date, and of Syrian origin, preserved in the library of the Vatican.

Spirit of Nitre, which Béguin apparently distinguished from *aqua fortis*, is made in a similar way, viz., by heating a mixture of saltpetre with clay. Lucas de Roy notes that water distils over first, but that when the temperature is raised, deep red spirits (which are called *sang de Salamandre*) make their appearance. To separate the phlegm from the spirit (that is, to concentrate the acid) the crude product must first be heated in the water-bath, which removes most of the phlegm, and then redistilled. Care should be taken, he says, in working with the acid, never to mix it, when concentrated, with alcohol, "de peur que le esprits de vin et de nitre, estans meslez purs, ne viennent à causer quelque inflammation." According to Béguin, nitric acid is a useful medicine for colic, pleurisy, quinsy and the stone.

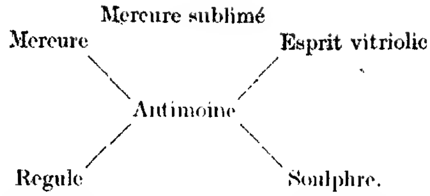
He next describes the preparation of an odoriferous liquid—presumably acetone—by the distillation of lead acetate. It is necessary to lute all the apparatus carefully, "autrement tout le laboratoire se remplira d'une si grande et si suave odeur, que je croy fermement qu'elle surpasse de beaucoup les odeurs de tous les vegetables odiferons mis ensemble."

Poudre Emetic d'Antimoine, ou Mercure de Vic.—Take four ounces of powdered antimony [sulphide] and eight ounces of mercury sublimate. Mix the two together and distil in a retort to which is fitted a

receiver half full of water. If the gummy, butter-like liquid [$SbCl_3$] sticks to the neck of the retort, melt it with a hot coal. When it falls into the water it will be precipitated as a white powder [$SbCl_3+H_2O=SbOCl+2HCl$]. Afterwards heat the retort very strongly and cinnabar will sublime into the neck [$Sb_2S_3+3HgCl_2=2SbCl_3+3HgS$.]. De Roy notes that the white precipitate obtained in the above operation is called *poudre emetique* or powder of Algeroth, "du nom de *Victorius Algerothus*, Médicin et Physicien de Verone, qui luy a donné vogue," or, again, *fleurs de beurre d'antimoine*.

Of especial interest is Béguin's explanation of the formation and constitution of this *poudre emetique*. It is so clear and logical that it appears desirable to quote it *verbatim*: "Je ne me peux toutes-fois assez estonner commes plusieurs doctes, mais peu experts, se sont laissez emporter à une opinion de croire que cette poudre emetique provient du mercure sublimé et non du regule d'Antimoine. Car j'ay assez fait paroistre cy devant à toutes sortes de qualitez de personnes et gens doctes, qui ont honoré mon petit laboratoire de leur presence, et ce par raison fondée sur l'experience (veu que je n'en admets point d'autre en cet art), que la poudre emetique n'est autre chose que le regule d'antimoine [*i.e.*, metallic antimony], dissout et calciné par l'esprit vitriolic du sublimé: duquel l'esprit elle retient d'autant plus ou moins qu'elle est beaucoup ou peu lavée . . . Et par ce que le regule d'antimoine approche plus de la nature metallique que le Mercure, voila pourquoy distilant le mercure sublimé avec l'Antimoine, l'esprit vitriolic du sublimé quitte le Mercure, et se joinct et attache au regule de l'Antimoine. Et se sentant pressé et chassé par la chaleur, dissoult et calcine le regule, et passe en liqueur gommeuse ou huileuse par le bec de la cornuë; et tombant goutte à goutte dans l'eau qui est dans le recipient, l'esprit de vitriol se dissoult dans l'eau, et le regule tombe en poudre blanche au fonds du recipient. Cecy se recognoist au goust de l'eau qui est impregnée de l'esprit vitriolic, et à la fusion de la poudre emetique à fort feu de soufflets, laquelle se tourne en vray regule d'Antimoine. Davantage apres que toute la liqueur gommeuse est distilée, ne reste plus dans la cornuë que le mercure du sublimé et le soulphre de l'antimoine. Et parce qu'ils ont une extreme sympathie par ensemble en donnant feu de suppression, ils se subliment par ensemble au col de la cornue en cinabre. Je concluds donc par ces experiences infaillibles, que la poudre emetique n'est autre chose que le regule d'antimoine calciné, par l'esprit vitriolic qui est dans le sublimé."

This remarkably penetrating explanation of the reaction between antimony sulphide and mercuric chloride, together with the observation of the hydrolysis of the antimony chloride by water, has—to the best of my knowledge—been overlooked hitherto. It says much for Béguin's chemical instinct, and at once reminds us of the careful theorising of Black a century later. It is certainly a pleasant relief from the vapourings of contemporary alchemists. Béguin completes his explanation by what I imagine to be one of the earliest graphical formulæ:—



This expresses the facts: (*a*) that mercury sublimate consists of mercury and an "acid radical," as we should say now; (*b*) that antimony (*i.e.*, stibnite, Sb_2S_3), consists of a metallic regulus and sulphur; and (*c*) that when the two substances are heated together the acid radical of the sublimate combines with the regulus of the stibnite, while the sulphur and mercury thus set free combine to form cinnabar. Béguin also observed that the antimony chloride lost more or less of its acid radical on treatment with water, and that the water itself became acid in the process.

White Precipitate.—Dissolve mercury in *aqua fortis*, and add a solution of salt. A white precipitate is obtained, which must be washed until free from acid, dried, washed with rose water and dried again.

Red Precipitate. Dissolve mercury in nitric acid and evaporate to dryness in a strong fire. A red precipitate will be left This is a very useful medicine, since it is a sovereign purgative in leprosy. It may be given without danger to women and young children, and the dose is six grains.

Space will not permit the description of Béguin's methods of preparing stannic chloride, yellow oxide of mercury, fulminating gold, and many other substances, but one cannot close this article without noting the fact that he describes for the first time the preparation of benzoic acid from gum benzoïn.* "Take benzoin coarsely powdered and put it in a round pot, which cover with a cornet of grey paper . . . then administer the sublimation fire, and collect at frequent intervals the flowers which have sublimed. They are white as snow, and are none other than the essential salt of Benzoin . . . they are a very proper remedy for pimples and redness of the face."

The book ends with the quotation, "L'homme brutal ne cognoistra point, et le fol n'entendra à ces choses."

* The origin of the word *benzoin* is interesting, especially since it is itself the root of those honoured words *benzene*, *benzoïc*, *benzoyl*, etc. Benzoin or benjoin is a corruption of *lubān jāwā*, which is the Arabic for *incense of Java*, the best sort of incense coming from Sumatra, which the Arabs erroneously called Java. When the name *lubān jāwā* reached Europe, the first syllable was mistaken for the definite article *al* and therefore dropped. The *bān jawā* thus left finally became converted into benjoin or benzoin

The late Mr. J. C. Hewlett, chairman of C. J. Hewlett and Son, Ltd., manufacturing chemists, and a fellow of the Chemical Society, left estate of the gross value of £144,711, with net personalty, £114,840.

CHEMICAL ENGINEERING AT THE BRITISH EMPIRE EXHIBITION

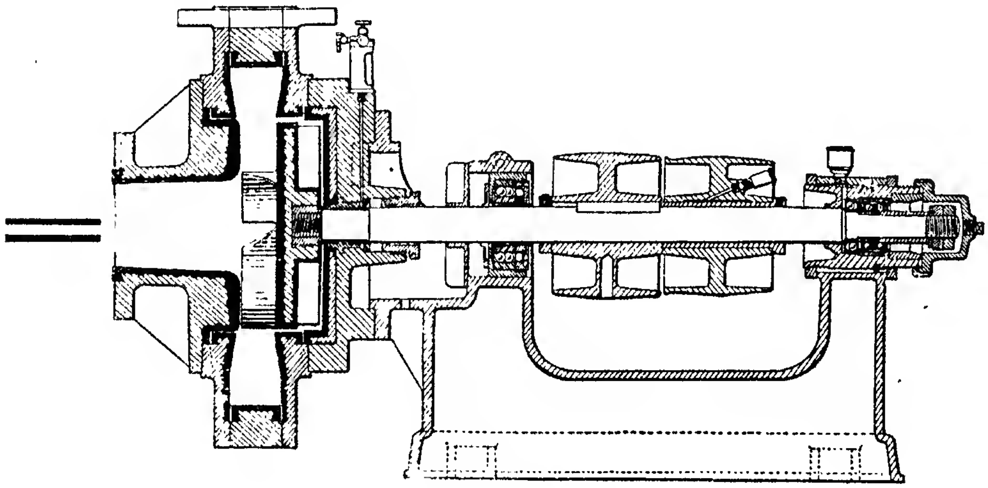
By Prof. J. W. HINCHLEY

(*Continued*)

The illustration (Fig. 7) of the "Resiline" Pump by the Pulsometer Engineering Co., Ltd., brings out the high standard of its design. Ball bearings support the spindle, and a ball thrust bearing maintains the exact position of the impeller to give the minimum "slip." The loose pulley is smaller than the fast one—a small matter, but a real economy in belting and power.

The "Reform" Dust Collector, which is shown at work by Henry Simon, Ltd., of Manchester, although designed for the flour-milling industry should prove an excellent air filter for use in many other dry grinding operations. The filter consists of a number of vertical cloth filter sleeves, arranged in a case in groups. By a simple mechanism the dust-laden air is shut off from each group of sleeves in turn, and a current of pure air drawn through them in a reverse direction. While this pure air is passing through, the sleeves are shaken vigorously several times to dislodge the dust clinging to their surface, which falls into a hopper below.

What may be considered a new process of separating particles according to size is shown, at work on grain, on the same stand. The "Carter" Separator consists of series of discs rotated together on the same horizontal shaft. Each disc is provided with depressions over its surface on both sides, and corresponding in size to the position of the disc on the machine, or rather, to the size of grain to be lifted at that position. It will be realised that if the grain is made to pass from one end of the machine to the other, the removal of grains according to size may be accomplished by the larger grains at any point failing to be lifted by the depressions in the disc provided. The efficiency of the machine on grain is remarkable, and apparentl much higher than would be possible by a siftin process.



The "Resiline" Pump

FIG. 7

The Peebles Sand Washer for the sand of filte beds should be examined. It consists of a series c hoppers and washing chambers through which th sand passes, and in which in turn it is submitte to the action of jets of water. The wash wate makes a complete cycle through the sections, an is effectively used before running to waste.

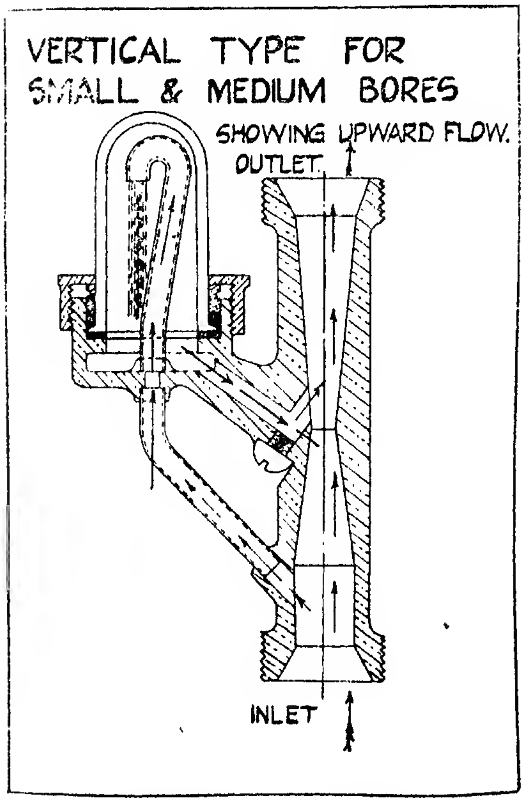
A simple sight flow indicator (Fig. 8) for liquids unde pressure is shown by R. and W. Hawthorn, Lesli and Co., Ltd., of Newcastle-on-Tyne. The apparatu is placed in the pipe line and consists of a Ventu tube, that is, the bore of the tube is gradually con stricted and over the tube a chamber with a vertica glass bell is provided. A small curved pipe lead from the inlet to the top of the glass bell, and a smal opening is made in the base of the glass bell chambe leading to the constriction. On account of the diffe ence in velocity produced the pressure at the constric tion is lower than at the inlet, and a portion of th liquid rises through the little tube leading to the to of the glass bell, and may be seen discharging. Th indicator is said to work effectively at velocitie as low as one foot per second.

The Howden-Ljungstrom Air Preheater shown b James Howden and Company, Ltd., of Glasgow, for use in boiler plants, introduces a new principle in continuous heat exchangers—discontinuous heat exchangers on similar lines are well known. Now, the problem of heat transmission between gases is a difficult one on account of the low rate of heat transfer. A notion of this difficulty will be realised when it is stated that heat transmission by saturated steam to water with the same temperature drop may be over five hundred times greater than between gases. This pre-heater avoids a large portion of this difficulty by using metal plate surfaces which are alternately carried into the currents of hot and cold gas, so that

in one part of the apparatus the gas heats the plates, and in another part the hot plates heat the cold gas. The metal plate surfaces are part of a cylindrical rotating member, carried in a vertical casing, divided vertically to form two conduits, one for the hot gases to heat one side, and the other for the cold air to be heated by the other side of the rotating member. The gas and air pass in opposite directions, *i.e.*, counter current heat transfer takes place.

Among the accessories exhibited, the level indicator of Dewrance and Co., London, ought to find many applications. A series of louvres are placed behind the ordinary gauge glass and an electric lamp is fitted near the bottom of the tube. The level of the liquid is seen by the meniscus being illuminated and appearing as a bright red glow.

Another device which is only novel in the excellent way in which the design is carried out is "Tompkins Tangential Drier" (Fig. 9) for steam. It consists of a compact box which may be placed in any pipe

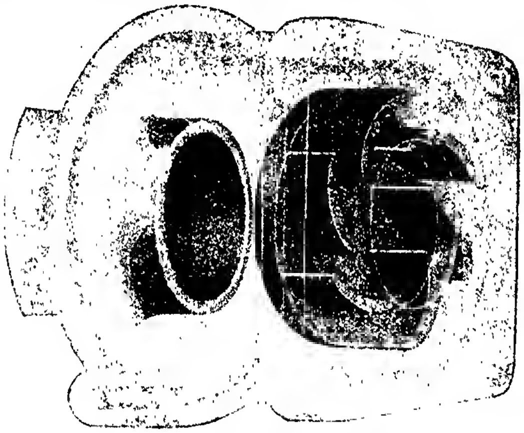


Hawthorn Sight Flow Indicator

FIG. 8

line. The box contains a fixed set of turbine blades which produce an energetic whirling of the steam by which the water is projected on to the inner surface of the box and flows away through the small pipe provided. It forms an excellent "save-all."

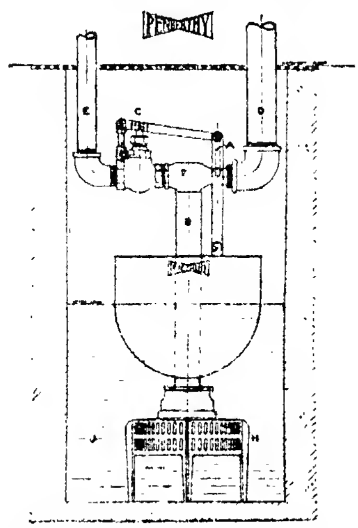
An automatic cellar drainer (Fig. 10) is shown at work by W. H. Willcox and Co., Ltd., London. It consists of a compact and well thought out arrangement of



Tompkins' Tangential Drier

FIG. 9

an ejector, a float and a valve with a strainer and foot valve. The float actuates the valve of the ejector in such a way that it is never partially open—always fully open or shut. Failure through corrosion or through deposits of slime etc. is prevented by the working parts being above the level of the liquid.

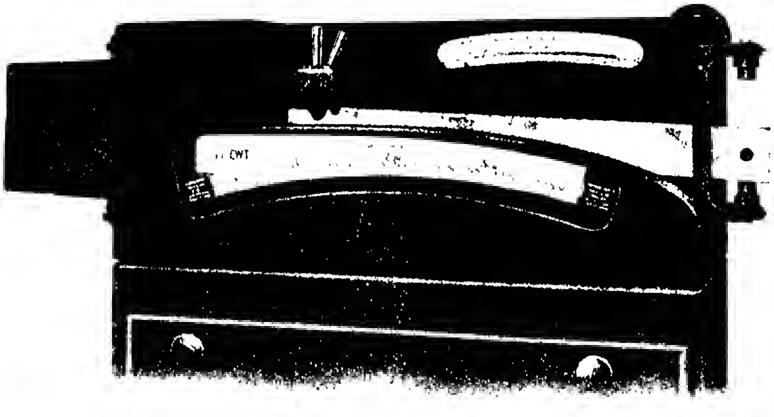


Penberthy Automatic Cellar Drainer

FIG. 10

The distribution of superheated steam is a more economical process than that of saturated steam. The heat losses are lower because the superheated steam acts as a permanent gas and a stationary somewhat non-conducting film is formed on the

inner surface of the pipe. With saturated steam on the other hand, the formation of a film is prevented by continuous condensation. Consequently, saturated steam is essential for economical heat transference, so that in many works superheated steam must



Avery's Platform Weighing Machine
Fig. 11

be converted into saturated steam at the plant where it is to be used. An interesting application of the "Area" regulator for this purpose is demonstrated by British Area Regulators, Ltd This regulator is well known for its precision in controlling the pressure, temperature, humidity or other physical condition in chemical plants. The regulator depends for its precision of action on a hydraulic relay device. The free flow of water from a small jet is affected by the movement of a lever. The difference of pressure produced actuates a pilot valve which in turn controls the supply of water to a hydraulic cylinder operating the regulating valve or other mechanism. For desuperheating steam, water is sprayed through a series of jets under the control of the regulator so as to reduce the temperature of the steam to the desired figure regardless of the quantity of steam passing.

Measurement in factories is the root of all sound commercial and technical control, and any improvement which renders mistakes difficult, increases accuracy, or saves time and mental worry should not be neglected

An improvement in platform weighing machines is shown by W. and T. Avery, Ltd., Birmingham (Fig. 11) On placing the goods on the platform an indicator shows the notch in which to place the poise for the hundredweights, and the minor reading, quarters, pounds, and ounces are shown by the indicating finger on the chart. If the poise is placed in the wrong notch, the indicator directs attention to the correction required. An improved protection bar, with Vee instead of square notches, is fitted to prevent wear and damage to the Vee notch on the steelyard.

In this respect it is a matter for comment that few firms adopt a single unit of weight in their works. The errors and loss of time which accrue from the use of 56, 28, 14, 7, etc. pound weights with ounces as sub-divisions are not appreciated, until one has realised the delightful simplicity of working with pounds only on a decimal system. Why do not firms who make weighing apparatus help manufacturers to adopt a method which is so advantageous?

(To be continued)

SMOKE POLLUTION IN FRANCE

A Police Ordinance of the Municipality of Paris, dated June 22, 1898, forbids the production of a thick and prolonged black smoke which might reach neighbouring habitations and vitiate the atmosphere of the streets of Paris. Using this Ordinance as a basis the Ministers of Commerce, Public Works, Interior Work, and Hygiene, have distributed throughout France a circular of which the following is a translation: "The Carbonisation Commission attached to the Ministries of Commerce and Public Works, has been struck, whilst studying means of favouring the development of the carbonisation of coal, with the necessity of restricting as far as possible the consumption of "fat" and "flaming" coals in a crude state, the scientific utilisation of these fuels consisting in previous carbonisation to remove volatile products and of burning them afterwards solely in the form of coke. An excellent method of obtaining this result would be to forbid the production of smoke in urban districts as has been done in Paris. In certain regions where special fuels are produced such as lignites or coals, with too high an ash content to be carbonised economically, and which will still have to be utilised in a crude state, measures of prohibition should be taken with precaution, and allowing sufficient time so that the adaptation of plant can be made progressively."

FORTHCOMING EVENTS

June 28. MINING INSTITUTE OF SCOTLAND. General Meeting, at City Chambers, Kirkgate, Dunfermline, at 3.30 p.m.

July 3. INSTITUTION OF CIVIL ENGINEERS, Great George Street, Westminster, S.W. 1, at 5 p.m. Joint Meeting with various Engineering Institutions and Associations, the Institute of Chemistry, the British Electrical and Allied Manufacturers' Association, and other bodies which are co-operating in the work of the Special Committee on Tabulating the Results of Heat-Engine and Boiler Trials. A paper will be presented by Capt. H. Riall Sankey, C.B., C.B.E., upon the General Scope and Objects of the Work of the Committee, and there will be a discussion.

July 5. INSTITUTION OF MECHANICAL ENGINEERS, Joint Meeting with the Institution of Civil Engineers, Storey's Gate, St. James's Park, London, S.W. 1, at 11.30 a.m. Discussion on "Draft Standard Test Code for Hydraulic Power Plants."

July 7–10. INSTITUTION OF SANITARY ENGINEERS International Conference at the Royal United Service Institution in Whitehall, S.W., at 10 a.m. and 2 p.m. On July 8 papers will be read on "Activated Sludge," and on July 9 on "Sewerage" and "Disposal of Sewage and Trade Wastes."

July 9–12. SOCIETY OF CHEMICAL INDUSTRY, Annual General Meeting to be held at Liverpool.

July 15. THE INSTITUTE OF CHEMISTRY STUDENTS' ASSOCIATION (LONDON). Visit of Chemical Students to Wembley. At 9.45 a.m. an Inaugural Meeting will be held at University College, Gower Street, W.C. 1, at which the President of the Institute, Prof. G. G. Henderson, LL.D., F.R.S., will take the chair. Mr. W. J. U. Woolcock, C.B.E., General Organiser of the Chemical Section of the Exhibition and President-elect of the Society of Chemical Industry, will explain the objects of the exhibits and the special features of interest. Prof. W. P. Wynne, C.B.E., F.R.S., President of the Chemical Society, hopes to support the speaker at the meeting. The cost of the visit, including return ticket to Wembley, entrance to the Exhibition, and ticket for luncheon, will be 5s. Further information can be obtained from Mr. G. S. W. Marlow, 30, Russell Square, London, W.C. 1, and applications should be made not later than June 28.

July 16. INSTITUTION OF CHEMICAL ENGINEERS, Annual Corporate Meeting, at the Hotel Cecil, Strand, London, W.C. 2, at 11 a.m. At 12 noon the presidential address will be delivered by Sir Arthur Duckham. After luncheon at 1 p.m. (price 6s., excluding wines) Sir F. Nathan will review the work of the Educational Committee on "The Training of a Chemical Engineer," and at 3.30 p.m. the following papers will be read:—(1) "Self balancing Centrifugals," by E. A. Alliott. (2) "Evaporation in Currents of Air," by G. W. Himus and J. W. Hinchley. After tea, at 5 p.m., members will proceed to the British Empire Exhibition, and a tour of the Chemical Hall will be made under the guidance of Mr. W. J. U. Woolcock.

SOCIETY OF CHEMICAL INDUSTRY

ANNUAL GENERAL MEETING, 1924

PATRON: H.M. THE KING

The Annual General Meeting of the Society of Chemical Industry will be held in the Arts Theatre, The University, Liverpool, on Wednesday, July 9, 1924, at 10.30 a.m.

A detailed programme with form of application for tickets has been sent to every member of the Society.

Attention is drawn to the following alterations:

Wednesday, July 9, 2.30 p.m. Visit to White Star liner *Celtic* (instead of *Cedric*), and tea on board by invitation of the White Star Line.

Thursday, July 10. The Messel Memorial Lecture will be given at 9.45 a.m. (not 10.30) in the Arts Theatre, The University, and the visit to the works of Messrs. J. Crosfield & Sons, Ltd., Warrington, will be at 11.30 a.m. (not 12.30 p.m.)

Delegates will be present at the Meetings from several of the Allied Societies at home and abroad. Among these will be Prof. Dr. C. F. Van Nieuwenburg of Delft, President of the Dutch Chemical Society.

Members intending to attend the Meeting are requested to send their applications, accompanied by the appropriate remittances to cover tickets and cost of travelling, at once to Mr. E. Gabriel Jones, City Laboratories, Mount Pleasant, Liverpool, to whom all enquiries relating to railway travelling and other matters connected with the Meeting should be addressed.

The Midland Adelphi and the North-Western Hotels are both very nearly full for the period of the meeting. Members intending to be present, and who have not yet booked Hotel accommodation, should therefore do this at once.

OFFICIAL NOTICES

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

The eighth volume of these Reports is now ready. The price of the book is 7s. 6d. to members of the Society, and 12s. 6d. to non-members, post free in each case.

A Member of the Society may purchase a set of Vols. II to VIII inclusive at the reduced price of £2 2s. 6d., and a Non-Member can procure a set at the reduced price of £3 15s., post free in each case.

CHEMICAL SOCIETY'S LIBRARY

Members are reminded that, in accordance with arrangements entered into by the Council, they are entitled to consult the Library of the Chemical Society, Burlington House, Piccadilly, W. 1, and to borrow books therefrom.

The Library is open daily from 10 a.m. to 9 p.m., Saturdays from 10 a.m. to 5 p.m. As hitherto the Library will be closed on Bank Holidays, the day following, and on other such occasions as the Council may direct.

CHEMICAL SOCIETY

At an extraordinary general meeting, held at 7.45 p.m. on Thursday, June 19, the President, Prof. W. P. Wynne, F.R.S., explained the policy reflected by the resolutions, which were all carried in the form in which they were circulated to Fellows.

The last ordinary scientific meeting of the session followed, when the President expressed appreciation of the honour done to the Society by the presence of Prof. R. Nasini: he also referred with deep regret to the death of Dr. R. M. Walmsley. It was announced that the list of Fellows would not be printed this year, that Vol. V. of the Collective Index would now be sold at the price ruling prior to January 1923, and that the charge for the Annual Reports would in future be:—to Fellows, 5s 6d. post free (second and subsequent copies 8s. 6d. post free); to others, 10s. 6d. plus postage.

Prof. D. R. Boyd discussed:—

Hydrolysis, and the theory of induced alternate polarities.

The theory of induced alternate polarities has recently been made the basis of a comprehensive generalisation with regard to the phenomena of hydrolysis:

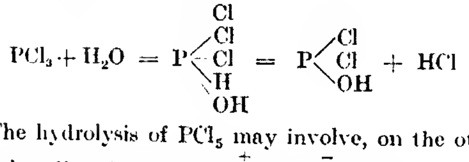
"The condition which facilitates the hydrolytic fission of a molecule —*ab*— into —*aH HOb*— is that *a* should be electronegative and *b* electropositive either because of their inherent character or as the result of an induced alternate polarity effect." (Robinson and Robinson, *T.* 1923, **123**, 533).

The application of this rule to compounds of the type RX, where X is a halogen, leads, however, to conflicting results. The hypothesis also fails to explain why compounds such as

$$(\overset{+}{C}_6H_5\cdot\overset{-}{O}\cdot\overset{+}{C}H_2)_2\overset{-}{C}H\quad\overset{-}{O}\cdot PHO(OH)$$

(Boyd, *T.* 1901, 79, 1223), are much more stable than $\overset{-}{C}H_3\ \overset{-}{O}\cdot PHO(OH)$; and why $\overset{+}{K}\cdot\overset{-}{SO_2}\overset{+}{O}\ \ C_2H_5$ is hydrolysed much more easily than $\overset{+}{K}O\cdot SO_2\cdot\overset{-}{O}\ \ C_2H_5$.

It is considered unlikely that the mechanism of hydrolytic fission is the same in all cases. The first step in the hydrolysis of PCl_3 probably consists in the formation of an additive compound:



The hydrolysis of PCl_5 may involve, on the other hand, a dissociation into $\overset{+}{P}Cl_4$ and $\overset{-}{Cl}$ ions:

$$\overset{+}{P}Cl_4+\overset{-}{Cl}+\overset{+}{H}+\overset{-}{O}H = PCl_4\cdot OH+\overset{+}{H}+\overset{-}{Cl}$$
$$PCl_4\cdot OH = POCl_3+HCl$$

It is not improbable that the first step in the hydrolysis of ethyl chloride is also an electrolytic discussion:—

$$C_2H_5Cl \rightleftharpoons C_2H_5^+ + Cl^-;$$
$$C_2H_5^+ + Cl^- + H^+ + OH^- \rightarrow C_2H_5OH + H^+ + Cl^-.$$

The hydrolytic fission of ethyl chloride is, on this view, closely comparable with the hydrolysis of sodium phenoxide:—

$$C_6H_5\cdot ONa \rightleftharpoons C_6H_5O^- + Na^+$$
$$C_6H_5O^- + Na^+ + H^+ + OH^- \rightarrow C_6H_5\cdot OH + Na^+ + OH^-$$

If, however, the Robinson rule is tested by reference to data with regard to the hydrolysis of the sodium tolyloxides (Boyd, *T.*, 1915, **107**, 1540), results are obtained which are in direct conflict with the views which have been developed by Lapworth and Shoesmith (*T.*, 1922, **121**, 1392) on the basis of the same experimental facts.

The discussion was opened by the Secretary reading the following contribution from Prof. Robinson:—

"The examples given by the author in the slip printed for circulation before the meeting are held to be wrongly interpreted. In the case of the diphenoxy*iso*propylphosphorous acid the effect of steric hindrance, always to be taken into consideration as an important factor, has not been mentioned, and is probably responsible for the stability of the compound. Even the polar effect would make it more stable than the methyl ester figured for comparison because of the powerful effect of the two oxygen atoms of the phenoxy-groups. Relatively to methyl, diphenoxypropyl must be a negative group.

The two mechanisms given for the hydrolysis of chlorides of phosphorus are obviously in agreement with the statement of the conditions of ready hydrolysis made by Robinson and Robinson. It is a confusion to include the phenomenon of the hydrolysis of salts of weak acids in this discussion."

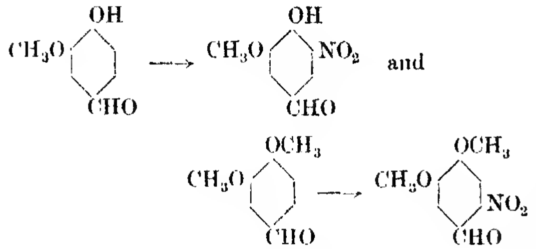
Prof. Lowry said that he saw no justification for the assumption of alternate polarities in the case of saturated compounds. The idea of ionic behaviour in organic reactions (the ions being formed in the course of the reaction) was put forward by Noyes in 1902; it was of interest to note that auric chloride formed not only the compound $AuCl_3$, HCl or $H^+[AuCl_4]^-$, but also one with phosphorus pentachloride which he was tempted to write $[PCl_4]^+[AuCl_4]^-$. If this formulation were acceptable, strong support would be afforded to Prof. Boyd's formulation $[PCl_4]Cl$.

Prof. G. T. Morgan said that it was difficult to get at close quarters with a theory the exponents of which continually shifted their ground. He considered the stability of the phosphorus compounds to be a question of their tetrahedral structure, in accordance with the characteristic co-ordination number 4 usually exhibited by phosphorus.

Dr. Flürscheim, who was in general agreement with Prof. Boyd's and Prof. Morgan's criticisms, said that in the triphenylmethyl halides Prof. Boyd had adduced especially important evidence. Ionisation, which alone involved proved electric charges on atoms, was pronounced in this case, where a central carbon atom, claimed to tend to assume an unproved negative charge, actually acquired a proved positive charge; it was negligible in carbon tetrachloride where carbon, with a postulated tendency to become positive, actually refused to acquire a *real* positive charge. Similarly, *p*-hydroxy-

cinnamic acid, with an enhanced "induced negative polarity" of carboxyl-oxygen, was weaker than cinnamic acid, whereas the meta-isomeride was stronger; a number of substituted benzoic and aliphatic acids behaved similarly. Here other factors, such as general polarity, could obviously not be invoked in explanation, and the facts must be unequivocally faced.

Dr. O. L. Brady referred to the two nitration effects :—



and enquired how these results could be reconciled with the polarity theory.

Prof. W. H. Perkin did not admit the reality of the difficulty, since unpublished work had shown that the nitro-group enters both positions to almost the same extent; separation had been effected by way of the *p*-toluidine compounds.

Prof. C. K. Ingold welcomed Prof. Boyd's paper as a much needed protest against *ex cathedra* utterances relating to the polarity theory, and the chosen evidence by which it was often upheld; moreover, the type of criticism employed was very widely applicable. If the phenyl group were, as had been stated, a key-position, the ambiguous polarity of an ethylene molecule should be determined by the introduction of a phenyl group in the direction $PhCH:CH_2$; the addition of $\overset{+}{H}-\overset{-}{Hal}$ and $\overset{-}{HO}-\overset{+}{Hal}$, replacement of H by NO_2, and replacement of H by OH then all proceed in a direction contrary to that indicated by the theory. The speaker protested against a series of reactions of no greater weight than these being "explained" in the Annual Reports on the assumption that the phenyl group is the key-position, and without reference to the adverse evidence.

In reply to Prof. Robinson, Prof. Boyd pointed out that the theory of induced polarities did not account for the extreme instability of methylphosphorous acid. It was difficult to understand how the processes of hydrolysis of the chlorides of phosphorus —assuming the mechanisms in the two cases to be essentially different in character—could both be conditioned by the same factor, namely, the polar differentiation between phosphorus and chlorine. Prof. Robinson's objection to the inclusion of cases of salt hydrolysis in the discussion was obviously unjustified if the hydrolysis of such compounds as ethyl chloride was preceded by an electrolytic dissociation.

Dr. O. L. Brady then spoke on :—

The isomerism of the oximes. Part XX. The isomeric p-*nitrobenzophenoneoximes and the four methyl ethers derived from them.* (With R. P. Mehta.)

THE stereochemical hypothesis of the isomerism of the oximes demands the existence of four isomeric ethers, an oxygen and nitrogen ether corresponding with each of the two isomeric oximes. Although two isomeric O-ethers had been obtained from certain aldoximes and ketoximes, until 1918 all attempts to obtain a second N-ether had been unsuccessful. Semper and Lichtenstadt (*Ber.*, 1918, **51**, 928), however, prepared two N-methyl ethers from phenyl-*p*-tolylketoxime, but, though they isolated two O-methyl ethers, one was an uncrystallisable oil and consequently of doubtful purity. The importance of this in relation to the structure of the oximes demanded confirmation and the isomeric *p*-nitrobenzophenoneoximes have now been prepared and from them four distinct, crystalline, methyl ethers. *anti*-*p*-Nitrobenzophenoneoxime (I) on methylation gives a yellow crystalline N-methyl ether m.p. 148° and a colourless crystalline O-methyl ether m.p. 94°. *syn*-*p*-Nitrobenzophenoneoxime (II) gives a yellow crystalline N-methyl ether m.p. 176° and a colourless crystalline O-methyl ether m.p. 97°.

$$\begin{array}{c} NO_2{\cdot}C_6H_4{\cdot}C{\cdot}C_6H_5 \\ \| \\ NOH \end{array} \qquad\qquad \begin{array}{c} NO_2{\cdot}C_6H_4{\cdot}C{\cdot}C_6H_5 \\ \| \\ HON \end{array}$$

(I) (II)

The constitution of the ethers was proved by the action of hydriodic acid, the O-ethers giving methyl iodide and the N-ethers methylamine. The molecular weights were normal in every case. The two N-ethers differ in crystalline appearance as do the two O-ethers; addition of a small quantity of one N-ether to the other lowers its melting point and the same is the case with the two O-ethers, a mixture of about equal quantities of the latter melting at 61-72°.

Prof. W. H. Perkin expressed his keen appreciation of the author's work on oximes. With reference to Dr. Brady's criticism of Meisenheimer's suggestion that the Beckmann change occurs across the molecule :—

$$\begin{array}{c} R{\cdot}C{\cdot}R' \\ \| \\ HON \end{array} \longrightarrow \begin{array}{c} R{\cdot}C{\cdot}OH \\ \| \\ NR' \end{array}$$

he had also come to the conclusion that the suggestion could not be accepted without much further work.

Mr. E. M. Richards read a paper on

The significance of simple rotatory dispersion. (With T. M. Lowry.)

THE phenomenon of simple rotatory dispersion is discussed in the light of new experimental data, with reference especially to camphorquinone, ammonium bromo-camphor-π-sulphonate and methyl*cyclo*hexylideneacetic acid.

Owing to the lateness of the hour, the communication of the latter portion of the paper was postponed.

At the President's invitation, Prof. Lowry rapidly summarised the paper, saying that it dealt with a new test for, and demonstrated the existence of, simple rotatory dispersion. If the two rectangular hyperbolas obtained by plotting α against λ^2 were averaged along a series of horizontal intercepts, the vertical asymptote of the resulting genuine hyperbola would be intermediate between those of the parent curves; the false hyperbola, obtained by averaging the parent curves vertically would, if treated as a genuine hyperbola, swing aside from the asymptote. The genuine hyperbola would always have as its asymptote the central line of a real absorption-band, whilst the false hyperbola would be directed into empty space.

Mr. H. Hunter offered his congratulations, but desired to withhold any further comment until he had seen the paper.

Dr. R. H. Pickard said that Mr. Hunter's papers had brought forward work giving proof of a point which had been dubious. It must, however, be remembered that the refinements of polarimetry were still not great, and the limit of work was at about λ3800. The experimental evidence showed that the overwhelming mass of organic compounds of "respectable" purity are of a nature expressed by one term of Drude's equation.

ACADÉMIE DES SCIENCES

At the meeting on June 2, L. Gentil communicated a further paper by M. Lazarev on the deposit of magnetic iron at Koursk, Russia, and estimated the quantity of iron in the northern belt at 34 milliard tons. M. D'Arsonval described, on behalf of M. Seillard, a new type of portable electrometer which could replace the dial electrometer in most of its applications. This new and delicate instrument allows measurements to be made without special plant or the use of high-tension batteries or reflected light, whether in the works or in the laboratory. The millionth part of a millionth of an ampere is indicated by a rigid needle on a fixed scale similar to an ordinary amperemeter and measurements impossible to the ordinary electrometer can be undertaken. During the meeting M. Charles Rabut was elected a member of the Académie des Sciences in the section of the applications of science to industry in place of the late Maurice Le Blanc.

On June 10, Monsieur Rateau communicated a note by M. Dumanois on "The use of light alloys for motor pistons," showing that the use of magnesium alloys might be useful in light engines, aluminium alloys being more suitable for larger engines on account of their heat conductivity.

Prof. Moureu gave an account of the rare natural gases, summarising the researches he has carried out on this subject with M. Lepape.

M. Haller showed that by the action of tetrachloroplatinic acid, turpentine combined directly with formic acid and with benzoic acid. This reaction led to the preparation of borneol and thence to synthetic camphor resembling natural camphor.

Prof. Le Chatelier drew attention to work on the lignites, showing that on distillation this fuel gives one and a-half times as much gas as does coal.

CORRESPONDENCE

BACTERIOLOGICAL TRAINING FOR CHEMISTS

Sir.—The article contributed to *Chemistry and Industry* (June 6) by Dr. David Ellis of Glasgow, on the training of chemists in bacteriology, should be read most carefully by all chemists, but more particularly by those who are seriously interested in the future of chemical training. There can be no question that we are rapidly approaching a stage in the history of chemical education in our Universities when drastic revision of the courses will be necessary. Parallel with the rapid advances in knowledge which have taken place in the many branches of chemistry during the past twenty-five years there has been in the majority, if not all, of our Universities so wide an extension of the syllabus, and so great an increase in the demands made on the candidate for Honours at the Final Examinations, that we may ask in all fairness whether the burden is not become already too heavy.

We must also recognise that the regrettable tendency to early specialisation which characterises much of our modern chemical training is undoubtedly largely responsible for the fact that the average graduate with Honours in Chemistry leaves the University at the end of three years with little or no education, apart from a knowledge of his chief subject; even those who spend a fourth year in study seldom devote the extra time to widening their outlook on science or on life.

Many will reply that the University courses in chemistry are already too short to enable a student to be trained adequately in that subject alone, and that attractive as schemes to introduce other subjects into the syllabus may be on paper, they are impracticable. I would remind such people that there is a tendency to forget that the real function of a University is to educate, and that three years should suffice to transmit to a student a knowledge of the fundamental principles of science. It is generally recognised that the graduate in chemistry on leaving the University is usually of very little use until he has acquired the special knowledge in the new field in which he is working; this period, probably the most humiliating in one's career, may be said to be in most cases about twelve months. Surely, then, if we accept the principle that specialisation should come after graduation, it is of the greatest importance that the short time at college should be occupied in planting fundamentals in the students' minds, and in developing that breadth of vision and power of thinking which are essential to their success in after life.

These general considerations bring me to the main point of my letter, which is concerned with Dr. Ellis' advice "Go and get a biological training, no matter what the means by which this training is obtained." It is probably true that an estimate that 1 per cent. of graduates in chemistry leave our Universities with any knowledge of biology would be generous, and yet at least ten times as many will within a few years be faced with problems demanding for their solution some knowledge of the living cell and its activities. Even if we ignore

this essentially practical aspect of the matter, there remains the equally important one, which concerns the educational value of a biological training.

Is there not cause for serious reflection on our modern system of education when we bear in mind that whereas one who is ignorant of the classics and of literature is rightly considered to be an uneducated person, no such description is applied to the individual who passes through life ignorant of the great fundamental principles that govern living organisms?

Two points should be clearly kept in mind. In the first place, there is no need, indeed it would obviously be impossible, to ask that every student should make a detailed study of biology during the years at college. But it is not too much to ask that our Universities should seriously consider whether it would not be advisable for all students in the Faculty of Science to take a course of general biology during their first year, *i.e.*, to take an examination in this subject at the stage corresponding in London, and certain other Universities, to the Intermediate Examination in Science.

I have carefully examined this question and have satisfied myself that the proposal is a practical one, for in the majority of cases it would only necessitate a condensation of the somewhat diffuse course in mathematics which now takes up so large a proportion of the student's first year.

The mention of the subject of general biology brings me to the second point, namely, that for the large proportion of students the existing courses of botany or zoology would not serve to satisfy my demands; such courses deal to a large extent with systems of classification and morphology; subjects which should occupy only a small proportion of the course which I wish to see taken by science students in general, and which should be built upon the lines laid down in the famous course given years ago by Huxley and Ray Lankester.

We must look in this country for a revival, such as is actively in progress in the United States of America, of the experimental method in biological science, if botany and zoology are to be raised from the lamentable position into which they have fallen in the last few decades; but here I digress. My last plea concerns my own subject, biochemistry. Prof Donnan once remarked to me that looking into the future of chemistry he could see only two paths which were likely to lead to the opening up of vast fields of knowledge. They appear at first widely divergent, but some day they will converge, and with startling results. The first is the investigation of the structure of the atom and molecule, and the second is the study of the chemical processes of the living cell.

At least two universities in this country, Cambridge and London, now have large, well-equipped biochemical departments, but, speaking at any rate for my own department, I can say that, with a few exceptions, the right type of material is not coming forward to be trained. The demand for biochemists from research departments and from industry is steady, and is greater in proportion than in any other branch of chemistry, but we are seldom able to supply the right type of man; the well trained chemist who not only has knowledge of the special field of biochemistry but who also has what can be termed the "biological" mind. By this one means that his training enables him to view a problem not only from the chemical or physico-chemical aspect, but also from the standpoint of the living cell. Biochemistry should, in my opinion, be a subject for post-graduate study, and I view as the most suitable raw material the good honours graduate in chemistry who already possesses a sound general knowledge of the general principles of biology. The strength of my feeling on these matters, Sir, must be my excuse for asking you to give me so large an amount of your space. I consider Dr. Ellis has rendered chemistry a great service in raising the matter in his pregnant article.

I am, Sir, etc., J. C. Drummond
Professor of Biochemistry

University College,
London

ALUMINIUM COOKING VESSELS

Sir,—One sometimes hears it stated that food cooked in aluminium vessels is injurious to health. How has this idea originated? There can be no disputing the fact that people have been taken ill and have died after partaking of food cooked in an aluminium pan and there are numbers of cases where the same result has followed the going to bed. It would be interesting to know which of these habits is the more dangerous. I am not going to accuse those people of ignorance or superstition who believe in the dangers of aluminium, and I should like to know if there is any ground whatever for their fear. Is the material of which "aluminium" pans are made all that it should be? I am, Sir, etc.,

Joseph Barnes

Arnside, Westmoreland
June 23, 1924

THE DESIGNATION OF THE CHEMIST

Sir,—Prof Snell, in support of the word "chemor," gives a list of words having the termination -or, and challenges me "to produce by my original system of word formation a parallel to the word (chemorry) which I create to ridicule." Now of the words he gives, actor, auditor, doctor, pastor, procurator and tutor are unchanged Latin words, proctor is a syncopated form of procurator, and author is a modified form of the Latin auctor. They therefore differ fundamentally from "chemor" as regards their derivation, and it is impossible to deal with them in the manner suggested. The true parallel is to be found in the word "chemistry" itself, the derivation of which is given in Murray's Dictionary as chemist + -ry.

A more formidable objection to the use of the word "chemor" arises from a consideration of the sister sciences. Thus physics is practised by a physicist, geology by a geologist, botany by a botanist, etc., and, if your correspondent has his way, chemistry by a "chemor." It does not seem logical and I do not think it is philologically sound. Is not the title

chemist too ancient and honourable to be mutilated in this arbitrary manner ? The profession of chemistry is the victim of faulty legislation, culminating in the final Pharmacy Act of 1869, which gave the title chemist to a section of the community, who are not, in the proper sense of the word, chemists. The only absolute remedy would seem to lie in fresh legislation. It is difficult to believe that the adoption of an hybrid word like "chemor" would improve matters to any material extent.—I am, Sir, etc.,

JOHN S. BOUSFIELD

Cambridge
June 23, 1924

PERSONAL AND OTHER ITEMS

Yale University has conferred the honorary degree of D.Sc. on Dr. Banting, the discoverer of insulin.

We regret to announce the death, in his 72nd year, of Sir James Johnston Dobbie, F.R.S. Born in Glasgow in 1852, Sir James Dobbie was educated at Glasgow High School and Glasgow University. After a period at Leipzig University he became lecturer in mineralogy, and subsequently assistant to the professor of chemistry in Glasgow University. After twenty years as professor of chemistry in the University College of North Wales, he was appointed in 1903 director of the Royal Scottish National Museum, and from 1909 he held the post of Government Chemist until his retirement in 1920. He had been elected a Fellow of the Royal Society in 1904 in recognition of his numerous researches on the chemical constitution of the alkaloids and the relation between the chemical constitution and absorption spectra of organic compounds. His services to science were recognised by the bestowal of a knighthood in 1915. Sir James Dobbie was President of the Institute of Chemistry from 1915 to 1918, and President of the Chemical Society from 1919 to 1921. He also served on the Royal Commission on awards to inventors. It is hoped to publish an extended obituary in a later issue.

Smithells Fund

Some time ago a movement was started through the University of Leeds for raising a Fund with the object of signalising the distinguished services which Prof. Arthur Smithells had rendered to the community in so many directions, and particularly to the science of Chemistry and the University of Leeds, during his thirty-eight years tenure of office as Professor of Chemistry, which terminated at the end of the session 1922-1923.

The Fund has been generously supported by the colleagues of Prof. Smithells on the Council and Staff of the University, personal friends, old students from all parts of the world, and by those connected with industries (notably the gas industry) who have desired to express in this practical way their appreciation of his sympathetic attitude and valuable assistance.

All who have interested themselves in the movement will be pleased to learn that the attainment of its object is now secured. Mr. Fiddes Watt, R.A., has undertaken the commission to paint a portrait of Prof. Smithells for presentation to the University, and a fund of at least two thousand pounds will remain for the endowment of a Scholarship in the University of Leeds, bearing the name of Prof. Smithells and instituted along lines approved by him.

Details will be notified to subscribers in due course, but as the fund will shortly be closed, any further subscriptions to increase the value of the Scholarship should be sent at once to the Treasurer, The Smithells Fund, at Beechwood, Roundhay, Leeds.

The Jacksonian Professorship at Cambridge

Since the death of Sir James Dewar, the Jacksonian professorship of natural philosophy at Cambridge has been suspended. According to "Nature," as the chair is only partly endowed and funds are not available to complete the stipend, the Council of the Senate has proposed that the professor shall not necessarily be required to reside and that the appointment shall be for one year, or a maximum of two successive years. The object of the suggestion is to attract a succession of distinguished scientists to Cambridge and, if adopted, it would probably result in a powerful stimulus to university research in chemistry, physics and their biological aspects, the subjects to which it is proposed to confine the chair.

A New Chemical Society

The announcement of the formation of the Indian Chemical Society, with headquarters at Calcutta, is of considerable interest, and the new body will have every wish for its success. The memorandum of association lays down a sound constitution for the Society, and the membership of the first Council gives every promise that the new body will do useful work. Sir P. C. Ray is the president, Dr. J. L. Simonsen and Prof. G. J. Fowler the vice-presidents, Prof. J. N. Mukhergee the secretary, Prof. P. C. Nutter the treasurer, and Dr. E. R. Watson the editor. It is understood that the first issue of the *Journal of the Indian Chemical Society* will appear in August.

Food Preservatives

According to "The Times" the Minister of Health has extended the terms of reference of the Departmental Committee on the use of preservatives and colouring matters in food so as to include the question whether and to what extent the practice of treating flour with chemical substances is objectionable on grounds of health, and whether it is desirable in the interest of the public health that the practice should be prohibited or restricted, and in the latter case what restrictions should be imposed. This question will be considered by the committee after they have completed the inquiry and presented their report upon the subjects for which they were originally appointed. The secretary of the committee is Mr. A. M. Legge, of the Ministry of Health, Whitehall, S.W., to whom all communications should be addressed.

REVIEWS

CHEMICALS. By A. W. ASHE and H. G. T. BOORMAN, A.I.C. The Resources of the Empire Series. Pp. 207. London: E. Benn, Ltd., 1924. Price 21s.

The book gives—so far as the authors have been able to obtain the information—the chief chemical products and requirements of the various countries forming the British Empire. It is very conveniently divided on a geographical basis, and contains much useful information on quantities and values of both exports and imports.

No useful purpose would be served by making extracts from the statistics given, as each branch of the industry will find easily, with the help of the very complete index, the figures and facts that are wanted.

From the very nature of the case the figures must not be taken too literally, but considered as a whole the authors may congratulate themselves on having compiled a very useful book.

It is unfortunate that there are one or two unnecessary mistakes, one of which had better be corrected as the dissemination of a mistaken definition can only cause confusion and the matter can be put right in any subsequent edition. On page 68 the statement is found that crude carbolic acid is generally sold as of two strengths, 50's and 60's. This is quite correct, and if the statement had been left at this point all would have been in order, but although this book is not a textbook, the authors go out of their way to explain what is meant by 50's and 60's, and give the wrong explanation. They say that 50's or 60's means that "50 or 60 per cent. of phenol will crystallise at 62·5° F." This is not the meaning. According to Lowe's method of testing crude carbolic acid, which is the test used in the trade, the expression 50's or 60's means that if, after distilling off 10 per cent. of the oil and all the water that may be present, you collect 62½ per cent. separately, and after thoroughly mixing you take the crystallising point of this 62½ per cent. fraction a 50's carbolic will crystallise at 50° F., and a 60's at 60° F., and so on.

With the conclusions and suggestions contained in the final summary the writer is in agreement but he fears that the Dominions and Colonies will manufacture any chemicals they require whenever they can do so more cheaply than they can buy them from the Home Country, and they can hardly be blamed.

An interesting note is to be found on page 190, under Bibliography, in which reference is made to the facilities afforded by the Dominion and Colonial Headquarters in London to seekers for information about their respective countries.

W. H. COLEMAN

KOHLENCHEMIE. By Drs. H. STRACHE and R. LANT. Pp. xvi+599. Leipzig: Akademische Verlag G.m.b. H., 1924. Price, paper, 24 goldmarks, bound 26 gm.

This is a work of a type which is often issued from German sources. The authors have set themselves the Herculean task of a comprehensive treatment of the chemistry of coal—exclusive of the manufacture and utilisation of fuels. They appear to feel that their purpose will not be achieved if they omit to refer, however lightly, to every imaginable aspect of the subject. It is obvious that even though they have run to 600 pages, they must fail at times. Depth of treatment must be sacrificed in the endeavour to cover the maximum area. One could quote instances where the treatment has become so slight as to be valueless. Thus in the one line devoted to Indian coal we are merely told that it is of low value. To realise the inaccuracy of this, one has only to recall that a young and vigorous coking industry supplying Indian iron blast-furnaces and foundries has already been established. Then the important subject of the behaviour of nitrogen and sulphur on carbonisation is dismissed in about one page, and there are many, including the writer, who would differ from some of the statements made. Although evidence is forthcoming that the authors are aware of recent studies of the problems in this country and elsewhere, they have not, it would seem, absorbed the results of this work.

The main and most valuable part of the work seems to be the chapters on the chemistry of coal, its origin, and the German work of recent years, especially on the carbonisation of coal at high and low temperatures. Great prominence is given to the labours of the Kohle Forschungs-Institut of Mulheim, the researches of which have already filled six volumes. The extensive bibliographic references, after each chapter will be of value even when the discriminating reader is dissatisfied with the text.

Considerable space is given at the end to the analysis of coal, and allowing for the prominence given to German practice the treatment is comprehensive, sound, and modern

It is on account of the good features mentioned that the book is to be recommended to students of coal and fuel technology, who will know how and when to exercise discrimination.

H. J. HODSMAN

THE RESIN INDUSTRY IN FRANCE

A lecture was recently delivered in Paris by Monsieur Dupont, describing the operations by which 130,000 tons of resin is collected annually in the Landes. After discussing the treatment of the crude material and the separation of the different products, turpentine, resin and tar, it was suggested that great improvements would result from the introduction of continuous vacuum distillation apparatus. The annual production of turpentine in France was 25,000 t., and of resin, 100,000 t., compared with 85,000 t. and 100,000 t. respectively in the United States, where the forests are being exhausted and internal needs are more and more restricting exportation. The production of pit props, masts, etc., was a flourishing industry in the Landes district, and a good future seemed in store for paper-making by means of pine pulp treated by the basic process.

LEGAL INTELLIGENCE

THE MANUFACTURE OF CHEMICALS BY A GAS COMPANY

On May 21, the Court of Appeal heard an appeal by J. L. Deuchar, Secretary of the Castner Kellner Alkali Co., Ltd., from the refusal of Mr Justice Astbury (*cf. Chem. & Ind.*, Jan 25, 1924) to make a declaration that the Gas Light and Coke Co. was acting *ultra vires* in manufacturing any chemical necessary for treating any of the products arising in making gas. The appellant said that the Gas company produced naphthalene and to convert it into betanaphthol had purchased chemicals from the Castner Kellner and other companies. Recently the Gas company had laid down plant to make caustic soda which, by reason of profits made on the gas undertaking might be sold even at a loss. The Gas company stated it manufactured caustic soda not for sale but only in such limited quantity as was necessary to treat the residual naphthalene. Mr Justice Astbury held that what the Gas Co. was doing was not *ultra vires*.

For the appellant, it was conceded that the Gas company might make articles produced from materials used in the manufacture of gas, or might convert residuals, but it could not start the business of making things which it used for converting residuals. It could not start a colliery business because it used coal, and it could not make caustic soda to produce chlorine which was to be turned into bleaching powder, nor could it sell the powder. The manufacture of caustic soda was not incidental to the powers vested in the company.

For the respondents, it was argued that one of the Gas company's businesses was that of converters of gas residuals. Unless an extension of business transformed the business into something else it had never been held that such extensions made *bona fide* were outside the powers of the company. In this case it was the more clearly within the powers of the company because one of the company's main stated objects was to deal with residuals. All that the Gas company had done was done in pursuance of one of its statutory powers. If the company had produced caustic soda for sale that might have made a difference, but its plant was only sufficient to produce the amount required.

The Master of the Rolls, giving judgment on June 20, said the ordinary commercial method of utilising naphthalene was to convert it into beta-naphthol by means of caustic soda. Formerly the Gas company purchased this, but had decided that it would be cheaper and more economical to make the caustic soda and had erected plant sufficient to supply requirements of this chemical, but no more. Incidental to the production of caustic soda, chlorine was produced, but that did not affect the company's power to make caustic soda. It was clear that the purposes and business of the Gas Light and Coke Company was two-fold: to make gas and to dispose of the residuals which had resulted from the process of making gas. It was not denied that the proper method of utilising naphthalene was to convert it into beta-naphthol and to do so caustic soda was needed. It must be provided, and there was nothing to cut down the right of provision. There being nothing to limit the right of provision and no express prohibition against manufacture, it would be taking too narrow a view to hold that the making of caustic soda lay outside the powers of the company. Lord Justices Warrington and Sargant concurred and the Appeal was accordingly dismissed.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Lead Paint Bill

On June 20, Mr. R. Davies moved the second reading of the Lead Paint (Protection against Poisoning) Bill The purpose of the Bill was to lessen the risk of contracting lead-poisoning among painters and its provisions had been drafted so as to enable the Government to ratify the International Convention on that subject. After discussing the statistics of white-lead poisoning, he said that the trade would have until November, 1927, to adjust itself. Paint of good quality could now be obtained free from white lead and was already used on a large scale in this country. The Home Office experts were satisfied that wet-rubbing down with waterproof sandpaper did not meet the case. The Bill would prohibit the employment of women and young persons in painting buildings with lead paint and would regulate the use of lead paint in other directions.

Mr. Harvey, in moving an amendment welcoming regulation, but opposing ratification of the Convention, quoted statistics to show that painters, were less affected by lead-poisoning than other industrial groups and pointed out that the experts of the Geneva Conference recommended a system of regulation and not prohibition for internal painting, and that the resolution of the Conference itself for prohibition was a compromise and not binding on this country. Referring to the finding of the Public Works Department that substitutes for white lead were inefficient, Mr. Harvey quoted Sir T. Oliver's statement that wet-rubbing down obviated danger of poisoning.

Mr. E. Grenfell, supporting the amendment, said that this country kept on passing legislation agreed to at Geneva, and in which none of our great competitors were ready to follow us. A decrease in the use of white lead would increase the price of zinc and also of painting and would reduce employment. The question should be left open and reconsidered in 1927.

Lord Cavendish-Bentinck supported the Bill mainly on humanistic grounds, and claimed there was no reason for hesitation. The white lead corroders could convert their premises and the workers would gain by employment in a healthy process. Mr Raynes, speaking in support, also welcomed the Bill, saying that there was an adequate substitute for white lead and that wet rubbing-down appeared almost impossible of application.

The Bill received a second reading on the understanding that if Clause I (prohibiting interior painting with white lead) were rejected in Committee, the remainder of the Bill would be proceeded with.

COMPANY NEWS

BOOTS PURE DRUG CO., LTD.

An interim dividend has been declared on the ordinary shares for the quarter ending June 30 at the rate of 9 per cent., less tax.

MAGADI SODA CO., LTD.

Mr. H. E. Burgess, the Senior Official Receiver in Companies Liquidation, has obtained the leave of the Court to call meetings of debenture holders, creditors and shareholders of Magadi Soda Co. to consider proposals for selling the property in the Kenya Colony to a new company to be formed by Messrs. Brunner, Mond and Co., Ltd. The notices will be issued in about three weeks, and, owing to the distance at which some of the parties reside the Court has directed that the meetings are to be held three months from that time. Under the scheme the first debenture holders will receive debentures for the same amount as in the old company and at the same rate of interest. The second debenture holders and the general body of creditors are to receive fully-paid preference shares, whilst the shareholders will receive fully-paid second preference shares, with the right to subscribe for another class of preferred shares carrying a higher rate of interest. Messrs. Brunner Mond and Co. have undertaken to provide the necessary working capital, and have given guarantees satisfactory to the Official Receiver and to the Colonial Office as to the extent to which they will work the undertaking.

CAPE ASBESTOS CO., LTD.

The report for 1923 shows a net profit after allowing for depreciation of fixed assets of £15,591 (£13,840 for 1922), and £5504 was brought forward. The addition is £2225 (against £5000), thus raising the fund to £65,750—equal to 50 per cent. of the issued capital. The basic dividend on the preference shares takes £2306, and out of the remainder of £16,564 it is proposed to pay a dividend of 10 per cent. (unchanged) on the ordinary shares; this requires £5497, and a similar amount is divisible as extra dividend on the preference shares. The carry forward is £5571.

W. J. BUSH & CO., LTD.

At the 27th annual general meeting, Mr. J. M. Bush, the chairman, said business conditions in 1923 resembled those in 1922. The increase in the net profit was due to the pre-war rate of depreciation on plant. The maintenance of the net profit was due largely to improved efficiency of processes in the fine chemical department and to working economies in the firm's factories. The fine chemical department had been greatly extended and had been fostered by the Safeguarding of Industries Act. In view of low wages on the Continent and depreciated currencies, the expiry of the Act in 1926 would be serious; the company might have to discontinue to make certain products. But several processes had been improved and he (the chairman) was confident that foreign competition in a number of products would be met. The subsidiary companies in the United States and Canada had made substantial profits.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

All grades of boric acid have been reduced by £3 per ton as from June 11. Borax prices are unchanged. Prices generally remain steady.

Acetic Acid, 40% tech. ..	£23 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	.. £45 per ton.
Powder ..	.. £47 per ton.
Acid Hydrochloric	.. 3s. 6d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	.. £21 10s.–£27 per ton makers' works according to district and quality.
Acid Sulphuric ..	.. Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali ..	.. £6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder	.. Spot £11 d/d., Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	.. £7 per ton, packages extra.
Borax, Commercial—	
Crystal	.. £25 per ton.
Powder ..	.. £26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	.. £5 17s. 6d. per ton d/d.
Methylated Spirit 64 o.p.—	
Industrial ..	.. 3s. 1d.—3s. 5d. per gallon, according to quantity.
Mineralised ..	.. 4s. 2d.—4s. 6d.
Potash Caustic ..	.. £30—£33 per ton.
Potass. Bichromate	.. 5¾d. per lb.
Potass. Chlorate ..	.. 3d.–4d. per lb.
Salammoniac ..	.. £32 per ton d/d.
Salt Cake	.. £3 10s. per ton d/d.
Soda Caustic, solid	.. Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals .	.. £5 5s—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	.. £24 per ton.
Sod. Bicarbonate	.. £10 10s. per ton, carr. paid.
Sod. Bichromate ..	.. 4¼d. per lb.
Sod. Bisulphite Powder 60/62%	.. £18—£19 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate ..	.. 3d. per lb.
Sod. Nitrate refd. 96%	.. £13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £14 10s. per ton d/d.
Sod. Sulphide cryst.	.. £9 per ton d/d.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	.. 5¾d.—1s. 4d. per lb., according to quality.

Crimson	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 11d. per lb.
Barytes	£3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide	3s. 9d. per lb.
Carbon Bisulphide	£24—£26 per ton according to quantity.
Carbon Black	6¼d.—6¾d. per lb. Market firmer.
Carbon Tetrachloride	£56 per ton, drums free.
Chromium Oxide, green	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	15s. per cwt., barrels free.
Lead Hyposulphite	7½d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£15 10s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Sulphur Chloride	3d. per lb., carboys extra.
Thiocarbanilide	2s. 9d. per lb.
Vermilion, pale or deep	4s. 10d. per lb.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

All prices keep fairly stable, but there is room for improvement in business.

Acetate of Lime—	
Brown	£14 10s. per ton d/d. Demand active.
Grey	£19—£20 per ton. Fair demand.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 per ton, according to grade and locality. Demand below normal.
Iron Liquor	1s. 7d. per gall. 32° Tw.
	1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 7d. per gall. Unrefined.
Wood Naphtha—	
Miscible	5s. per gall. 60% O.P. Market dull.
Solvent	5s. 6d. per gall 40% O.P. Fairly good demand.
Wood Tar	£5 per ton.
Brown Sugar of Lead	£16 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	6½d.—6¾d. per lb. Better inquiry.
Crude 60's	1s. 9d.—1s. 10d. per gall. Market flat. Only odd lots being offered.
Acid Cresylic, 97/99	2s 1d.—2s. 2d. per gall. Demand still good. Market firm.
Pale 95%	1s. 10d.—1s. 11d. per gall. Steady demand.
Dark	1s. 8d.—1s. 11d. per gall. Steady business.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	9½d. per gall. Very quiet.
Unstrained	8½d.—9d. per gall.
Benzole—	
Crude 65's	10½d.—1s. per gall. ex works in tank wagons.
Standard Motor	1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure	1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.
Toluole—90%	1s. 5½d. per gall.
Pure	1s. 10d.—2s. per gall.
Xylol coml.	2s. 3d. per gall.
Pure	3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	9d.—9½d. per gall. Few inquiries.
Middle Oil, Heavy, Standard Specification	6¾d.—9d. per gall. according to grade and district. Market very quiet.
Naphtha—	
Solvent 90/160	1s. 4d.—1s. 5d. Market steady.
Solvent 90/190	1s. 1d.—1s. 4d. Fair business, passing.
Naphthalene Crude—	
Drained Creosote Salts	£6—£6 10s. Demand falling off.
Whizzed or hot pressed	£9—£12 per ton. Little business.
Naphthalene—	
Crystals and Flaked	£16—£17 per ton.
Pitch, medium soft	52s. 6d.—57s. 6d. per ton. No export business at present. Plenty of inquiries for next season.
Pyridine 90/160	21s.—22s. per gall. Market less firm.
Heavy	12s.—12s. 6d. Market steady.

INTERMEDIATES AND DYES

Business in dyestuffs has been fairly good and has shown a little further improvement during the past week. Prices remain constant.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H	4s. 3d. per lb. 100% basis d/d.
Acid Naphthionic	2s. 4d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 1½d.—1s. 2d. per lb. Better demand at reduced prices
Acid Sulphanilic	9½d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	7¾d.—8½d. per lb. naked at works.
Aniline Salts	7¾d.—9d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 19/31° C.	4½d. per lb. Demand steady.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline	3s. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£75 per ton.
Diethylaniline	4s. 9d. per lb. d/d., packages extra, returnable.
Dimethylaniline	2s. 4d. per lb. d/d. Drums extra.
Dinitrobenzene	9d. per lb. naked at works.
Dinitrochlorbenzol	£84 10s. per ton d/d.
Dinitrotoluene—48/50° C.	8d.—9d. per lb. naked at works.
66/68° C.	1s. 2d. per lb. naked at works.
Diphenylamine	3s. per lb. d/d
Monochlorbenzol	£63 per ton.
β Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 4½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 4d. per lb. d/d.
Nitrobenzene	5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.

Nitronaphthalene	.. 11¾d. per lb. d/d.
p-Nitrophenol ..	.. 1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis
m-Phenylene Diamine	.. 4s. 2d. per lb. d/d.
p-Phenylene Diamine	.. 10s. 3d. per lb. 100% basis d/d.
R. Salt	.. 2s. 6d. per lb. 100% basis d/d.
Sodium Naphthionate	.. 2s. 5d. per lb. 100% basis d/d.
o-Toluidine ..	.. 8½d. per lb.
p-Toluidine ..	.. 3s. 6d. per lb. naked at works.
m-Toluylene Diamine	.. 4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The demand is steady for the small quantities required for home consumption, but export inquiry for larger bulk is wanting.

Acid, Acetic 80% B.P.	.. £47 per ton.
Acid, Acetyl Salicyclic	.. 3s. 3d.–3s. 5d. per lb. Value maintained.
Acid, Benzoic B.P.	.. 3s. 9d. per lb. Larger supplies available.
Acid, Boric B.P.	.. Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain. Prices reduced by £3 per ton.
Acid, Camphoric..	.. 19s.–21s. per lb.
Acid, Citric ..	.. 1s. 6½d. per lb., less 5% for ton lots. Market extremely firm. Upward tendency.
Acid, Gallic ..	.. 3s. per lb. for pure crystal. Market firmer.
Acid, Pyrogallic, Cryst.	.. 7s. per lb. for 1 cwt. lots. Market firm; increasing demand.
Acid, Salicylic ..	.. Prices quoted from 2s. per lb. down to 1s. 8d. for ton lots. Market still weak.
Acid, Tannic B.P.	.. 3s. per lb. Market quiet.
Acid, Tartaric ..	.. 1s. 1½d.—1s. 2d. per lb. less 5%. Better tone but not yet very active. Cheap offers of second hand parcels of foreign acid. Higher prices expected in view of firmness of raw materials.
Amidol	.. 9s. per lb. d/d.
Acetanilide ..	.. 2s. 3d. per lb. for quantity. Demand slow. Prices shaded to secure large orders.
Amidopyrin ..	.. 13s. 3d. per lb. Neglected. Stocks low.
Ammon. Benzoate	.. 3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	.. 12s. 6d. per oz. for English make.
Barbitone.. ..	.. 15s. per lb. Quiet market.
Benzonaphthol ..	.. 5s. 6d. per lb. Small inquiry.
Bismuth Salts ..	.. A steady market. Prices according to quantity:
Bismuth Carbonate	.. 12s. 9d.—14s. 9d. per lb.
„ Citrate..	.. 11s. 4d.—13s. 4d. „
„ Salicylate	.. 10s. 2d.—12s. 2d. „
„ Subnitrate	.. 10s. 9d.—12s. 9d. „
Borax B.P. ..	.. Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides— ..	.. Fluctuating market. Continental prices decidedly firmer.
Potassium ..	.. 11d. per lb.
Sodium.. ..	.. 1s. „
Ammonium ..	.. 1s. 1d. per lb.
Calcium Lactate..	.. Demand active. Good English make can be had from 1s. 7d. to 2s. 6d. per lb.
Chloral Hydrate	.. 3s. 7d.—3s. 9d. per lb., duty paid.
Chloroform ..	.. 2s. per lb. for cwt. lots. Very steady.
Creosote Carbonate	.. 6s. 6d. per lb. Little demand.
Formaldehyde ..	.. £57 per ton, *ex* works. English make.
Glycerophosphates—	Fair business passing.
Calcium, soluble and citrate free ..	.. 7s. per lb.
Iron	.. 8s. 9d. per lb.
Magnesium ..	.. 9s. per lb.
Potassium, 50%	.. 3s. 6d. per lb.
Sodium, 50% ..	.. 2s. 6d. „
Guaiacol Carbonate	.. 11s. per lb. for cwt. lots. Slightly cheaper.
Hexamine ..	.. 3s. 6d. per lb. for English make. Market quiet and steady.
Homatropine Hydrobromide	.. 30s. per oz.
Hydrastine hydrochlor	.. English make offered at 120s. per oz.
Hydroquinone ..	.. 4s. 3d. per lb. in cwt. lots. Foreign make.
Hypophosphites—	
Calcium ..	.. 3s. 6d. per lb., for 28-lb. lots.
Potassium ..	.. 4s. 1d. per lb.
Sodium ..	.. 4s. „
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 5d. per lb., according to quantity.
Magnesium Carbonate—Light Commercial	.. £36 per ton net.
Magnesium Oxide—	
Light Commercial	.. £75 per ton, less 2½%.
Heavy Commercial	.. £26 per ton, less 2½%.
Heavy Pure ..	.. 1s. 6d.—2s. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	.. 55s. per lb. Weaker.
Synthetic ..	.. 26s.—35s. per lb., according to quantity. English make. Steady demand.
Mercurials ..	.. Market firm.
Red oxide ..	.. 5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	.. 3s. 6d.—3s. 7d. „
White precip. ..	.. 4s. 7d.—4s. 8d. „
Calomel ..	.. 3s. 11d.—4s. „
Methyl Salicylate	.. 2s.—2s. 3d. per lb. for carboys. Not much demand.
Metol	.. 11s. per lb. British make.
Paraformaldehyde	.. 3s. per lb.
Paraldehyde ..	.. 1s. 4½d.—1s. 6d. per lb. in free bottles and cases. Better demand.
Phenacetin ..	.. 6s. per lb. Ample stocks available.
Phenazone ..	.. 7s. 3d. per lb. for cwt. lots. Quiet.
Phenolphthalein	.. 6s. 6d. per lb. Easier with supplies more plentiful.
Potass. Bitartrate—99/100% (Cream of Tartar) ..	.. 88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate ..	.. 1s. 10d.—2s. 2d. per lb.
Potass. Iodide ..	.. 16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.
Potass. Metabisulphite	.. 7½d. per lb., 1-cwt. kegs included.
Quinine Sulphate	.. 2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	.. 5s. 6d. per lb.
Saccharin.. ..	.. 63s. per lb., in 50-lb. lots.
Salol	.. 3s. 6d.—3s. 11d. per lb. Easier in sympathy with other salicylates.
Silver proteinate..	.. 9s. 6d. per lb.
Sod. Benzoate, B.P.	.. 2s. 9d. per lb. In steady demand for good qualities.

Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity. Firm in common with other citrates.
Sod. Hyposulphite—Photographic ..	.. £13 £15 per ton, according to quantity, d.d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	.. 16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt)	.. 77s. 6d.—81s. 6d. per cwt., according to quantity. Market quiet.
Sod. Salicylate ..	.. Market easier. Powder 2s. 2d. 2s. 6d. per lb. Crystal at 2s 5d.—2s. 8d. per lb. Flake 2s. 9d. 2s. 10d. per lb.
Sod. Sulphide—Pure recryst ..	.. 10d 1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£27 10s —£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Thymol	.. 15s 16s 6d. per lb for good white crystal from ajowan seed. Very firm and scarce

Camphor Oil ..	.. 75s. per cwt.	
Cananga Oil Java	.. 10s. 6d. per lb.	
Cinnamon Oil, Leaf	.. 6½d. per oz.	
Cassia Oil, 80/85%	.. 8s. 9d. per lb.	Cheaper.
Citronella Oil —		
Java 85/90% ..	.. 6s. per lb.	
Ceylon	.. 3s. 9d. per lb.	
Clove Oil . ..	. 7s. 3d per lb.	Cheaper.
Eucalyptus Oil 70/75% ..	2s. 2d. per lb.	
Lavender Oil		
French 38/40% Esters	27s. 6d. per lb.	
Lemon Oil ..	.. 3s. 2d. per lb.	
Lemongrass Oil	.. 3d. per oz.	
Orange Oil, Sweet	.. 13s. 9d. per lb.	
Otto of Rose Oil		
Bulgarian ..	.. 27s. 6d. per oz.	
Anatolian ..	.. 23s. 6d. per oz.	
Palma Rosa Oil	.. 19s. per lb.	
Peppermint Oil—		
Wayne County	.. 20s. 9d. per lb.	
Japanese ..	.. 15s. 6d. per lb.	
Petigrain Oil ..	.. 10s. per lb.	
Sandal Wood Oil—		
Mysore	.. 26s. 6d. per lb.	
Australian ..	.. 21s. per lb.	

PERFUMERY CHEMICALS

Acetophenone	12s. 6d. per lb.		
Aubepine	14s 6d.	,,	
Amyl Acetate	2s. 9d.	,,	
Amyl Butyrate	6s. 9d.	,,	
Amyl Salicylate	3s. 3d.	,,	
Anethol (M.P. 21/22° C)	4s. 6d	,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s 10½d	,,	Cheaper.
Benzyl Alcohol free from Chlorine . ..	2s 10½d.	..	Cheaper
Benzaldehyde free from Chlorine	3s. 6d.	,,	
Benzyl Benzoate ..	3s. 6d	,,	
Cinnamic Aldehyde Natural	15s. 6d.	,,	
Coumarin	20s	,,

PATENT LIST

The dates given in this list are, in the case of Applications for Patents, those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition not later than Aug. 18th, they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. on July 3rd.

I.—Applications

Dawson. Evaporators. 13,948. June 10.

Kirschbraun. Manufacture of emulsions 14,054. June 10.

Rieber and Veruert. Furnaces. 14,461. June 11. (Ger., 19.11.23.)

I.—Complete Specifications Accepted

7230 (1923). Internationale Bergin-Compagnie voor Olie en Kolen Chemie, and Loffler. Apparatus for indicating liquid levels in high-pressure stills or other vessels. (216,959.)

13,331 (1923). Futers, and Semet-Solvay and Piette Coke Oven Co., Ltd Separation of excess liquid from subdivided solid materials. (217,025.)

17,293 (1923). Schueler. Centrifugal separators. (217,065.)

1303 (1924). Ellis. Ball crushing mills. (217,154.)

4631 (1924). Priest. Refractory coverings for the shafts, flues, and other passages of furnaces, kilns and the like. (217,160.)

II.—Applications

Aktiebolaget Separator. Treating materials containing paraffin. 14,237. June 12. (Ger., 28.6.23.)

Bullinger, Melhardt, Weisz, Winternitz, and Zeroe Refining mineral oils etc. 14,246, June 12. (Austria, 14.7.23.)

Koppers Co. Elimination of hydrogen sulphide from fuel gases etc. 14,049. June 10. (U.S., 6.6.24.)

Koppers Co. Purification of gases etc. 14,068. June 10. (U.S., 6.6.24.)

II.—Complete Specifications Accepted

3687 (1923). Demoulins and Garner. Purification of hydrocarbons, particularly lighter petroleum fractions (216,918.)

5442 (1923). Linker. Manufacture of high quality fuel from raw peat. (216,921.)

5956 (1923). Lamplough. Treatment of hydrocarbon oil vapours. (216,922.)

6639 (1923). Wood, Jenkins, and Minerals Separation Ltd. Agglomeration of coal. (216,948.)

14,710 (1923). Fuel Recovery Syndicate, Ltd., and Bowater. Distillation of fuels. (217,041.)

24,180 (1923). Rude. Process of and apparatus for the carbonisation of solid fuel. (204,718.)

III.—Application

Stewart and Walmsley. Aromatization of tars. 13,999. June 10.

IV.—Complete Specification Accepted

8120 (1923). Carpmael (Bayer & Co.). Manufacture of azo dyes. (216,971).

V.—Applications

Bacon, and I. P. M. Syndicate, Ltd. Treatment of fibrous cellulose for production of hydrated derivatives. 14,411. June 14.

Baldinger. Obtaining fibres from leaves of agaves etc. 14,052, 14,053. June 10.

Boorne. Product of cellulose etc. fibrous materials. 14,042. June 10.

Ubbelohde. Treating fibres. 14,269. June 12.

V.—Complete Specifications Accepted

9052 (1923). Plauson's (Parent Co.), Ltd. (Plauson). Manufacture of paper. (216,923.)

6882 (1923). Cross and Englestad. Manufacture and applications of new lignone derivatives. (216,949.)

11,008 (1923). Levy. Production of artificial filaments. (217,003.)

17,468 (1923). Courtaulds, Ltd., and Cross. Manufacture of threads etc. from viscose. (217,068.)

29,067 (1923). Stewart and Brown. Digesters used in paper-making etc. (217,130.)

VI.—Application

Chem. Fabr. Griesheim-Elektron. Manufacture of mixtures for dyeing or printing textiles. 14,179. June 11. (Ger., 11.6.23.)

VI.—Complete Specifications Accepted

6196 (1923). Pattison (Tomlinson and Thomas). Apparatus for treating fibrous materials with liquids or gases. (216,929.)

6481 (1923). Bloxam (Land Akt.-Ges.). Obtaining new effects on animal fibres. (216,940.)

VII.—Applications

Belton and Budde. Adsorption of sulphur dioxide and hydrogen sulphide. 14,219. June 12.

Cosmic Arts, Inc. Treatment of natural alkaline salts. 14,273. June 12. (Belgium, 12.6.23.)

Deutsche Gold und Silber-Scheideanstalt vorm. Roessler, and Liebknecht. Manufacture of hydrocyanic acid. 14,458. June 14.

Suida. Manufacture of concentrated acetic acid. 14,281 and 14,341. June 12 and 13. (Austria, 26.6.23.)

VII.—Complete Specification Accepted

19,982 (1923). Ozon-Technik Akt.-Ges. See XI.

VIII.—Applications

Stettiner Chamotte-Fabrik Akt.-Ges. vorm. Didier. Manufacture of retractory bricks etc. 14,259. June 12. (Ger., 21.6.23.)

VIII.—Complete Specification Accepted

1631 (1924). Priest. See I.

IX.—Application

Arnot. Adhesives and cements. 14,343. June 13.

IX.—Complete Specifications Accepted

7328 (1923). Butler and Popham. Bituminous and like compositions. (216,911.)

6974 (1923). Broadfoot and Sons, Ltd., and Robertson. Cement and filling material. (216,951.)

X.—Applications

Gelsenkirchener Bergwerks-Akt.-Ges. Carbonization of ores etc. 14,462. June 14. (Ger., 24.1.24.)

Harada. Manufacture of aluminium alloy. 14,257. June 12.

Oppermann. Refining and freeing bubbles from molten metals. 14,111. June 11.

Western Electric Co., Ltd. (Western Electric Co., Inc.). Metallic compositions. 14,128. June 11.

X.—Complete Specifications Accepted

19,605 (1923). Electrolytic Zinc Co. of Australasia, Ltd. Treatment of zinc-bearing ores etc. (201,918.)

19,606 (1923). Electrolytic Zinc Co. of Australasia, Ltd. Electrolytic recovery of zinc from zinc-bearing ores etc. (202,299.)

XI.—Applications

Monnot. Production of electrodes for alkaline storage batteries. 14,371. June 13.

Shearman. Apparatus for electrification of gases. 14,131. June 11.

Western Electric Co., Ltd. (Western Electric Co., Inc.). Insulating-materials for submarine cables etc. 14,129. June 11.

XI.—Complete Specifications Accepted

11,093 (1923). Pepper. Electric batteries. (217,004.)

19,606 (1923). Electrolytic Zinc Co. of Australasia, Ltd. See X.

19,982 (1923). Ozon-Technik Akt.-Ges. Apparatus for electrically producing ozone. (201,938.)

29,387 (1923). Chloride Electrical Storage Co. (Electric Storage Battery Co.). Electric accumulators. (217,131.)

XII.—Applications

Goonewardene and Julien. Manufacture of desiccated nuts and oil from coconuts etc. 14,174. June 11.

Kirschbraum. 14,054. See I.

XII.—Complete Specifications Accepted

33,226 (1922). Legradi. Manufacturing soap poor in water. (202,263.)

32,623 (1923). Calderwood, Webb, and Reibl. See XIII.

XIII.—Applications

Mehta. Manufacture of resins. 14,244. June 12. (U.S., 12.6.23.)

Mulligan. Paints and washes. 14,328. June 13.

XIII.—Complete Specifications Accepted

6975 (1923). Broadfoot and Sons, Ltd., and Robertson. Plastic material for the production of moulded articles. (216,952.)

15,769 (1923). Davidson. Fraud-preventing ink. (217,053.)

32,623 (1923). Calderwood, Webb, and Reibl. Preparation of oils for varnishes, printing inks, paints, linoleums, and the like. (217,150.)

XIV.—Applications

Churchill. Vulcanising material. 14,394. June 13.

Mann. Treatment of rubber latex. 14,312. June 13.

XV.—Complete Specification Accepted

6976 (1923). Broadfoot & Sons, Ltd., and Robertson. Adhesive. (216,953.)

XVII.—Complete Specification Accepted

8870 (1923). Brunn. Process for the production of phosphoric derivatives of inositol. (216,982.)

XIX.—Applications

Roberts. Food products. 14,102. June 11.

Westaway. Treating and preserving cream etc. 14,445. June 14.

XIX.—Complete Specifications Accepted

13,621 (1923). Cuthbertson. Process for preserving meat. (217,028.)

21,843 (1923). Bley. Preserving food. (217,103.)

25,000 (1923). Cuthbertson. Preserving fruit and vegetables. (217,117.)

XX.—Applications

Chem. Fabr. vorm. Sandoz. Manufacture of cardiac glucoside of Bulbus scillæ. 14,046. June 10 (Switz., 7.6.23).

Coke and Maxted. Oxidation of cyclic bodies. 14,115. June 11.

Desborough, Knight, and Thomson. Nitration of materials. 14,144. June 11.

Marks (Carbide & Carbon Chemicals Corporation). Processes of making alkyl chlorides. 14,077. June 10.

XX.—Complete Specifications Accepted

8715 (1923). Medical Research Council, and Dudley. Manufacture of a purified form of insulin. (216,978.)

15,634 (1923). Chem. Fabr. vorm. Sandoz. Manufacture of the cardiac glucoside of Bulbus scillæ. (199,400.)

31,991 (1923). Comp. Nat. de Mat. Colorantes et de Prod. Chimiques. Manufacture of perylene. (208,722.)

XXI.—Complete Specification Accepted

8545 (1923). Bolton, and Cavendish's, Ltd. Fixing-solutions for photography. (216,976.)

XXII.—Application

Desborough and others. 14,144. *See* XX.

XXIII.—Application.

Boothman, and Kershaw & Co. Viscometers. 13,991. June 10

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35 Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department, and quoting the specific reference number:—*Argentina:* Silk, (722 and 723); *Belgium:* Leather, skins, varnish, (709); *British India:* Steel, copper, (The Director-General, India Store Department, Branch No. 10 Belvedere Road, Lambeth, S.E. 1); *Canada:* Steel, (704); *Greece:* Metals, building materials, (712); *Netherlands:* Glassware, (713); Iron, (714); *South Africa:* Paper, (708).

Trade Information

Fuel Economy.—At the Convention of the District Engineer Representatives attached to the Feed Water Specialists Company, held in Liverpool from June 10 to 13, the Annual Dinner took the form of a send-off to the Manager, Mr H. W. Bannister, who is now on a voyage to the United States to obtain further data for securing economies in steam raising, so that still greater services will be rendered to steam users all over the world in the treatment of boiler-feed water. Mr. W. H. Crowe, of the Andrew Maxwell Co., referred to the appreciation by steam users of the research in colloidal chemistry carried out under the direction of Mr. Bannister. The treatment of each set of boilers, or even one boiler of a battery, made the service of the district engineers of particular value, whilst the reduction of intricate laboratory tests to the point of simple demonstration enabled works' managers and superintendent engineers to see at their own desks, within ten minutes, how the adoption of colloidal principles led to increased power at lower fuel and repair costs.

The Tully Gas Plant in Canada.—The City Council of Belleville, Ontario, Canada, has decided to adopt the recommendation of the special committee investigating the Tully Gas Plant, by which the plant will be accepted by the city. The special committee reported: (1) That the plant is capable of producing 45,000 cb. ft. of 450 B.Th.U. gas per ton of coal, with an oil consumption of less than 1½ gallon per 1000 cb. ft. of gas. (2) That one man per shift will operate the plant with assistance for clinkering every 24 hours. (3) That the plant as far as was possible for the Committee to ascertain, lives up to the guarantees of the Tully Gas Plants, Ltd. (4) That since the Tully system has been installed the Government heat tests of the gas have ranged from 458 to 484 B.Th.U.'s. (Government standard being 450 B.Th.U.'s.) The committee further said it felt assured that the installation of the Tully system was wise and that the Gas Department would now be on a profitable basis.

Smokeless Fuel in Glasgow.—The Glasgow Corporation Gas Department has decided to erect a plant utilising the Maclaurin process for producing smokeless fuel. The chief feature of the process is the producer, which is built by Messrs. Blair, Campbell and McLean, Ltd., of Govan, Glasgow. This low-temperature producer is internally heated only and supplies gas ranging from 140 to 350 B.Th.U. per cb. ft., according to whether it is worked for complete gasification, smokeless fuel, or metallurgical coke. The low cost of the gas makes the process very suitable for heating retorts, but the main object of the plant to be installed in Glasgow for carbonising 35,000 tons of coal annually, is the production of smokeless fuel.

Pulverised Fuel.—It is announced that the Birmingham Corporation has decided to install the Lopulco system of pulverised fuel on six boilers in the Nechells power station, instead of the mechanical stoker equipment previously ordered. As there is no room for the ordinary arrangement of coal bunker, drier, pulveriser and separator independently for each boiler, a separate pulveriser house will be erected on the other side of a canal by the boilerhouse, and the pulverised fuel will be blown across through narrow-bore pipes under 40 to 50 lb. pressure.

A. F. Craig & Co., Ltd., Engineers, Paisley, announces that their London office will be moved on June 24 from 12, Old Jewry Chambers, E.C. 2, to Abbey House, 2-8, Victoria Street, Westminster, S.W. 1.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 43 NEW SERIES LONDON, MAY 2, 1924 No. 18

EDITORIAL

OUR editorial in last week's issue was written before we had seen the letter from Dr. Fritzsche, which is printed in this number. It therefore gives us considerable satisfaction to find that he is in agreement with us in believing that a better understanding will be founded on a basis of truth—not on a basis of untruth and hypocrisy. We in this country have but little knowledge of what took place in East Prussia; our own newspapers and our principal Government publications naturally dealt mainly with those portions of the world in which British troops were engaged. Dr. Fritzsche is mistaken in thinking that we in this country approve of any actions in East Prussia not in accordance with the so-called rules of civilised warfare. We are in entire ignorance of these breaches and if any occurred we are confident that the vast majority of our people regret them. We see no reason why Dr. Fritzsche and the German men of science should not equally regret any breaches which occurred in France and in Belgium. It was the belief that the German men of science approved of what was done there, that it was well-merited, that inspired our editorial comments. Dr. Fritzsche will render a service to the cause of truth if he will disclose to us details of the documents he refers to as being concealed by the Allied Governments. Have they been published? When, and where? We do not attach such importance to the individual who has the singular brain referred to by Dr. Fritzsche. But many of us in this country have come across a number of Germans who before the war expressed their belief that the Germans represented a higher degree of civilisation than the British and that the war which they foresaw would come, would establish this fact. We do not attach great importance to this, other Germans were more sensible. As to Chauny we are certain that Dr. Fritzsche does not consider that Germany should adopt as her standard, the standard of Russia in East Prussia. As a true friend of humanity can he not regret that Chauny was destroyed, not by the ordinary destruction of artillery in a time of fighting, but in the way it was? As we write these notes we receive with the *Chemiker Zeitung* a copy of Kladderadatsch with some caricatures of no specially refined type. We wonder why the German men of science send these unscientific publications to their foreign subscribers. Is it to convince us of the unreasonable ways of the French or of those of the Berlin Town Council. What singular ideas prevail of this sort of propaganda! Does Dr. Fritzsche think the circulation of this document makes a very favourable impression in foreign countries? We suppose that in all probability Dr. Fritzsche has as little knowledge of Chauny and Louvain as we have of East Prussia. This *Journal* is no place for the elucidation of matters of history. Knowing nothing of East Prussia, but knowing the sort of thing that occurs in war, we make no effort to justify what took place there. Can Dr. Fritzsche believe that things happened in France and Belgium that he would not justify? It is in respect of these two countries that the difficulty is the greatest.

* * *

We have received from Professor Noyes a further communication and from some other correspondents letters which lack of space compels us to hold over until next week. It seems to us that we shall by then have sufficiently ventilated this matter for the present. English chemists are already visiting Germany and a few German chemists come to this country; we suppose that no one expects or desires that the gulf which at the moment separates the French and the Germans will continue indefinitely; already there are signs of a possible general European settlement which will diminish some of the ill-feeling which now exists. That settlement may be so satisfactory that a period of hostility will be replaced by one of neutrality and that again by one of friendliness. We suppose that every chemist hopes for this and that they will all, whatever nationality they possess, cheerfully and gradually drift into a more placid state of mind. Nothing is so harmful as the feeling of nursing our wrath to keep it warm. The views expressed in this *Journal* are of some interest as showing and even to some extent defining points of view which will be gradually modified or abandoned, not by the individuals who now hold them, but by the average chemist who desires the international unity of science and the complete dissociation of chemistry and politics.

POLITICAL PLATFORM FOR THE INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY

By Prof. W. A. NOYES

Germans and Austrians have been excluded from the Union for political reasons. If this is to continue the Union should adopt some political platform as the basis for adherence to the Union. Consciously or unconsciously, the reason why Frenchmen are unwilling to see Germans admitted is because they believe that Germany is preparing for another war, and that German chemists are in sympathy with such a purpose. With this in mind, the proper platform for the Union would be :—

1. War under modern conditions is intolerable, and must be avoided.
2. Nations adhering to the Union must agree that, in the future, they will settle all their differences by diplomatic means, or through the World Court.

As between Germany and the Allies the following logical consequences seem to follow.

Germans should agree :—

1. That Austria was wrong when she refused to submit her quarrel with Servia to The Hague, and Germany was wrong in supporting her.
2. That as soon as Germany has been admitted to the League of Nations, and to equal terms in the World Court, all questions of difference between Germany and any of the Allies shall be submitted to the World Court for decision, and shall not be used as a basis for another war.

The Allies should agree :—

1. That the question of the legality of the occupation of the Ruhr should be decided by the World Court.
2. That, in the future, additional German territory shall not be occupied, except in support of a decision of the World Court.

I am very far from thinking that any political platform for the Union is desirable. A political basis for membership seems to me just as undesirable as a religious basis would be. But if a political basis is to be continued, it should be clearly defined and applied impartially, instead of resting, as it does now, on the misunderstanding, hatred and suspicion which have grown from the war.

So long as either the Allies or Germans insist that the mistakes and wrongs of the last 60 years have been all on one side, there can be no peace, and each will continue to prepare for another war. When each is willing to admit that there has been some wrong on their own side, and when each is willing to leave to a less partisan coming generation a more accurate decision about *relative* guilt, and, above all, when each is willing to agree that future differences must be decided by some legal process and not by war, there will be some hope of a permanent peace.

The political leaders of Germany and of the Allies seem to be preparing for peace on the basis of the report of the Commission of experts. Is it not possible for the scientific men of the world to *lead* in ways of peace instead of merely following the financiers and politicians ?

THE PHENOMENA OF ROTATION DISPERSION

By Prof. T. S. PATTERSON

A discussion on rotation dispersion at the Chemical Society reported in *Chemistry & Industry* of March 28, (p. 331) prompts me to the following remarks on the subject.

It may perhaps be said that the purely empirical period in the development of our knowledge of optical activity came to an end in the year 1913. I believe I was the first (*J.C.S.*, 1913, **103**, 145) to generalise the subject by correlating and discussing from a single point of view all the different factors which influence the rotation of a compound—its chemical constitution, the effect of temperature, the influence of solvents and the influence of the refrangibility of the light used. A few months later (April) Armstrong and Walker (*Proc. Roy. Soc.*, [A] **88**, 392), studying the behaviour of fructose, assumed its rotation to be due to the superposition of the rotations of two iso-dynamic forms of this compound, the rotation of each form being unaffected by other factors such as temperature change or the influence of solvents, thus applying to fructose a suggestion similar to that made by Arndtsen (*A. ch. ph.*, 1858, [3], **54**, 421) regarding tartaric acid, which in turn depended upon an observation of Biot's that the dispersion of tartaric acid could be imitated by the behaviour of a mixture of turpentine and camphor. They conceived further the idea of plotting their results upon what they called a characteristic diagram, and were able to show that the data which had been obtained from various other active compounds lay also along straight lines on characteristic diagrams.

In a similar manner Pickard and Kenyon found that the majority of their data also fitted in a most interesting manner on to characteristic diagrams, and, on the whole, they appeared to adopt as an explanation of the fact, the view put forward by Armstrong.

Lowry has been a very ardent advocate of Arndtsen's hypothesis, and, placing his faith in an expression suggested by Drude, attempted to distinguish between what he calls simple, complex and anomalous rotatory dispersion, a point which will be referred to further on.

In three papers published in 1916 (*J.C.S.*, **109**, 1139, 1176, 1204) I carried the generalisation of this subject a stage further, pointing out from purely experimental considerations that the study of temperature rotation curves leads, without the introduction of any theory at all, to what is really the fundamental significance of the characteristic diagram, namely, the fact that, for related series of compounds, the common value of the rotation for two different colours of light is independent of other factors, such as temperature, solvent and—within limits—constitution, and on this account I suggested the idea of a rational zero from which dispersion coefficients should be calculated. I also subjected (l.c., p. 1204) Lowry's views to some criticism, pointing out their complete insufficiency to account

for the observed phenomena. This criticism met with the approval of other authors, (P. F. Frankland and Garner, *J.C.S.*, 1919, **115**, 638, 639; H. M. Dawson, *Chem. Soc. Ann. Reports*, 1917, **13**, 25), and it is very satisfactory to find, from his recent letter in *Chemistry & Industry*, April 4, p. 365, that Dr. Pickard now also supports the views which were put forward by me in 1916.

To my criticisms, however, Lowry has not made any attempt to reply and it can only be regarded as remarkable that after his views had been seriously impugned he has republished them in a paper with Austin (*Phil. Trans.*, 1922, [A] 222, 249), an abstract of which appeared in *Nature* of April 8, 1922, p. 447.*

I propose therefore to restate the main difficulties to which Lowry's hypothesis gives rise.

In the first place it has been found in recent years that in a great many cases, both for homogeneous active substances and for active substances in solution, the rotation rises with increase of temperature to reach a maximum value, and then falls again, or conversely, falls to a minimum value and then rises again. According to Lowry, the change of rotation with change of temperature is due to alteration in the relative proportions of dynamic isomerides assumed to be present. It seems clear that, unless one makes assumptions so gratuitous as to render all argument impossible, and to remove the matter to a sphere where faith takes the place of reason, this theory cannot account for the observed behaviour. To this very important point Lowry makes no reference whatever.

In the second place I pointed out that the behaviour of nitrocamphor in regard to mutarotation and other rotatory phenomena is widely at variance with Lowry's hypothesis. In such a substance as ethyl tartrate, to take a definite example, the specific rotation in 10 per cent. aqueous solution is +26°, in 10 per cent. ethylene bromide solution it is —11·5°. According to Lowry this is due in these two solvents to a difference in the relative proportions of two dynamic isomerides of ethyl tartrate, these isomerides having unequal rotations. Now, in the cases of such substances as glucose or fructose which show mutarotation, the isodynamic change takes place slowly whereas solvent influence, as in the above case, is an instantaneous phenomenon. Lowry merely begs this question by first assuming the changes to take place and adding "whatever the nature of these chemical changes may be, they must proceed to equilibrium with very great rapidity, since even the most careful experiments have failed to detect any lag in the adjustment of rotatory power in the tartaric esters when conditions have been altered." (*Phil. Trans.*, l.c., p. 259, see also *J.C.S.*, 1915, **107**, 1177; 1916, **109**, 1214.) This must surely be one of the strangest arguments ever put forward in a scientific paper, the failure of experiments undertaken to test an hypothesis being regarded not merely as confirmation, but even as amplification of it. This same test would not only reveal the existence of mutarotation in every substance exhibiting anomalous rotatory dispersion, but also in any other substance whatever to which one might choose to apply it.

In favour of their view Lowry and Austin submit the chemical evidence that, in the case of nitrocamphor, isomerides in equilibrium actually exist and "that their behaviour is in accordance with that which must be postulated for the 'two kinds of optically active molecules' assumed by Arndtsen." (*Phil. Trans.*, l.c., 260.) In view of the importance which the behaviour of nitrocamphor thus assumes, I may point out again that the effect of mutarotation and the effect of solvent influence in nitrocamphor can, from Lowry's own investigations, be clearly shown to have no connexion with each other.

If a 5 per cent. solution of the *a* form of nitrocamphor in benzene is examined, the rotation is found to alter with lapse of time. But by extrapolation from these results, one can obtain the value —125° as the initial rotation for this solution, that is, the rotation of one definite form of nitrocamphor before it has commenced to change into the other form. In exactly the same way the initial rotation in xylene is found to have the value —99°, and in chloroform the value 27°. These are the values of one and the same form of nitrocamphor uninfluenced by mutarotation; the values before mutarotation comes into play. It is therefore apparent that *a*-nitrocamphor shows a very marked solvent influence, and it is also obvious that this solvent influence is quite independent of the ordinary mutarotation of the nitrocamphor, and since mutarotation and solvent influence can be thus clearly differentiated from each other, it follows that they have no necessary connexion. In exactly the same way it can be shown that the rotation of pure *a*-nitrocamphor before mutarotation occurs, varies with concentration in benzene, and this again entirely excludes dynamic isomerism and brings nitrocamphor into line with ethyl tartrate and other similar substances. Since therefore the behaviour of nitrocamphor when the influence of mutarotation has been eliminated is in all respects analogous to the behaviour of ethyl tartrate, there is clearly no case for the suggestion that mutarotation is the cause of the solvent effects observed with ethyl tartrate. Thus the behaviour of nitrocamphor instead of being a support of Lowry's hypothesis, affords perhaps the strongest evidence which can be brought against it.

Nevertheless, Lowry and Austin find it difficult to resist "the conclusion that tartaric acid, like nitrocamphor, can exist in two forms and yields two types of derivatives, and that the presence of these two types is responsible for the complex rotatory dispersion of the acids and of some of its derivatives." (*Nature*, l.c., 450.) Lowry, somewhat prematurely, even suggests formulæ for these isomers

* In the account of this paper which appeared in *Nature*, [illegible], Lowry and Austin make the mistake of attributing to Biot (1812) the explanation of the sequence of beautiful colours produced by the interposition of quartz plates cut perpendicular to the axis, between a polariser and an analyser at extinction. This phenomenon was, in fact, not only discovered by Arago in 1811 but fully understood and explained by him. Biot merely developed—with characteristic verbosity—the discovery of Arago.

of tartaric acid, Lowry and Burgess stating (*J.C.S.*, 1923, **123**, 2118) that "after ten years search the co-ordination of the hydrogen atom has at last provided a satisfactory formula for the elusive laevo form of the acid."

Lowry and Austin (*Phil. Trans.*, l.c., 259) say that, "in recent years this extreme sensitiveness has been regarded by many writers as an inherent quality of the physical property of optical rotatory power, but all the new evidence goes to show that Biot was right in attributing it to chemical change in the optically active liquid."

But the whole of the evidence upon which Lowry and Austin rely consists of :—1. The experiment cited above, by Biot, (A. ch. ph. 1852, [3], **36**, 462) regarding which it need perhaps only be remarked that the optical behaviour of a mixture of turpentine and camphor has not been investigated by modern methods, it being therefore by no means certain that it is analogous with that of such a substance as tartaric acid. Further, this part of the evidence would seem to assume that both of the substances, turpentine and camphor, have so-called simple and normal rotation dispersion. It appears, however, to be the case that both of the substances on which this proof depends, themselves show anomalous rotation dispersion, a fact which seems sufficient to invalidate the whole argument. 2. The behaviour of nitrocamphor, which, as explained above, tends exactly in the opposite direction, and 3, their mathematical application of Drude's expressions to rotation-dispersion curves, which last presumably constitutes "the new evidence" as there is nothing more. This "mathematical evidence" consists in assuming that the relationship between rotation and wave length ought to be represented by the expression suggested by Drude—$a = \frac{k}{\lambda^2 - c}$. The statement that certain data can be represented by a Drude expression containing only one term sounds perhaps more simple than it is, for this expression represents a cubic curve and contains two arbitrary constants. Nevertheless, if values for k and c can be found to fit the experimental data, Lowry calls the dispersion simple, and assumes that the active substance present is homogeneous. If suitable constants cannot be found the expression is altered to $a = \frac{k_1}{\lambda^2 - c_1} + \frac{k_2}{\lambda^2 - c_2}$ which is an expression of the *fifth* degree containing *four* arbitrary constants. Considering the complexity of the expression it is not surprising that it can be adapted to fit most rotation-dispersion curves. If it does fit Lowry calls the dispersion, according to circumstances, anomalous or complex, and maintains that since there are two Drude terms there are two dynamic isomerides present, the discovery of which "is a fascinating problem which still awaits investigation." (*Nature*, l.c., 450) The rotation-dispersion of quartz, as appears from Lowry's work, can only be represented by a Drude expression containing three terms. Presumably therefore the discovery of three dynamic isomerides of quartz is another fascinating problem for the future.

All these "theories" about rotation dispersion seem to indicate a strange neglect of what appears to me, at least, to be the chief fruit of many years of investigation. According to Lowry's way of looking at the subject, not merely each particular substance, but each particular substance in all the infinite number of different circumstances in which it might be placed by change of temperature, change of solvent, and change of concentration, must be regarded as a separate case almost completely unrelated to each other, whereas, in fact, the experimental results obtained by Frankland, Lowry, Pickard and Kenyon, myself, and others, regarded from a broader point of view, show a most remarkable uniformity and allow of a very wide generalisation. In the accompanying figure is shown a characteristic

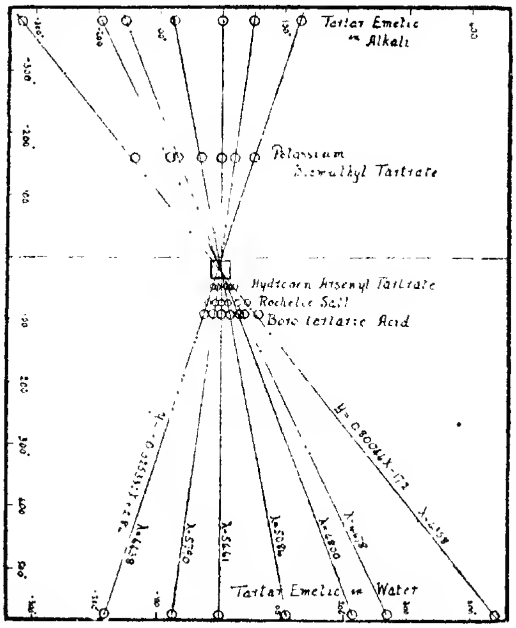

diagram embracing Lowry and Austin's results, the diagram being constructed according to the method suggested by me (*J.C.S.*, 1916, **109**, 1181) Rotation values for mercury green are plotted along the horizontal axis which is therefore taken as the reference line, and vertically above or below these (according to sign) there are plotted the corresponding differences between these rotations and those for other colours of light.

The data represented by the diagram vary from the value $[M]^{20}_{4358} = 1015{\cdot}8$ for tartar emetic in 5·32 per cent. aqueous solution to $(M)^{20}_{4358} = -702$ for tartar emetic in alkaline solution. Since the highest values of the rotation of tartaric acid itself is only 27°, it is impossible to make the data for tartaric acid visible along with the others on a diagram of practicable dimensions. It will be seen, however, that the data of Lowry and Austin for tartar emetic, potassium tartrate, Rochelle salt, borotartaric acid and potassium bismuthyl tartrate

all in aqueous solution and for tartar emetic in alkaline solution lie very nearly along straight lines in the diagram. The values for tartaric acid lie within the region marked by a square, the region within which anomalous rotation dispersion is most obvious. In spite of the fact that, according to Lowry and Austin, the dispersion of tartar emetic in aqueous solution as well as in excess of alkali is both simple and normal, whilst that of tartaric acid is highly anomalous the data for them all appear to fit on to one diagram. On account of the difference of scale this is most easily shown by calculation. In the figure, the line which joins the point representing the rotation of tartar emetic in water ($p = 5·32$) for violet light, and that representing the corresponding rotation for tartar emetic of a similar concentration in the presence of excess of alkali, has the equation $y = 0·80044X - 17·2$, whereas that joining the two points representing the rotations for the cadmium line 6438, has the equation $y = 0·325222X + 2·84$. These two lines intersect one another at a point whose co-ordinates are (+17·8, —2·92): at this point the rotation for these two colours would be equal and would have the value +14·88°, the corresponding value for mercury green being +17·8°. By constructing a separate diagram on a much larger scale for tartaric acid, the cadmium red and mercury violet lines are found to intersect at the value +13·19°, a point which can, of course, actually be realised in practice, and which is astonishingly close, considering the circumstances, to the 14·88 which is derived from the tartar emetic curves. Is it not a very significant fact that the highly "anomalous" rotation dispersion of tartaric acid can be calculated thus closely from the data, so very different in degree, of tartar emetic in water or in alkaline solution, considering the fact that in both the latter cases, the rotation dispersion is "normal" and simple." Surely, therefore, the whole lesson of the characteristic diagram is that the dispersion of all these substances for these two colours of light should be calculated with reference to this particular point +13·19°,—the rational zero for these two colours.

Similarly, of course, the dispersion ratio for mercury violet and mercury green should be calculated from the point of intersection of these two lines which, by calculation from the data for tartar emetic, is +17·8°, and from the diagram for tartaric acid is 19·7°. In the table in the next column dispersion coefficients for $\frac{Hg_{gr}}{Hg_{v}}$ calculated (1), by the ordinary method, and (2) from the rational zero (19·7) are compared.

Whilst the ordinary dispersion co-efficient varies between 0·2795 and 1·869, the rational dispersion coefficient only varies between 1·709 and 1·861, and embraces a considerable number of different substances under different circumstances. This procedure seems to summarise Lowry and Austin's work very much more simply than their own, since the latter involves the elimination of some fifty or sixty arbitrary constants.

This question seems analogous to that of the specific heats of the elements. When Dulong and Petit found that, for the most part, the atomic weight of an element multiplied by its specific heat gave a constant, they simply adopted, without theorising on the subject at all, what appeared to be a suggestion made by nature itself. In the present instance nothing could be clearer than that, for a set of chemically related compounds, the ratio of the rotation for a given colour of light to that for some other colour of light ought to be calculated with reference to the common rotation value for these two colours—with reference to the rational zero. When such a regularity as is shown in the table can be introduced amongst a heterogeneous collection of data like these, surely the obvious conclusion ought to be adopted whether or not a theoretical "explanation" connecting the phenomena with hypothetical absorption bands or problematical electrons can be offered. For after all, what this phenomenon requires is investigation rather than "explanation."

DISPERSION COEFFICIENT OF DERIVATIVES OF TARTARIC ACID

Organic Chemistry Department,
University of Glasgow
April 9, 1924

The death is announced of Prof. Siegmund Gabriel, for many years director of the organic division of the Chemical Institute of the University of Berlin, and author of numerous researches on the synthesis of organic compounds, especially of phthalic acid derivatives, and amines.

THE HOLMBOE ELECTROLYTIC HYDROGEN GENERATOR

By MARC HANSSEN
Chief Eng., Fredrikstad, Norway

The use of hydrogen in the chemical industry for the hydrogenation of oils and fats and in various synthetic processes as in the manufacture of precious stones, has been considerably increased during the last ten years, and it seems as if the successful development of many important branches of the chemical industry will, to a large extent, depend on the safe production of large quantities of pure and cheap hydrogen.

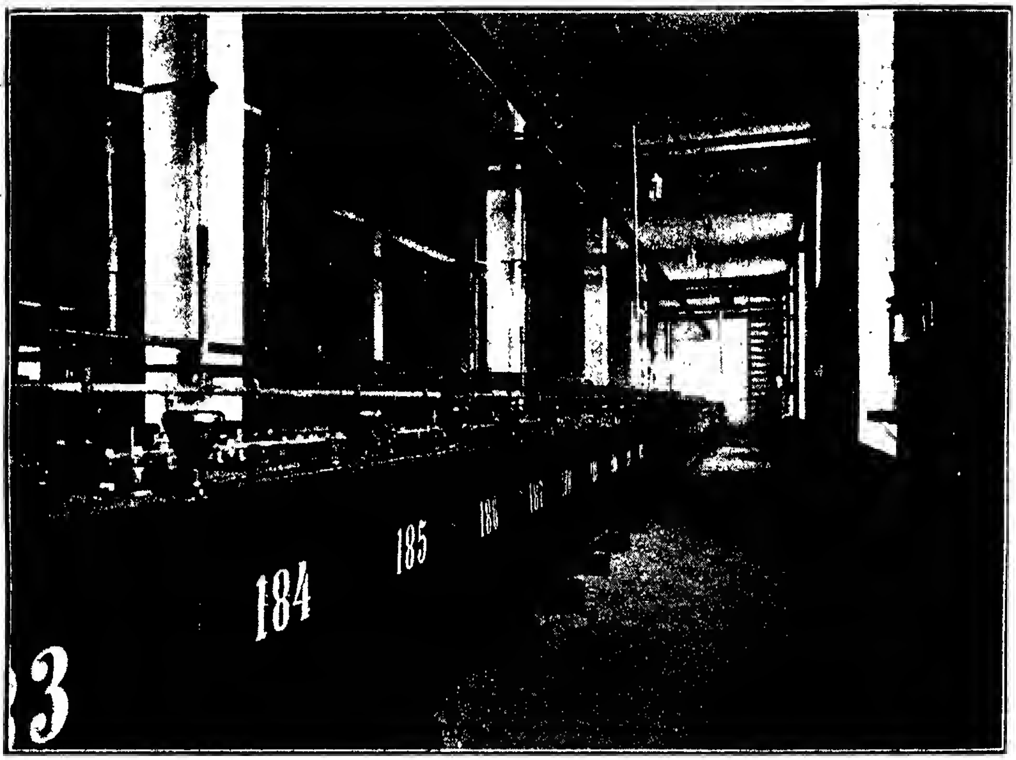

Fig. 1

The purity of the gas is of the greatest importance and it is generally required that hydrogen shall have a purity of 100 per cent., and be free from moisture. The only process, which up to the present has been able to comply with this requirement, is the electrolytic process, as most of the electrolytic plants can produce hydrogen with a purity close to 100 per cent., the impurities being oxygen, moisture and probably traces of the alkali used as electrolyte. The gas is mostly purified by passing it through a furnace containing an electrically heated catalyst, in order to combine the excess of oxygen with hydrogen to form water.

Owing to the increasing demand for hydrogen, a great number of inventors in all parts of the world have concentrated their attention on the design of a efficient electrolytic cell and a large patent literatu... already covers this subject. The majority of tl... suggested types, however, has not passed beyond th... drawing board or the experimental stage. Of thos... few types which have found their way into practica... use, most are limited by their special design to ... comparatively small specific output, too small fo... commercial use on a large scale. The reason for this limited success may depend upon the fact that only a few inventors have had the opportunity of actually running large electrolytic plants for a number of years, and therefore lack the practical experience and knowledge of the requirements essential for the design of an efficient and reliable electrolytic cell.

A type of cell which has proved to be highly efficient and economical is the Holmboe hydrogen generator, designed by C. F. Holmboe, D.Sc., the managing director of De Nordiske Fabriker, Denofa A/S, in Fredriksstad, Norway. The first units of these cells were started up in 1919, and have been in continuous operation since, day and night without stop. The cells have up to the present neither been opened for inspection nor has any part been repaired or renewed. They have been filled twice a day with distilled water, which is all the work required.

Fig. 1 illustrates the battery of Holmboe hydrogen generators, installed at the Denofa works at Fred-

ikksstad. The cells, which are of the 3000-ampere type, are totally enclosed.* In the cell-room, shown in Fig. 1, are 400 cells. On each shift only one man is required to look after the plant, his work consisting in the control-analysis of the gases, keeping the cells filled with distilled water, and looking after the stills for the production of distilled water.

The electrolytic efficiency of the Holmboe hydrogen generator is equal to about 7·3 cb. ft. of hydrogen per kw.-hr., measured at 20° C. and 760 mm. taken as an average over one year. The efficiency varies with the output between 7·1 and 7·6 cb. ft. hydrogen

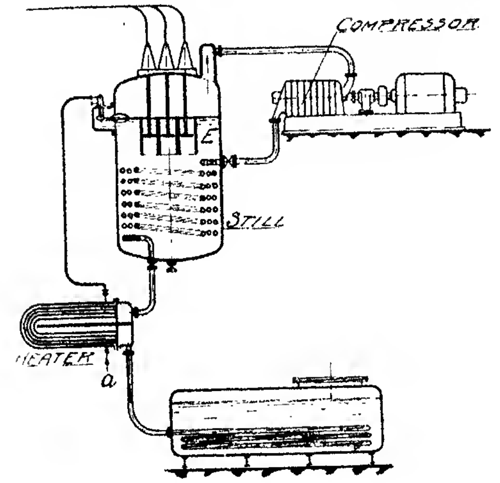

Fig. 2

per kw.-hr., and is remarkably constant, although the gas output from month to month can fluctuate 30 per cent. above and below the medium output. This fact is due to the electrothermal storage in the cells themselves, which is a special feature of the Holmboe hydrogen generators.

The hydrogen leaves the cells with a purity of 100 per cent., the traces of moisture being separated by a special device. The oxygen has an average purity of 99·75 per cent., and can be compressed direct into cylinders. A special purification of the two gases is therefore not necessary. The floor-space and building required for the Holmboe hydrogen generators are very moderate and the cost of the building with normal foundations only about 30-50 per cent. of the cost of the plant, depending upon the size. The total power of the power station attached to the plant is 7500 kw. d.c.

Owing to the high efficiency and the simple and durable design of the Holmboe hydrogen generators, the total production cost is very moderate. The plant illustrated in Fig. 1 produces 1000 cb. ft. of hydrogen in the gas-holders of the works at a total cost of 1s. 9d., including cost of power, distilled water, labour, sundry expenses, interest on capital invested in the plant and maintenance.

It is very important that the cells are supplied with pure distilled water. A new method of producing distilled water, particularly in cases where cheap power is available, is illustrated in the drawing, Fig. 2. The still is fitted with electrodes E (in this type 3 electrodes for 3-phase alternating current) and a system of coils. When the current passes through the electrodes the water in the still begins to evaporate. The steam so produced passes through a pipe connected to a motor-driven centrifugal-compressor in which the steam pressure is increased. This steam, at a pressure higher than atmospheric, flows through the coil-system in the still and in condensing gives off most of its heat to the water in the still. From the coil in the still the condensate and what may be left of the steam pass through a heater and thus into the large storage tank for distilled water. The electrodes carry in actual operation only a little more than the current equal to the heat required for raising the temperature of the feed-water to about 110° C. plus the heat lost by radiation. The fresh water enters the heater at "a," is pre-heated and passes to the float-valve which keeps the water-level constant in the still. This method of producing distilled water is very simple, efficient and highly economical where water power at moderate cost is at hand.

* So that escape of alkaline particles from the electrolyte (which has proved so unpleasant a feature of open cells) is quite impossible, and fitted with a special equalising device for the gas pressures.

PULVERISED FUEL FOR STEAM GENERATION

(From a Correspondent)

The North Metropolitan Electric Power Supply Co. have now placed with Messrs. The Underfeed Stoker Co., Ltd., for their Willesden electricity station, the first order in Great Britain for a modern "Lopulco" pulverised fuel equipment, to be applied to one "Clayton" water tube boiler of a normal duty of 60,000 lb. water evaporated per hour, to be running in October. This fact is significant, as it means that the struggle between pulverised fuel and mechanical stoking (of which the two general types are the improved travelling grate and the multiple retort) for supremacy in the water tube boiler world has spread in earnest to Great Britain, following on the enormous developments in the United States during the past three years, and the very recent orders in France for the Vitry and the Gennevilliers stations.

The matter is particularly interesting to the chemical engineer, because there seems to be every indication that the many difficult problems of burning fuel in a pulverised condition under water tube boilers have been solved, and one may expect sooner or later equal progress not only in metallurgical and general furnace work, but also for cylindrical boilers on land and sea, as well as locomotives.

The installation at Willesden is to consist of the latest type of "Clayton" bent tube type water-tube boilers, as suitable for the purest feed water, with a heating surface of 7200 sq. ft., working at 200 lb. pressure, and 650° F. superheat, the temperature of the inlet feed-water being 150° F, the rating with

ordinary mechanical stoking being 50,000 lb. of steam per hour actual.

The "Lopulco" pulverised fuel equipment will consist of one of the newest vertical gravity coal driers, utilising only the hot exit flue gases in the chimney base, mixed with air to give a temperature of about 215° F., working in conjunction with a "Raymond" pulveriser of the 6-roll, low-sided type, the combined set having a duty of 6 tons of bituminous coal per hour, reducing the moisture from 10% to 4%. It is interesting to note that one of the latest developments in pulverised fuel fixing is that only the mechanical moisture is now found to be of importance, and excessive drying is no longer regarded as necessary. The fineness of the grinding is to be 90% through a 100 mesh, and 80–85% through a 200 mesh, being therefore somewhat finer than the usual 65% through 200 mesh. The coal as it enters the plant, before passing to the overhead bunkers above the vertical drier, will be crushed so as to pass wholly through a ¾ in. screen.

The pulverised coal is separated automatically in the pulveriser by means of a continuous enclosed air current, and conveyed to the overhead pulverised coal bunker, after passing through a cyclone separator to disentangle the fuel from the air. The apparatus includes two standard "Lopulco" variable speed 3-group feeders, supplying therefore in all 6 "Lopulco" burners in the top of the combustion chamber pointing downwards in the usual way. The combustion chamber is of the most modern design, with large volume, and hollow firebrick walls throughout, including the usual air inlet ports and regulating devices, and will be fitted with the patent "Detrick" suspended firebrick arch, in addition of course to the essential "Lopulco" water screen, consisting of 4-in. water-cooled steel tubes in the bottom of the chamber in circuit with the boiler so as to prevent the melting of the ash (slagging). Further, also the plant includes two "Usco" air heaters which will preheat the air for combustion to 300° F. before passing into the hollow walls, reducing the final flue gas temperature to 359° F. The air then passes into the combustion chamber at 600–800° F., thus increasing the efficiency of the combustion and cooling the brickwork at the same time.

The normal duty coal consumption will be 8840 lb. per hour of coal, which will be of the ordinary semi-bituminous quality, with a lower calorific value of 10,000 B.Th.U. as received. This will be equivalent to a normal evaporation of 60,000 lb. water per hour actual, together with a long overload of 72,000 lb., and in addition the guarantee includes a maximum peak load duty for two hours' operation of 80,000 lb. per hour, an interesting point in view of the controversy as to the alleged high cost of pulverised fuel equipment and also because of the fluctuation in the demand for steam in the chemical industry.

The efficiency guarantee is amazing, being no less than 80 per cent., based on the nett calorific value of the fuel, and is higher than the latest American installations, corresponding to only about 20 per cent. excess air above the theoretical and 17 per cent. carbon dioxide, the average industrial plant being 75–120 per cent. excess air, 6–8 per cent. carbon dioxide, and less than 60 per cent. efficiency.

FORTHCOMING EVENTS

May 5. SOCIETY OF CHEMICAL INDUSTRY, *London Section*. Annual meeting at the Chemical Society, Burlington House, W. 1, at 8 p.m. "Bauxite as a Refining Agent." Part 1, General, by A. G. Dunstan, D.Sc., F. B. Thole, D.Sc., and F. G. P. Remfry, D.Sc. Part 2, "Application in the Refinery," by A. M. O'Brien.

May 5. ROYAL SOCIETY OF ARTS, John Street, Adelphi, at 8 p.m. "Photography in Industry, Science, and Medicine," by T. Thorne Baker.

May 5. UNIVERSITY OF LONDON, University College, Gower Street, W.C. 1, at 5.30 p.m. "Positive and Negative Valences," Prof. W. A. Noyes.

May 5. INSTITUTION OF THE RUBBER INDUSTRY, *London Section*, Engineers' Club, Coventry Street, London, W., at 8 p.m. "The Rubber Industry —A Plea for Closer Working," by J. Fairbairn

May 6. ROYAL COLLEGE OF SCIENCE CHEMICAL SOCIETY, Royal College of Science, South Kensington, S.W. 7, at 5 p.m. "Fuel Cells or the Direct Conversion of Fuel Energy into Electrical Energy," Prof. A. J. Allmand, D.Sc.

May 6. SOCIETY OF CHEMICAL INDUSTRY, *Bristol Section*, the University Chemical Department, Bristol, at 7.30 p.m. "The Somerset Oil Shale Fields," by Dr. W. F. Leslie.

May 6. ROYAL PHOTOGRAPHIC SOCIETY, 35, Russell Square, W.C. 1, at 7. Fourth Harter and Driffield Memorial Lecture, "Tone Reproduction in Photography." Dr. C. E. K. Mees.

May 7. SOCIETY OF PUBLIC ANALYSTS, Chemical Society's Rooms, Burlington House, Piccadilly, W. 1, at 8 p.m. (1) Determination of Sugar in Urine by Means of Fehling's Solution with Methylene Blue as Internal Indicator," by J. H. Lane and L. Eynon. (2) "Simple Forms of Hydrogen Electrode," J. J. Considene. (3) "Note on the Recognition of Hydrogenated Oils," by K. A. Williams and E. R. Bolton. (4) "Estimation of Copper and Tin, and Copper-Tin Alloys," by A. T. Etheridge. (5) "Notes on the Analysis of Milk Powders and Condensed Milks," by D. W. Steuart. Informal dinner will be held at 6.30 p.m. at the St. James's Restaurant 178, Piccadilly, W. 1.

May 8. INSTITUTION OF ELECTRICAL ENGINEERS, Savoy Place, Victoria Embankment, London, W.C. 2. at 6 p.m. Annual General Meeting.

May 8 and 9. IRON AND STEEL INSTITUTE, at the Institution of Civil Engineers, Great George Street, London, S.W. 1. Annual Meeting. Annual dinner at the Hotel Cecil, Strand, on May 8, at 7.30 p.m.

June 11 to 13. SOCIETY OF DYERS AND COLOURISTS. Annual dinner on June 11 at the Hotel Victoria Northumberland Avenue, London, S.W. 1. Conference on June 11 and 12 at the British Empire Exhibition, Wembley; on June 11 (3 p.m.) J. R. Hannay will give "An Historical Survey of Dyeing and Calico Printing," and on June 12 (11 a.m.) Prof. A. G. Green, F.R.S., will speak on "Modern Methods of Dyeing." River outing (cost 15s. per person) to Windsor on June 13. Application for tickets should be made to the Society of Dyers and Colourists, 30, Pearl Assurance Buildings, Bradford, before May 10.

SOCIETY OF CHEMICAL INDUSTRY

ANNUAL GENERAL MEETING, 1924

PATRON: H.M. THE KING

In accordance with the provisions of by-law 68 notice is hereby given that the Annual General Meeting of the Society of Chemical Industry will be held in the Arts Theatre, The University, Liverpool, on Wednesday, July 9, 1924, at 11 a.m.

A preliminary programme appears on this page.

In accordance with the provisions of by-law 23 intimation is hereby given that the following members of Council retire from their respective offices at the forthcoming Annual General Meeting: Dr. E. F. Armstrong, F.R.S., *President*; Mr. Julian L. Baker, Mr. C. S. Garland, Sir Max Muspratt, Bart., and Sir Wm. J. Pope, K.B.E., *Vice-Presidents*; Mr. John Allan, Prof. J. W. Hinchley, Dr. J. H. Paterson, and Mr. W. J. U. Woolcock, C.B.E., *Ordinary Members*.

Mr. W. J. U. Woolcock, C.B.E., has been nominated for election to the office of President under by-law 19; Dr. E. F. Armstrong, F.R.S., Prof. J. W. Hinchley, Prof. J. C. Philip, F.R.S., and Sir Richard Threlfall, K.B.E., F.R.S., have been nominated Vice-Presidents under by-law 20.

Mr. E. V. Evans has been re-elected Hon. Treasurer, and Sir Wm. J. Pope, K.B.E., has been re-elected Hon. Foreign Secretary.

Members are requested to nominate, on or before May 9 next, fit and proper persons to fill the four vacancies among the Ordinary Members of Council. Forms for this purpose can be obtained from the General Secretary of the Society.

By-law 22.—An Ordinary Member of Council shall be nominated by five or more members upon Form B in the Schedule, a copy of which form shall be furnished by the General Secretary upon the written or verbal request of any member, but a member shall not be eligible to sign more than one such nomination form, and the member nominated shall sign the declaration set forth on the form.

A nomination shall be declared invalid by the Council if:—

(*a*) The member thereon nominated is disqualified for election, or ineligible to be elected, as provided by the by-laws.

(*b*) The nomination is not made on the authorised printed form, or substantially not in the manner directed thereon.

(*c*) The nomination form is signed by less than five members not disqualified or not ineligible to nominate as provided by the by-laws.

(*d*) The nomination form is not received before or upon the day appointed therefor.

(*e*) The member nominated has not signed the declaration printed upon the form.

A member whose nomination aforesaid is declared to be invalid shall receive notice thereof from the General Secretary, and shall not be submitted for election.

J. P. LONGSTAFF,
General Secretary

The following is a Preliminary Programme of the meetings to be held in Liverpool on July 9-12 inclusive.

WEDNESDAY, JULY 9.—*Morning*: Council Meeting. Annual General Meeting in the Arts Theatre, the University. Presidential Address by E. Frankland Armstrong, D.Sc., F.R.S.; *Afternoon*: Business Session in the University. Visit to White Star Liner "Cedric," and tea on board by invitation of the White Star Line. *Evening*: Reception and Dance at the Town Hall by invitation of the Right Hon. The Lord Mayor of Liverpool (Arnold Rushton, Esq.).

THURSDAY, JULY 10.—*Morning*: Messel Memorial Lecture by the Right Hon. Viscount Leverhulme, in the Arts Theatre, the University, and presentation to the Lecturer of the Society's Messel Medal for 1924. Visit to the works of Messrs. Joseph Crosfield & Sons, Ltd., Warrington. Luncheon by invitation of the Directors. *Afternoon*: Inspection of the Works. *Evening*: Annual Dinner of the Society at the Midland Adelphi Hotel.

FRIDAY, JULY 11. *Morning*: Business Session in the University. Luncheon at the Midland Adelphi Hotel, by invitation of the Chairman and Directors of the United Alkali Co., Ltd. Visit to a Works of the United Alkali Co., Ltd. *Evening*: Dinner at Lady Lever Art Gallery by invitation of the Chairman and Directors of Messrs. Lever Brothers, Ltd.

SATURDAY, JULY 12.—Visit to Lake Vyrnwy. Inspection of Liverpool Corporation Water Works.

A detailed programme will be sent later to every member of the Society.

Members are asked meantime to note that the railway companies in Great Britain (except the Metropolitan and London Electric Railway Companies) have agreed to issue tickets at the ordinary single fare and one-third for the double journey to passengers travelling to attend the meeting. The tickets will be available from July 8 to 14.

LIST OF MEMBERS ELECTED,

11th April, 1924

Baborovsky, Jiri, University of Technology, Falkensteinerova 7, Brno, Czechoslovakia. Professor of Physical Chemistry.

Cross, Reginald B., Daisybank, Maxwell Road, East Kilbride, Scotland.

Desbarats, H. Jean, Cascade Inn, Shawinigan Falls, P.Q., Canada. Works Foreman.

Fujioka, Chuji, Imperial Hygienic Laboratory, Igumi-cho, Kanda-ku, Tokyo, Japan. Research Chemist.

Furlong, John R., 75, Swinderby Road, Wembley, Middlesex. Research Chemist.

Herapath, Cyril A., "Newgrove," 142, Church Road, Upper Norwood, London, S.E. 19. Chemist.

Hickinbottom, Wilfred J., 46 Frederick Road, Stechford, Birmingham. University Lecturer.

Holland, W. W., Standard Oil Co. (Indiana), Wood River, Ill., U.S.A. Oil Refiner.

Jones, Ronald H., 28, Capel Road, Clydach, Swansea. Analytical Chemist.

Kuchiki, Yoshio, c/o Japanese Embassy, 37, Portman Square, London, W. 1. Chemical Engineer.

Lewkowitsch, Miss P. R. Elsa, 71, Priory Road, W. Hampstead, London, N.W. 6. Student.

Oka, Shunpei, c/o Dept. of Applied Chemistry, Faculty of Engineering, Tokyo Imperial University, Tokyo, Japan. Research Chemist.

Rogers, L. Joslyn, Mining Building, University of Toronto, Ont., Canada. Professor of Chemistry.

Sands, James E., Robinson Road, Mapperley, Nottingham. Laboratory Furnisher.

Short, William A., United Alkali Co., Ltd., Cunard Building, Liverpool. Managing Director.

Westwood, John B., Abbey Brewery, Edinburgh. Chemist.

NOTTINGHAM SECTION

At the meeting on March 26, Dr. E. B. R. Prideaux in presenting the annual report, said the session now drawing to a close had been characterised by a testing and adaptation of the new policies which had been initiated in preceding sessions. Although the leading members of the council had not been free from anxiety on the financial side, it had been decided to continue boldly the weekly publication of *Chemistry and Industry* as a high-class journal, in the forefront of science and at the same time popular in the best sense. Most members will agree that it is unique in these respects even if they do not give their unqualified approval in others. A pleasing feature is the liberal space now allotted to sectional meetings and discussions, which form part of the Society's activities. The co-operation with the Chemical Society had continued in the direction of granting mutual privileges in respect of subscriptions. The process of unifying the abstracts of the two societies was also rapidly approaching completion. The facility afforded for reading at our sectional meetings papers intended for publication in the Chemical Society had not been as largely taken advantage of as was originally intended, but it was hoped that members would bear it in mind as occasion arises.

The lamentable loss of our chairman, fresh as it was in our minds, called for mention, since he was secretary of the Section for so many years. Only those who now continue that responsibility would realise how much his experience was missed. He had already last autumn made preliminary arrangements to secure the lecture from Prof. A. R. Ling on the history of fermentation.

In passing it was perhaps not out of place to record our congratulations to Mr. S. J. Pentecost, on his accession to the presidency of the Society of Dyers and Colourists. There had been seven meetings in the session, one of which was held jointly with the Society of Dyers and Colourists. On this occasion Mr. K. H. Saunders read a paper by himself and Prof. A. G. Green, F.R.S., on the "ionamine" dyestuffs. At the opening meeting the late chairman touched on some important aspects of chemistry in its application to the discovery of accessory food factors and the supply of fertilisers in agriculture. The paper was followed by an interesting note by Dr. Firth and Mr. J. Higson on the products of the action of sodium hyposulphite on silver nitrate. The next meeting, contributed by members of the College, described researches in bacteriology, organic compounds, and regulators of acidity. The Section was indebted to the Stanton Iron Works for two papers. Mr. Woodhouse described the use of the metallurgical microscope and photomicrography and Mr. G. J. Ward gave an account of the manufacture of concrete pipes. Finally, from the laboratory of Mr. S. R. Trotman, there were communicated the results of researches by himself and Mr. R. W. Sutton on the analysis of gelatin, examination by chemical and microscopical methods of foodstuffs, textiles, etc. The paper on the weathering of cotton and wool was the latest of a long series through which Mr. Trotman had advanced step by step in the elucidation of textile problems.

Early in 1924 a sectional list of members with rules, etc., was compiled in response to a demand which had become somewhat pressing, since the last edition was in 1917-1918. The membership of the Section was now about 150. The proportion, however, that attended the meetings could not be considered satisfactory, even when allowing for the dispersion of members in the East Midlands area, and for those who resided abroad or in other areas. The associate membership had been maintained by the addition of new members, many of whom were not only keen in attending the meetings, but also took part in the discussions.

There was probably no meeting, whatever its nature, from which even the oldest and most experienced members did not carry away something of value. Technical men might be assisted to follow recent progress in general chemical knowledge; academic men had an opportunity of being impressed by advances in applied chemistry shortly after these are made. The younger men, whose academic knowledge should be more up-to-date, needed to keep in constant touch with progress in pure and applied chemistry, since upon them would devolve the responsibility for the chemical industry. Technical chemists especially might use these meetings to broaden the basis of their knowledge. How much more conclusive our discussions would become if a group were to "get up" the subject of the paper, with the intention of informing the meeting and settling doubtful points.

Chemical industries must always be progressive in their nature, and all industries had become with the advance of science more or less chemical industries. The only real hope of maintaining these in the face of ever increasing international competition was for the technical man, more especially the chemist, to make himself susceptible to knowledge from whatever quarter it might blow and for the manufacturer to realise his need for educated and alert men, to treat them generously and to increase their numbers in proportion as he discovers their beneficial effect on the quality of products and economy of production.

SOCIETY OF GLASS TECHNOLOGY

The seventh Annual General Meeting was held in Sheffield on April 16, the president, Prof. W. E. S. Turner, D.Sc., in the chair. Col. S. C. Halse, was elected President in succession to Prof. W. E. S. Turner. The other vacancies were filled as follows: Vice-presidents, F. G. Clark, R. L. Frink; Members of Council, H. A. Bateson, W. R. Dale, J. Moncrieff, W. J. Rees, B.Sc. Tech., J. H. Steele, J.P., and H. Webb; Hon. Treasurer, J. Connolly; American Treasurer Wm. M. Clark, Ph.B.; Hon. Secretary, S. English, M.Sc.; Auditors, Ed. Meigh, M.Sc., and Dennis Wood, F.S.A.A. The Annual Report and Accounts showed that 1923 was a successful year. The foreign membership continued to increase, numbering 190 (including 109 resident in the United States) out of 615 at the end of 1923. Altogether the society was connected by membership with no fewer than seventeen countries. Prof. H. Le Chatelier, Paris, was elected honorary member of the society.

A paper entitled "The Physical Properties of Some Alloys Resistant to Heat and Corrosion" was read by J. H. G. Monypenny, F.Inst.P., who dealt with problems which might occur in machinery pertaining to the glass industry, and said there were also certain general engineering uses for material having these special properties, such as the application of the material to various fittings for steam service and hydraulic work. Dealing first with stainless steel, he outlined the range of properties obtainable, dwelling also on the mechanical and heat-resisting properties. Passing on to alloys developed for special properties, particulars were given of stainless material in which resistance to mineral acids had been greatly increased, and the tendency for galvanic action in contact with bronze and other copper alloys entirely removed. A short description of some special alloys which had been developed for resisting scaling was given. A sample exposed in a brick kiln for a fortnight, the temperature reaching 1200° C., revealed a total change in weight of only 0·04 per cent. The glass industry required alloys suitable for a number of special purposes, in some cases for resisting general corrosion, and in others for resisting the effects of high temperatures. Probably no single alloy would be suitable for all purposes, though for any of those purposes some type of stainless steel would be found useful. For developing any one special property in an exceptional degree, it was generally found necessary to sacrifice other properties to some extent, so that it was advisable for the maker and the user to collaborate.

Mr. W. R. Barclay, A.M.I.E.E., followed with a paper entitled "Some Properties and Possible Industrial Uses of Alloys containing Nickel," devoted to two alloys, the simple nickel-copper series and the nickel-chromium series, with no other metals added. Referring to the nickel-copper alloys he emphasised their remarkable ductility, combined with considerable toughness and strength, and very considerable resistance to corrosion. A retention of strength at temperatures higher than those at which ordinary non-ferrous metals broke down was particularly evident in the nickel-copper alloys containing high nickel. As an illustration of the enormous ductility, he quoted a recent example of material manufactured, in which it has been possible to cold-work a 2 in. bar right down to 0·2 in. without annealing. The two nickel-chromium alloys hitherto developed were the 85 per cent. nickel, 15 per cent. chromium, and the 80 per cent. nickel, 20 per cent. chromium. They were remarkable materials, bridging the great gulf that had hitherto existed between ferrous and non-ferrous materials, and combining in a high degree the best properties of both. These were the alloys which had made modern developments of electric heating possible. A very important application was their use in annealing furnaces.

During the morning an exhibition of special steel and non-ferrous alloys, and of tools and plant made from them, was held in the Department of Glass Technology of the University of Sheffield. The following firms exhibited: Brown Bayley's Steel Works, Ltd., Sheffield; Cronite Foundry Co., Ltd., Tottenham, London; T. Firth and Sons, Ltd., Sheffield; Foster Instrument Co., Ltd., Letchworth; H. Wiggin and Co., Ltd., Birmingham; T. G. Wolstenholme and Sons, Sheffield.

SOCIÉTÉ DE CHIMIE INDUSTRIELLE

The fourth Congress of this Society will be held in Bordeaux from June 15 to 21, and local committees are already at work. The Congress will be divided into six groups, viz.: (1) Works and laboratory, (2) Fuels, (3) Metallurgical and mineral industries, (4) Organic industries, (5) Agriculture and agricultural industries, and (6) Economic organisation. The main programme of the Congress will be as follows: *Sunday, June* 15, arrival at Bordeaux, and visit to the Fair. In the evening there will be a reception by the Organising Committee in the Grand Theatre. *Monday, June* 16, the Congress will be formally opened, and will be followed by conferences and meetings of the presidents and secretaries of the groups. In the evening there will be meetings of the sections of the conference and a reception at the Bordeaux Town Hall. On the morning of *Tuesday, June* 17, there will be visits to dockyards and factories, followed by sectional meetings. Further visits will be paid on the morning of *Wednesday, June* 18, and in the evening there will be sectional committee meetings followed by the formal meeting of closure, concluding with a banquet. On *Thursday, June* 19, there will be an excursion in the Graves and Sauterne districts, including the tasting of the principal "crus," and concluding with a banquet. Numerous excursions of great interest will also be arranged for June 20.

As in former years, numerous foreign societies have been invited, and we are asked to state that the Société de Chimie Industrielle hopes to receive at Bordeaux a large delegation from Great Britain, and in particular from the Society of Chemical Industry.

CORRESPONDENCE

LEGISLATION IN RELATION TO CHEMICAL INDUSTRY

Sir,—In your last issue you comment on the learned Referee's award in the recent complaint against the inclusion of "Rongalite" in the list of scheduled chemicals under the Safeguarding of Industries Act, and the associations of this award with the articles that appeared in your columns about a year ago upon the definition of the chemical terms used in the Act. The fact that these articles figured so prominently in these recent proceedings not only furnishes the occasion, but also, I venture to think, constitutes a complete justification, for the consideration in your columns of the several issues raised thereby, affecting, as they do, legislation in its relation to chemical industry, and the true position of the scientific man who contributes towards their solution by giving evidence in the public courts.

At the Rongalite hearing I only had the opportunity of giving evidence as a buyer of chemicals; I would claim the hospitality of your columns on a broader plea, for not only am I an original member of our Society, but I am one of the few now left who saw its constitution hammered out at the earlier meetings, when it barely escaped entering upon its career under the narrower title of the Society of Chemical Engineers.

The matter presents itself in three aspects:—

I. The relation of the chemist to the Act in its drafting, passage through Parliament, and subsequent application in practice.

II. The position of the chemist as witness during the hearing of the cases under the Act, particularly as regards the policy of acting as an advocate for a particular issue.

III. The consideration as to how the chemist comes out of the ordeal, and how his status in the eyes of the public as a professional man is influenced thereby, and what lessons may be learned therefrom.

I. Definitions under the Act—The essential point of interest in the Act to the chemist engaged in industry is the schedule accompanying the first part of the Act and the resultant list prepared by the Board of Trade of 3000 or so chemicals listed as fine chemicals, synthetic organic chemicals, analytical chemicals or fermentation products. Seldom has a clause in an Act of Parliament been subjected to such destructive criticism, and this reached its climax in the onslaught of Sir William Pope on the Carbide decision in his letter to the *Times* of December 8, 1922 reproduced in your January issue of 1923, and elaborated in the three articles already referred to, published by you about the same time.

In your current leading article you comment on the desirability of a Court of Chemists that should frame definitions of the terms used in the Act. This advice is wise, but somewhat belated, and the Court you suggest is not only without representation of that body of chemists which was the only one that at the inception of the Act recognised the necessity of defining its terms before they were put into operation, but which also from the industrial character of its membership is the best fitted to advise upon their formulation. The British Association of Chemists took action before the first hearing of a case in the Referee's court, and by ventilation of the matter in the *Times* and other newspapers, and by negotiations with kindred societies, strove to get chemists to put forward authoritative definitions which would guide the Referee in his decisions, and so would consequently have reduced to a minimum the acrimonious and confusing proceedings in the Referee's court that, in the opinion of Sir William Pope, constituted a "ridiculous farce," a judgment too severe, though not entirely unmerited. Had that been true, the blame would not have lain with the Referee, whose conduct of the cases has been irreproachable, but with the chemists themselves, who had burked the issue, for, apart from the B.A.C., the Manchester section of our Society was, so far as I remember, the only body of chemists who made any effort to solve it, and even they gave up the attempt.

The terms used in the Act, "fine chemical," "synthetic organic chemical," etc., have no fixed and invariable significance to the chemist or technician, and the one that has been most discussed, and to which I shall confine myself, viz., that of "synthetic organic chemical," conveys to the professor in his university a very different meaning to that which it does to the technical chemist in his works. The first point that emerges therefore in considering the proper definition of the terms is to decide to whom the Act is addressed, and who as a consequence will be the proper authority to give its terms their interpretation. The preamble of the B.A.C. letter to the *Times* above referred to states accurately, it appears to me, both the conditions under which the terms should be interpreted and the type of person to whom they are addressed. It states: "The governing terms employed in this Act are not interpretable in purely scientific terms. The contents and avowed object of the Act must, and accepted commercial usage should, be taken into consideration. What is immediately necessary is to secure the expression of a considered opinion by chemists with commercial experience reconciling the views of those producing and those consuming 'chemicals' as an authoritative guide to the administration of the Act." What, then, should have been the attitude of the professional man to the Act in its early stage of incubation? The profession should have been so organised that it would have had spokesmen in the House of Commons who could have pointed out the futility of using terms upon which those competent to judge would inevitably have been in disagreement if the forms used were maintained, and an effort should have been made to have such clear-cut definitions adjusted as would have gained common acceptance, and so served as a guide to the Referee and simplified the task of this much maligned but extraordinarily patient public servant.

II. The chemist in the witness-box.—I sat through the hearing of the Oxalic case, the Formaldehyde case, and the Rongalite case, but my remarks under the present section will be confined to the last named. If Sir William Pope's statement in reference to the earlier cases (and in particular the Calcium Carbide

case), that the proceedings were "an orgy of misinterpretation and misrepresentation" is approximately accurate as describing the general method of trial and the part played by the chemist who contributed to that method being carried out, then I would say that that "orgy," if such be the proper expression, repeated itself in the last trial at which Sir William was himself present, and it is to the evidence that was given in that trial that I propose to apply myself. It is unfortunate that this cannot be done shortly, but its importance must be the justification of its length.

The issue of the trial pivoted on the articles by Sir William Pope already referred to, and his extension (I should prefer the term abandonment) of the definition given by him in those articles of the term "synthetic organic chemical." Sir William's third article in this *Journal* concentrated on the definition of an organic synthesis as residing in the linking up with one another of carbon atoms which previously were not combined or were not combined together. This definition was necessary to class calcium carbide as a synthetic organic chemical. Sir William's revised definition, as used in the Rongalite case, and accepted without question by the Referee, was that the "word synthesis means the artificial formation of a particular group or unit of constitution which was not previously present." Some such definition as this is necessary if Rongalite is to be classed as a synthetic organic chemical, seeing that it contains only one carbon atom, and therefore the linkage definition fails when applied to it. How such a definition becomes at once a trap was evident from the fact that Sir William under it excluded mono-chlor-benzene from the synthetic class on the ground that "the replacement of the Hydrogen atom by the Chlorine atom was such a simple operation," and it did not help the Referee out of his difficulties to have Prof. Collie immediately afterwards differing from Sir William as to the synthetic character of this mono-chlor body.

The matter to which I wish to address myself is whether the original definition given by Sir William in his article in your paper, or the new *ad hoc* definition given by him in this particular case, is the true definition, and the one that would gain assent from the general body of chemists to whom this Act is addressed.

The point I hope to establish is that Sir Wm. Pope, in the admirably conceived and fully documented article, pages 169-170 of the 1923 issue of this *Journal*, gives a definition based on an exhaustive review of the minds of leading organic chemists, whose opinions are entitled to acceptance; that their definitions are clearly stated, incapable of misinterpretation, and cumulatively decisive, and that they are not accompanied in the works in which these authors give them by any subtractions or enlargements that render them other than what they profess to be. As against this, Sir William stated that the word "synthetic" has changed in meaning with the development of chemical science, and he goes on to say (I quote him verbatim): "I can illustrate that by taking one of our most modern works on organic substances, Posner, from which an extract has already been read, and then simply reading on find lines in continuation of the quotation; Posner goes on to say: 'in the present book, however, the idea of synthesis shall be used in the widest possible sense, namely, for the whole collection of artificial methods for preparing chemical compounds in opposition or contrast to the simple isolation of them from the natural products.'" Sir William then continued, repeating his new definition: "This is our modern idea of chemical synthesis; it means the creation of a new unit of constitution which was not previously present." The intelligent reader will hardly admit that Posner does really mean this, but I shall return to that point later.

It will, I think, be admitted that if Sir William Pope, in quoting this presumed extension of Posner's definition, had intended to convey that the author really meant in any sense to jettison his clearly worded definition in favour of one of much wider scope, and if Sir William thereby sought to establish a justification of his own abandonment of the arguments used by him on the Carbide case, such presentation of the fact would justify the Referee in concluding that this was only one example which would equally apply to all the other definitions quoted in that article, and that each of the other authors had similarly widened his views in the pages of the works that were cited. Had this not been the case, it would have been proper for Sir William to have guarded the Referee from attaching such a general significance to the particular example quoted by him.

I think I shall be able to establish that not only did none of the other authorities quoted modify their definitions in any particulars whatever, but also that Posner in the words quoted has no intention of departing from the definition that he specifically and categorically puts forward. If I succeed in establishing this, I think I may claim that Sir William's "Rongalite" definition of organic synthesis is peculiar to himself and does not carry the seal of the recognised authorities whom he quotes in his article.

This is best done by taking these authorities in the order of their date, viz.:—Lieben (1868), Elbs (1889), Posner (1903), and Richter (1909). The other authorities quoted, Dalton, Berthelot, Meldola, are less relevant, and I accept Sir William Pope's view as indicated in his article, that they merely form links in the true line of descent of the idea of synthesis outlined by him in the article.

All these authorities agree that the formation of a carbon compound from its elements is true synthesis. This is outside debate, and it is taken as admitted in all the references that follow. The disputable ground is as to what reactions following on, or outside the range of, this first step, constitute a true synthesis.

Lieben, as quoted by Sir William Pope, is very specific. In Sir William's words, Lieben explained, in the "Annalen" of 1868, "very lucidly his reasons for restricting the term synthesis to those operations in which carbon atoms become actually joined together." So far from admitting that an organic body containing a single carbon atom can be syn-

thetic (save, of course, when the product of an elementary synthesis), Lieben refuses this designation to organic compounds formed by the combination of carbon containing groups when such carbon groups are joined together in the resultant compound by a non-carbon element (as, for example, oxygen), and he restricts the term to compounds formed by the direct linking of carbon atoms to one another. His statement of this position is elaborate and complete, and he fortifies it by specific examples. A special value attaches to the definition of synthesis given by Lieben in this paper, as it arises out of and is integral to the research work which it is the main purpose of the paper to set forth.

Elbs, following substantially on the lines of Lieben, is in a very special way decisive and conclusive. His whole statement of his view is particularly illuminating. His text might be taken as the best guide to an official definition of what an organic synthesis really is. He first takes the precaution of giving his definition in italics, and he then gives particular examples of bodies that ordinarily might be considered synthetic, but which are excluded by his definition; these examples being instances in which the number of carbon atoms in the resultant molecule in the one case remains unaltered, and in the other is increased, but in both cases the carbon linkages are in no way affected. The two cases quoted are the syntheses of urea from ammonium cyanate and ether from ethyl alcohol, and he points out that in the former case the carbon atom nucleus remains unaltered, and in the latter case that the two ethyl groups are separated by the oxygen linkage, and consequently the carbon nuclei remain unchanged.

No definition can be found that will be water-tight, and here Elbs boldly takes his courage in his hands and says in substance: This is my definition; any compounds that might by some be considered to be synthetic organic bodies are not such, for they do not come within my definition. Our present-day chemist will also have to take up this attitude if he is to elaborate a definition that will be valid and workable as a guide to the legal profession, who are likely to usurp his function if he does not bestir himself.

Richter does not put his definition so clearly as his predecessors. In fact the Referee rather boggled at it, but on careful reading there is no element of doubt as to his meaning. He says: "By the synthesis of *a carbon compound* is understood *its* building up from . . . such *carbon compounds* as could be produced from the elements." (The italics are mine.) This sentence clearly indicates the building up of a singular carbon body from a plurality of carbon compounds, that is an increase in the carbon atom contents of the body produced; and he further states on page 75 (1919 edition), quoting Lieben as an authority: "These reactions in which carbon atoms not before combined with one another become united claim particular importance in the synthesis of organic compounds," and he goes on to say: "such reactions are *the synthetic methods of organic chemistry* in the more restricted sense; in the future we shall designate them *nucleus-syntheses*." (The italics are his.) He describes no syntheses except such nucleus-syntheses and the syntheses from the elements themselves, so that these two classes constitute the totality of his synthetic methods. There is nothing to indicate (as presumed by some apparently to be the case) that the words, "more restricted sense," have any other meaning than to make this discrimination between the two classes named. I am sensible of, and admit the fact, that this second definition of Richter's does not run quite on all fours with the earlier one, for there may be a direct linkage of carbon atoms and consequently a true synthesis without addition to the number of carbon atoms in the molecule, but I have already said that Richter's definitions have not the clarity of those given by his predecessors.

None of the authors above mentioned have in the context modified by extension or subtraction the rigidity of the definitions they have put forward. In the case of Posner alone is this presumed to be the case, and I shall now deal with Sir William's caveat respecting Posner's definition. The first thing to notice is that Posner follows Elbs almost word for word. Having some experience as to how authors write books, I have no doubt that Posner had Elbs' book before him and copied his definition with such minor alterations as authors make under such circumstances. Quite a proper thing to do, but it is prima facie evidence that what Elbs meant, Posner also means. As regards Posner, Sir William, in quoting to the Referee the continuation of Posner's paragraph (and using this as a justification of his own extension of the definitions given by him in discussing the carbide decision), states that he only quoted so much of the authorities as was requisite for the establishment of the particular case with which he was then concerned. The following verbatim quotations of passages between the Referee (R.) and Sir William (P.) on this point are very illuminating:

"(R.) You say the word synthetic, according to all classical writers, is entirely applicable to the manufacture of calcium carbide. This is the use of the term you have elaborated in the article, is it not?"

"(P.) No, this is only a small part of it."

"(R.) It would have been a very strong authority to have produced if Sir William had not been here. In fact it would probably have been conclusively in your (*addressing the complainants*) favour; but then he is here, and he says: 'I was not meaning it in that way, and was only going so far as was necessary.' He tells us quite frankly that it does not represent his whole view but we might assume that it did if he was not here.

"(P.) I think I have shown that pretty clearly because I have given here a part of a passage from Posner, and then there is a continuation of it. I left the rest out because it was not necessary for my purpose."

Now, had I not been in court and heard Sir William's explanation of his reasons for this omission I should have thought he left it out because it was entirely irrelevant to the immediate issue and in no way modified the general statement of the definition

specifically given. I think this will be admitted by any candid reader of the passage referred to. In substance it amounts to this—I paraphrase, and I submit fairly paraphrase, Posner's paragraphs to bring out their significance. Having given his definition, Posner wishes to make it clear to his readers that, as it is his purpose in this particular work to treat in a collective way of all the group reactions of organic chemistry, he may wish to include cases that are wider than his definition. He therefore says: "In the following pages I shall, *notwithstanding* my definition (im vorliegenden Buch *jedoch*), adopt a much wider scope, and I shall consider as synthetic reactions all the reactions of organic chemistry." That this is the true meaning of the passage quoted by Sir William is confirmed by a later passage in Posner's book, where he seems to go out of his way to warn his readers against any preconceived misinterpretation of the passage in question. On page 158, after treating of the Perkin synthesis and allied reactions, he adds (I quote the original so that there may be no possibility of mistranslation): "Die genannten Reaktionen stellen wichtige wahre Synthesen (Kohlenstoffverkettungen) dar." Thus Posner comes round full circle and reiterates and clinches the definition with which his volume opens. This sentence is the true conclusion to the continuation of the passage quoted to the Referee, and it would have been helpful to him if it had also been placed before him. I would with all respect submit to Sir William that in the true line of descent from Posner he accept the Tennysonian dictum and recognise that "it is not true that second thoughts are best, but first and third which are a riper first." It is too late to ask the Referee to follow suit in the present case, but it would be fit matter for his consideration if the definition of synthesis comes up again for discussion in his court.

I shall not concern myself with Prof. Collie's definition of synthesis, as it has little bearing on the present issue, being concerned with laboratory preparations only, and including within its substance the very term which it is seeking to define.

III. Lessons.- Arising out of the foregoing, I would ask the chemist to consider, on the one hand, how ambiguous is his position in his relations to the formulation of the laws of the country on matters of vital interest to him in his professional capacity, and, on the other, how invidious is his position when he comes to participate in the interpretation of these laws as a witness in the courts, and I would ask him how far he is in a position to answer the following relevant questions:—

1st. How is it that the profession of chemistry is so unorganised that, in a case such as that of the passing of the Safeguarding Act, there was no body of chemists to whom the Government could turn for a considered and authoritative opinion as a guide in the drafting of the Act, with the reasonable assurance that such opinion would carry with it the assent of most of the chemists of the country?

2nd. How far is it consistent with the status of the profession that the help that should be given to the Government in the chemical aspects of its work (and, in particular, as crystallised in legislation) can only be got in the heated atmosphere of the law courts, and in the form of *ex parte* statements liable to the charge of prejudice?

3rd. Where is the court of honour at which chemists can get advice from the accredited leaders of the profession as to their proper conduct under such circumstances, and which will legislate as well as advise with respect to the ethics of the witness-box?

4th. When is the chemist going to realise the humiliating character of this condition of things, and when is he going to put his house in order?

One explanation (and it is the one given to me six years ago by one of our leading professors when I was trying to interest him in the new movement to found a British Association of Chemists) is that chemists are too individualistic as a class to act in concert for their own or the common good. In the interval, however, there has been seething and movement in the inert chemical mass. The B.A.C. has continued its struggling existence and is beginning to make good; the Institute has transformed itself and become revivified and powerful; the Federal Council has added a new and valuable weapon in your *Journal*; Prof. Baly, at Liverpool, has set forces into motion which should bring professional men into more intimate relation with one another; and the time is ripe for achieving that unity without which the chemist will remain a cipher in his influence on the vital movements of the times. Solidarity in the chemical profession is as essential to success as it is to the commercialist and the artisan. It has become a truism since the experiences of the war that with the chemist lies the future not only of national safety but also of industrial progress. There is exaggeration in this, but if the chemist is to play the part that has been assigned to him, his force must become collective and unitary, and the inner purpose of this letter (arrived at by a somewhat roundabout line of argument) is to urge upon the chemist that if he values his profession it, like the ship, must find itself if its voyage is to be safe and prosperous.—I am, Sir, etc.,

Wm. E. Kay

CONFERENCE OF THE SOCIETY OF DYERS AND COLOURISTS AT WEMBLEY

Sir,—This Society has made arrangements for a Conference at the British Empire Exhibition, Wembley, as follows:—Wednesday, June 11, at 3 p.m., Mr. J. R. Hannay, F.I.C., will give an address on "An Historical Survey of Dyeing and Calico Printing"; and on Thursday, June 12, at 11 a.m., Prof. A. G. Green, F.R.S., will give an address on "Modern Methods of Dyeing."

I am requested to give a hearty invitation to all members of the Society of Chemical Industry to attend both these Lectures.

On application to the Offices of the Society given below, special tickets admitting your members to the Exhibition Grounds and to the Lectures will

be supplied at a charge of 1s. 6d. each person for each Lecture. The Conference Authorities at Wembley will not permit persons to enter the Conference Hall without these special tickets. I would point out that the charge for these is not more than the usual charge for admission into the Exhibition Grounds only. Non-members of the Society can also attend our Annual Dinner and River Outing, if application is made to these Offices—I am, Sir, etc., J. B. Atkinson
Secretary

30, Pearl Assurance Buildings, Market Street, Bradford

[Attention is drawn to the announcement of the Conference in question in "Fortheoming Events," p. 460.]

BUILDING FOR PEACE

Sir,—The comments which you make on my letter in your editorial of March 28 induce me to write you a few lines in order to make my point of view in the question under discussion quite clear.

You wonder whether I saw Chauny soon after the end of the war. I did not. However, it may have appeared it could not have distressed a true friend of humanity more than the sight of East Prussia in August, 1914. In that province, as apparently you may not know, flourishing villages and towns were destroyed, and all the horrors of war let loose at the command of the Russian Government which was, almost at the same time, assuring the German Government that it did not intend to make war against Germany! The rest of our enemies entered into an alliance with this same Russian Government, which did not even observe the customs of the majority of savage tribes in warfare. Hence these Allies approved of these acts. It is, therefore, not too much to say that Germany has been attacked by robbers. Nothing is known which can in the slightest degree shake this belief. On the other hand, documents have come to the knowledge of the whole world which confirm the fact that the Allies approved of Russia's action, and which prove Belgium's guilt in the preparation for the attack. The Allied Governments have good reasons for concealing their documents concerning the cause of the war.

German scientific circles are by no means satisfied with the present relations with their colleagues on the Allied side, and would welcome a return to normal intercourse. This, however, must not take place on a basis of untruth and hypocrisy, but by spreading the truth. Hence we are at pains to have truth recognised, and are not giving up hope that it will prevail. From this point of view your remarks inspire some hope. For in the same manner in which the Boer War was recognised, after some time, in England to be a "mistake" on the part of the British Government, one can perhaps hope for a recognition of "mistaken" policy on the part of the same Government in the World War.

Incidentally, you would perform a meritorious action if you would request your correspondent, Mr. Hickman, to give you the name of the alleged German who declared in his office that the English were a dying nation, and that the Germans intended to take their place. This alleged German might be induced to sell his brain to an anatomical museum, as it would be of intense interest to many anatomists, for it proves an altogether extraordinary culture such as can no longer be found in Germany.—I am, Sir, etc., Dr. P. Fritzsche

April 14, 1924

"FATS: NATURAL AND SYNTHETIC"

Sir,—It is difficult to understand whether your correspondent "Labor omnia vincit" designs in his letter in this week's number of *Chemistry and Industry* merely to enliven with a little humour the somewhat staid annals of applied chemistry, or whether he intends to offer a serious criticism of the volume "Fats: Natural and Synthetic" published in our joint authorship in January last.

Lest some of your readers should take the latter view we desire to make a few comments on the insinuation, which is the substance of the letter, that a passage in the book extending over less than forty lines is a précis of the interesting and important article on "Hydrogenation Flavour," by Mr. K. H. Vakil, appearing in your columns on August 17, 1923. In these forty lines of "précis" we find the following points which do not appear in the August article:—

1. If an oil is treated under the conditions of hydrogenation but with an inactive nickel catalyst no characteristic odour is developed.

2. The odour is as pronounced in samples of oil which have been reduced by one or two units of iodine value as in samples which have been completely hydrogenated.

3. The "New acids of Hydrogenation" ("Iso-acids") are not produced under the conditions of 1.

In the "précis" we state that in laboratory hardened oils the hydrogenation odour is distinct although the hydrogen is not circulated and on this point we are in disagreement with Mr. Vakil. On the other hand, Mr. Vakil's article contains the following useful and interesting points which find no mention in our "précis":

1. The hydrogenation odour can be successfully removed from the hydrogen by treating the gas with a 10 per cent. solution of ferrous sulphate in a centrifugal scrubber.

2. The oil may be permanently deodorised by treatment with a current of a gas such as nitrogen or carbon dioxide.

3. The hydrogenation odour may be due to certain decompositions in the oil.

Mr. Vakil's article appeared only six weeks before we went to press, so that it was not possible for us to incorporate the above statements in our text, but if we had done so we should certainly have given a reference to the source of our information as we have consistently endeavoured to do throughout the work.

There are, nevertheless, some resemblances between the two writings, but these are merely references

to publications of other investigators which are naturally bound to appear in any adequate discussion of hydrogenation odour.

For example, the statement appears in both writings that the hydrogenation odour is incompatible with many perfumes or flavourings, but the same statement may be found in an article by one of the writers (W. W. M.) in the *Chemical Age* of April 28 of last year.

We feel bound to say that we strongly resent the publication in a responsible journal of a vindictive and misleading letter from a correspondent who has neither the courage nor the courtesy to append his name for publication.—We are, Sir, yours, &c.,

WM. W. MYDDLETON
T. HEDLEY BARRY

Chemical Department,
Birkbeck College
London, E.C. 4

PERSONAL AND OTHER ITEMS

The trustees of the Ramsay Memorial Fellowships for Chemical Research will consider, at the end of June, applications for not more than two fellowships, of which one is limited to candidates educated in Glasgow.

Monsieur S. Winogradsky of the Agricultural Laboratory of the Pasteur Institute has been elected a foreign associate of the Académie des Sciences in place of the late Monsieur Vanderwaals.

After 37 years' service, Dr. W. Beumer has resigned his post as economic editor of *Stahl und Eisen*.

According to the *Mining Magazine* a nodule of native arsenic has been discovered during the sinking of a shaft at Tolgus. This discovery is of considerable interest as the occurrence of uncombined arsenic has hitherto not been definitely recorded for the British Isles and a British specimen does not appear to be included in any public collection.

At the annual meeting of the American Institute of Chemists the following officers were elected: President, M. L. Crossley; vice-president, L. van Dorn; treasurer, C. K. Simon; secretary, L. R. Seidell.

Kommerzienrat C. Hilgenberg, who died on April 10, had been largely concerned in the development of the German potash industry.

Ing. W. Brückner, a well-known expert on heating problems, has died in Vienna, aged 79. Karl Schmeisser, who had been the first director of the Geological Institute and director of the Mining Academy in Berlin, died in Breslau, aged 68.

Holger Schmidt, a well-known figure in the Swedish soda industry, has died, aged 58 years.

Dr. Grunwaldt, a consulting chemist, who died recently, was the author of a work on the chemical technology of raw materials for enamels.

The death of K. T. Somlo deprives Austria of a technologist who had made many improvements in malting and distilling, particularly the development of the amylo process.

REVIEW

MECHANICAL STOKING. By DAVID BROWNLIE, B.Sc. Pp. x+234. London: Sir Isaac Pitman and Sons. 1923. Price 5s. net.

One of the outstanding features of the whole problem of the economic utilisation of fuel is that, whilst all are agreed that effective action must be taken and taken quickly, there rarely seems in practice to be any advance beyond the stage of suggestion and recommendation. Whereas every fuel consumer is prepared to listen to advice, only in rare instances is it possible to bring him to the point of carrying the suggestions put before him into practice, but the by no means inconsiderable bulk of recent literature bearing on the subject must surely tell in the end, and even now there are signs that the voices of the propagandists are not altogether crying in vain. The subject of steam-raising and boiler-house management is but one phase of the whole problem, but he who employs steam is, perhaps, the most wilful of delinquents, and it will be no mean step in the right direction if he can be persuaded that such things as the difference between theoretical and actual evaporative power of the fuel he uses have not only a direct bearing on his own balance sheet but on the country's welfare. When it comes to a question of boilers we almost automatically think of Mr. Brownlie, and we cannot deny him the compliment of saying that within recent years he has contributed more of value on this particular subject than any other writer or worker. It is, perhaps, this fact which will scarcely excuse him in the eyes of some for attempting to condense his knowledge within the scope of a booklet; but although at the moment we are concerned with what is no more than a primer we may derive encouragement from the announcement that Mr. Brownlie is in due course to publish something approaching a super-volume dealing with every aspect of the involved practice of boiler operation. As it is, we are given a gossipy little book which deals in simple language and in a rather severely practical style with the essentials of mechanical stoking, the object in view being that of writing down to the boiler attendant as well as providing information of a character such as will interest and educate the works manager. Taken as a whole, the book is a remarkably concise yet complete description of all the more important types of mechanically-operated stokers which may be found in this country, and the author has not been afraid to throw in amongst the descriptions his own opinions as to the respects in which specific plants excel or fail. The busy modern reader has not, perhaps, much time to spend in the fascinating pursuit of historical details, but here we have a remarkably absorbing and almost unique survey of the work of some of the earliest of pioneers. This will well repay reading, if only for the fact that some of the really amazing work carried out prior to 1850 should serve to remind us that we are not quite such a superior generation as we are sometimes apt to suppose.

ALWYNE MEADE

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Business is maintained at a satisfactory level with a fair export business and very steady values.

Acetic Acid, 40% tech.	£24 per ton. Fair inquiry.
Acid Hydrochloric	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw	£21 10s.—£27 per ton makers works according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton
Ammonia Alkali	£6 15s. per ton, spot, delivery. General export demand good, particularly from the Continent.
Bleaching Powder	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	5¾d. per lb.
Potass. Chlorate	3d.—3½d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton d/d.
Soda Caustic 76%	£17—£19 10s. per ton, according to quality.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton carr. paid.
Sod. Bichromate	4½d. per lb.
Sod. Bisulphite Powder 60/62%	£18—£19 per ton according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Nitrite, 100% basis	£27 per ton d/d.
Sod. Sulphide conc. 60/65	About £15 per ton.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	5¾d.—1s. 4d. per lb., according to quality.
Crimson	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow	1s. 11d. per lb.
Barytes	£3 10s. to £6 15s. per ton, according to quality
Cadmium Sulphide	3s. 9d. per lb.
Carbon Bisulphide	£24—£26 per ton according to quantity.
Carbon Black	6¼d.—6¾d. per lb. Market firmer. There is a possibility of legislation to control the amount of natural gas used in production of American black. This may mean higher prices, and manufacturers are not anxious to accept orders.
Carbon Tetrachloride	£56 per ton, drums free.
Chromium Oxide, green	1s. 3d. per lb.
Indiarubber Substitutes, White and Dark	4¾d.—6½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	43s. 6d. per cwt., barrels free.
Lead Hyposulphite	7½d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£15 10s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Sulphur Chloride	3d. per lb., carboys extra.
Thiocarbanilide	2s. 9d. per lb.
Vermilion, pale or deep	5s. 1d. per lb. Much dearer, following rise in quicksilver.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£14 10s. per ton d/d. Demand active.
Grey	£19—£20 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 per ton, according to grade and locality. Market steady.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. „ „ 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 7d. per gall. Unrefined.
Wood Naphtha—	
Miscible	5s.—5s. 3d. per gall. 60% O.P. market stiffer.
Solvent	5s. 6d.—6s. per gall. 40% O.P. Fairly good demand but little offering.
Wood Tar	£5 per ton.
Brown Sugar of Lead	£49 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	7¼d. per lb. Only limited inquiry
Crude 60's	2s.—2s. 3d. per gall. Market steady.
Acid Cresylic, 97/99	1s. 11d.—2s. 1d. per gall. Demand still good. Market firm.
Pale 95%	1s. 10d.—2s. per gall. Steady demand.
Dark	1s. 8d.—1s. 11d. per gall. Steady business.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	10d.—11d. per gall. Very quiet.
Unstrained	8½d.—9d. per gall.
Benzole—	
Crude 65's	10½d.—1s. per gall. ex works in tank wagons.
Standard Motor	1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure	1s. 8½d.—1s. 10d. per gall ex works in tank wagons.

Toluole—90%	1s. 4½d.—1s. 7d. per gall.
Pure	1s. 8d.—1s. 11d. per gall.
Xylol coml.	2s. 3d. per gall.
Pure	3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	10d. per gall. Few inquiries.
Middle Oil / Heavy / Standard Specification	7½d.—9d. per gall. according to grade and district. Market a sh. de firmer.
Naphtha—	
Crude	8d.—9d. per gall. Better demand. Prices firm.
Solvent 90/160	1s. 5d.—1s. 7d.
Solvent 90/190	1s. 2d.—1s. 3d.
Naphthalene Crude—	
Drained Creosote Salts	£6—£7 10s. Demand not so good.
Whizzed or hot pressed	£9—£12 per ton. Not much inquiry.
Naphthalene—	
Crystals and Flaked	£17—£18 per ton.
Pitch, medium soft	52s. 6d.—57s. 6d. per ton. Market steadier.
Pyridine—90/140	22s.—24s. per gall. Demand well maintained. Price again advanced.
Heavy	11s.—12s. Occasional inquiries: little business.

INTERMEDIATES AND DYES

Business in dyestuffs has been restricted since the holidays. An improvement is expected in the new month.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 6d. per lb.
Acid H.	4s. 4½d. per lb. 100% basis d/d.
Acid Naphthionic	2s. 5d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 9d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 4d. per lb. Steady demand.
Acid Sulphanilic	10½d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	7¾d.—8½d. per lb. naked at works.
Aniline Salts	7¾d.—9d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 3d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 19/31° C.	4¾d.—5¼d. per lb. Demand moderate.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline	3s. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£75 per ton.
Diethylaniline	5s. per lb. d/d., packages extra, returnable.
Dimethyaniline	2s. 5d. per lb. d/d. Drums extra.
Dinitrobenzene	9d. per lb. naked at works.
Dinitrochlorbenzol	£84 10s. per ton d/d. Advanced in sympathy with benzol.
Dinitrotoluene—48/50°C.	8d.—9d. per lb. naked at works.
66/68°C.	1s. 2d. per lb. naked at works.
Diphenylamine	3s. 2d. per lb. d/d.
Monochlorbenzol	£63 per ton.
α-Naphthol	2s. 5d. per lb. d/d.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 4½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	5s. 3d. per lb. d/d.
p-Nitraniline	2s. 4d. per lb. d/d.
Nitrobenzene	5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	11¾d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-o-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	4s. 2d. per lb. d/d.
p-Phenylene Diamine	10s. 4d. per lb. 100% basis d/d.
R. Salt	2s. 9d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 6d. per lb. 100% basis d/d.
o-Toluidine	8½d. per lb.
p-Toluidine	3s. 10d.—4s. 3d. per lb. d/d.
m-Toluylene Diamine	4s. 6d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	£49 per ton.
Acid, Acetyl Salicylic	3s. 4d.—3s. 6d. per lb. Quiet.
Acid, Benzoic B.P.	4s. per lb. Larger supplies available.
Acid, Boric B.P.	Cryst. £54 per ton, Powder £58 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	19s.—21s. per lb.
Acid, Citric	1s. 6d. per lb., less 5% for ton lots. Market extremely firm. Upward tendency.
Acid, Gallic	3s. per lb. for pure crystal. Market very steady.
Acid, Pyrogallic, Cryst.	6s. per lb., for 28 lb. lots.
Acid, Salicylic	Prices quoted from 2s. 3d. per lb. down to 1s. 9d. for ton lots. Market rather weak, but tends to improve.
Acid, Tannic B.P.	3s. per lb. Market quiet.
Acid, Tartaric	1s. 1½d. per lb. less 5%. Much firmer with more demand. Upward tendency.
Amidol	9s. per lb. d/d.
Acetanilide	2s. 3d. per lb. for quantity. Very weak.
Amidopyrin	13s. 6d. per lb. Neglected.
Ammon. Benzoate	3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	12s. 6d. per oz. for English make.
Barbitone	15s. 6d. per lb. Weak market.
Benzonaphthol	6s. 3d. per lb. Firmer.
Bismuth Salts	A steady market. Prices according to quantity:
Bismuth Carbonate	12s. 9d.—14s. 9d. per lb.
„ Citrate	11s. 4d.—13s. 4d. „
„ Salicylate	10s. 2d.—12s. 2d. „
„ Subnitrate	10s. 9d.—12s. 9d. „
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides—	Market very firm, although not active. Continental prices advancing.
Potassium	9d.—10½d. per lb.
Sodium	9d.—10½d. „
Ammonium	10½d.—1s. „
Calcium Lactate	Prices vary over a wide range. Good English make can be had from 1s. 7d. to 2s. 3d. per lb.
Chloral Hydrate	3s. 9d. per lb.
Chloroform	2s. per lb. for cwt. lots. Very steady.
Creosote Carbonate	6s. 6d. per lb. Little demand.
Guaiacol Carbonate	12s. per lb. for cwt. lots.
Hexamine	3s. 9d. per lb. for foreign makes. Without much inquiry. Large stocks.
Homatropine Hydrobromide	30s. per oz.
Hydroquinone	4s. 9d. per lb. Foreign make. Much firmer.

Iron. Ammon. Citrate B.P. 1s. 11d.—2s. 3d. per lb., according to quantity.

Magnesium Carbonate—
Light Commercial .. £36 per ton net.

Magnesium Oxide—
Light Commercial .. £75 per ton, less 2½%.
Heavy Commercial .. £26 per ton, less 2½%.
Heavy Pure .. .. 2s.—2s. 3d. per lb., according to quantity. Steady market.

Menthol—
A.B.R. recryst. B.P. .. 70s. Strong upward movement due to disappointing Japanese crop.
Synthetic .. .. 26s.—35s. per lb., according to quantity. English make. Steady demand.

Mercurials .. .. Market rather flat, but prices unchanged.
Red oxide .. .. 5s. 3d.—5s. 4d. per lb.
Corrosive sublimate .. 3s. 6d.—3s. 7d. „
White precip. .. .. 4s. 7d.—4s. 8d. „
Calomel .. .. 3s. 11d.—4s. „

Methyl Salicylate .. 2s. 4d.—2s. 9d. per lb. for carboys. A slightly better market.

Methyl Sulphonal .. 24s. per lb. neglected.

Paraformaldehyde .. 3s. 6d. per lb., without much inquiry.

Paraldehyde .. .. 1s. 4d.—1s. 6d. per lb. in free bottles and cases.

Phenacetin .. 6s. 3d.—6s. 9d. per lb. Shows slight improvement.

Phenazone .. .. 8s. per lb. for cwt. lots. Firmer tendency.

Phenolphthalein .. 7s.—7s. 6d. per lb. In more plentiful supply.

Potass. Bitartrate—
99/100% (Cream of Tartar) .. .. 88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.

Potass. Citrate .. .. 1s. 8d.—2s. per lb.

Potass. Iodide .. .. 16s. 8d.—17s. 5d. per lb., according to quantity. Demand continues.

Potass. Metabisulphite .. 7½d. per lb., 1-cwt. kegs included.

Potass. Permanganate—
B.P. Crystal .. .. 8¾d.—9d. per lb. carriage paid. English make.
Commercial .. .. 8d.—8¼d. per lb. carriage paid. English make.

Quinine Sulphate .. 2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.

Resorcin .. .. .. 5s. 6d. per lb.

Salol .. .. .. 4s. per lb. Very quiet.

Silver proteinate .. 9s. 6d. per lb.

Sod. Benzoate, B.P. .. 3s. per lb. In more plentiful supply.

Sod. Citrate, B.P.C., 1923 1s. 9d.—2s. per lb., according to quantity. Much firmer in common with other citrates.

Sod. Hyposulphite—
Photographic .. .. £14—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.

Sod. Metabisulphite cryst. 37s. 6d.—60s. per cwt. nett cash, according to quantity.

Sod. Nitroprusside .. 16s. per lb. Less for quantity.

Sod. Potass. Tartrate (Rochelle Salt) .. 77s. 6d.—81s. 6d. per cwt., according to quantity. Market quiet.

Sod. Salicylate .. .. Market improved with good deal of inquiry. Powder 2s. 4d.—2s. 9d. per lb. Crystal at 2s. 6d.—2s. 10d. per lb. Flake 2s. 10d.—3s. 4d. per lb.

Sod. Sulphide—
Pure recryst. .. .. 10d.—1s. 2d. per lb., according to quantity.

Sod. Sulphite, anhydrous £27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.

Sulphonal .. .. .. 18s. 6d. per lb.

Tartar Emetic .. .. 1s. 4d. per lb.

Thymol .. .. .. 13s. 6d.—15s. 9d. per lb. for good white crystal from ajowan seed.

PERFUMERY CHEMICALS

Acetophenone .. .. 12s. 6d. per lb.
Aubepine .. .. .. 13s. 6d. „
Amyl Acetate .. .. 2s. 9d. „
Amyl Butyrate .. .. 7s. 3d. „
Amyl Salicylate .. .. 3s. 3d. „
Anethol (M.P. 21/22° C.) 4s. 6d. „ Dearer.
Benzyl Acetate from Chlorine-free Benzyl Alcohol 3s. 3d. „
Benzyl Alcohol free from Chlorine .. .. 3s. 3d. „
Benzaldehyde free from Chlorine .. .. 3s. 6d. „
Benzyl Benzoate .. 3s. 6d. „
Cinnamic Aldehyde Natural .. .. .. 15s. 6d. „
Coumarin .. .. 20s. „
Citronellol .. .. 16s. „
Citral .. .. .. 10s. „
Ethyl Cinnamate .. 15s. „
Ethyl Phthalate .. .. 3s. 9d. „
Eugenol .. .. .. 11s. „
Geraniol (Palmarosa) .. 35s. „
Geraniol .. .. .. 11s.—18s. 6d. per lb.
Heliotropine .. .. 8s. 3d. per lb.
Iso Eugenol .. .. 15s. 9d. „
Linalol ex Bois de Rose .. 32s. 6d. „
Linalyl Acetate .. .. 32s. 6d. „
Methyl Anthranilate .. 9s. 6d. „
Methyl Benzoate .. 6s. „
Musk Ambrette .. .. 52s. 6d. „
Musk Xylol .. .. 19s. „
Nerolin .. .. .. 4s. „
Phenyl Ethyl Acetate .. 12s. 6d. „
Phenyl Ethyl Alcohol .. 16s. „
Rhodinol .. .. .. 57s. 6d. „
Safrol .. .. .. 1s. 10d. „
Terpineol .. .. .. 2s. 9d. „
Vanillin .. .. .. 25s. 3d.—26s. 6d. per lb.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A. .. .. .. 15s. 6d. per lb.
Anise Oil .. .. .. 3s. per lb. Firmer market forward
Bergamot Oil .. .. 18s. 6d. per lb.
Bourbon Geranium Oil .. 35s. „
Camphor Oil .. .. 75s. per cwt.
Cananga Oil, Java .. 10s. 6d. per lb. Advanced.
Cinnamon Oil, Leaf .. 6¼d. per oz.
Cassia Oil, 80/85% .. 9s. 3d. per lb.
Citronella Oil—
Java 85/90% .. .. 5s. per lb. Easier.
Ceylon .. .. .. 3s. 9d. „
Clove Oil .. .. .. 8s. 3d. „ Easier.
Eucalyptus Oil 70/75% .. 2s. 2d. „ Easier.
Lavender Oil—
French 38/40% Esters 26s. per lb.

Lemon Oil ..	.. 3s 4d. per lb.
Lemongrass Oil ..	.. 3d. per oz. Dearer.
Orange Oil, Sweet	.. 13s. 9d. per lb. Dearer.
Otto of Rose Oil—	
Bulgarian ..	.. 27s. 6d. per oz.
Anatolian ..	.. 23s. 6d. per oz.
Palma Rosa Oil ..	.. 19s. per lb. Very short supply.
Peppermint Oil—	
Wayne County	.. 21s. 9d. per lb.
Japanese ..	.. 19s. 3d. per lb.
Petitgrain Oil ..	.. 10s. per lb.
Sandal Wood Oil—	
Mysore	.. 26s. 6d. per lb. Advanced.
Australian ..	.. 21s. per lb.

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C 2, 15 days after the date given.

I. Applications

Basset. Reverberatory furnaces. 9138. Apr. 11. (Fr., 20.4.23.)

Farberei und Appretur Ges. vorm. A. Clavel und F. Lindenmeyer. Centrifugal drying-apparatus. 9415. Apr. 11. (Swiss, 14.1.23.)

Grate. Furnaces or kilns. 9553. Apr. 15.

Gunz. Drying fragmentary etc. material 9419. Apr. 11.

Jones Separation of substances having different density. 9446 Apr. 14.

Lewis Catalysts and carriers therefor. 9654. Apr. 16.

Picken Centrifugal separators. 9744. Apr. 17.

Slatineanu. Carrying out chemical reactions. 9859. Apr. 17 (Swiss, 19.4.23.)

Wiesmann. Evaporating the volatile constituents of solutions, emulsions, etc 9403. Apr. 14.

I.—Complete Specifications Accepted

1333 (1923). Travers and Clark, Ltd. Furnaces. (213,999.) Apr 24.

13,022 (1923). Dupuy. Apparatus for the distillation of solid or liquid substances (198,661.) Apr. 24.

II.—Applications

Donald. Drying peats etc 9653. Apr 16

Gatton Gas-producer plant. 9371. Apr. 14

Griffiths. Apparatus for distilling carbonaceous materials. 9610. Apr. 15.

Londeld, Trenlolm, and Swedris and Co. Production of gas. 9700. Apr. 16.

Wolf. Process of converting oils of high boiling point into those of lower boiling point. 9718. Apr. 16. (Ger., 1.5.23.)

Zollinger Process of increasing viscosity of oils. 9575. Apr 15 (Swiss, 30.4.23.)

II. Complete Specifications Accepted

23,869 (1922). Neath. Manufacture of gas from coal, or from coal and oil. (213,754.) Apr. 24.

33,473 (1922). Heyl. Treating oils. (213,946.) Apr. 24.

780 (1923). Koppers Co. Purifying gases. (207,488.) Apr. 24.

13,022 (1923). Dupuy. See I.

III.—Application

Lomax, Lucas, and V.L. Oil Processes. Production of the lower from the higher phenols. 9786. Apr. 17.

IV. Applications

Bonnard. Manufacture of azo-dyestuffs. 9703. Apr. 16.

Lomax, Lucas, and V.L. Oil Processes. 9786. See III.

Soc. of Chemical Industry in Basle. Dyestuffs. 9594. Apr. 15. (Swiss, 19.4.23).

Soc. of Chemical Industry in Basle, and Schobel. Manufacture of azo-dyestuffs. 9713. Apr. 16.

IV.—Complete Specification Accepted

26,154 (1923.) Soc. Anon. Mat. Col. et. Prod. Chim. de Saint-Denis, Wahl, and Lantz. Manufacture of dyestuffs of the azine group. (206,488.) Apr. 24

V.—Applications

Courtaulds, Ltd., Gilles, Smith, and Templeton. Treatment of cellulose artificial silk. 9696. Apr. 16.

Hay, and Wiggins, Teape & Co. Paper and manufacture thereof. 9386. Apr. 14.

Hohenloher Seifenfabriken Akt.-Ges. Process for washing etc. fabric etc. 9663. Apr. 16.

Hough and Privett. Treating paper and boards. 9571. Apr. 15.

Union Photographique Industrielle (Etablissements Lumiere et Jougla Réunis). Process of nitrating regenerated cellulose films or paper. 9699. Apr 16. (Fr., 23.4.23.)

V.—Complete Specification Accepted

2090 (1923). Scholz. Impregnating fibres, yarns, and fabrics with leather. (192,387). Apr. 24.

VI.—Applications

British Dyestuffs Corporation, Ltd., Fyfe, and Perkin. Dyeing acetyl silk. 9583. Apr. 15

Chemische Fabrik Griesheim-Elektron. Production of fast black shades on fibre. 9855. Apr. 17. (Ger., 17.4.23.)

VI.—Complete Specifications Accepted

9643 (1923). Mate and Pickstone. Bleaching textile fabrics etc. (211,079). Apr. 24.

13,137 (1923). Clark and Co., and McLintock. Mercerising-machines. (214,103.) Apr 24

13,993 (1923). Morton Sundour Fabrics, Ltd., and Kilby. Dyeing cellulose acetate fibres. (214,112.) Apr. 28.

VII. Applications

Ewan. 9621 and 9622. See X

Oesterreichische Chemische Werke Ges Manufacture of persulphuric acid etc. 9604. Apr. 15. (Aus., 22.5.23.)

VII.—Complete Specification Accepted

3173 (1923). Priest. Kilns for burning limestone or the like. (214,022.) Apr. 24.

VIII.—Application

British Thomson-Houston Co., Ltd. Quartz working. 9602. Apr. 15. (U.S., 18.4.23.)

VIII.—Complete Specification Accepted

7763 (1923). Stocker. Treatment of china clay. (214,062.) Apr. 24.

IX.—Application

Levy, and Prodor Soc. Anon. Manufacture of concrete. 9683, 9714. Apri. 16.

IX.—Complete Specification Accepted

3173 (1923). Priest. See VII.

X.—Applications

Bonnafoux, and Stern A.-G. Process to recuperate iron and manganese from slags. 9406. Apr. 14.

Calvert. Furnaces for de-tinning metal plates etc. 9626. Apr. 16.

Ewan. Manufacture of alkali metals. 9621 and 9622. Apr. 16.

Harris. Manufacture of tin-plate. 9778, 9779. Apr. 17.

Jouvenet and Mohr. Treatment of mispickel etc. 9569. Apr. 15. (Fr., 15.5.23.)

Lanz. Refined cast iron. 9676. Apr. 16. (Ger., 23.6.23.)

Lanz. Manufacture of grey cast iron. 9677. Apr. 16. (Ger., 1.12.23.)

Levoz. Furnaces for melting and treating ores etc. 9822. Apr. 17. (Belg., 17.4.23.)

X.—Complete Specification Accepted

6317 (1923). Rodrian. Smelting and electrolysing processes. (194,314.) Apr. 24.

XI.—Applications

British Thomson-Houston Co., Ltd. (General Electric Co.). Electric furnaces. 9805. Apr. 17.

Jones. Storage batteries. 9690. Apr. 16.

Simms (Potter). Electric accumulators. 9834. Apr. 17.

XI.—Complete Specifications Accepted

876 (1923) McBlain. Electrical apparatus for generating ozone. (213,975.) Apr. 24.

2915 (1923). Mather and Platt, Ltd., and Barclay. Electrolysers. (214,020.) Apr. 24.

6317 (1923). Rodrian. See X.

30,713 (1923) Monnot. Electric storage batteries. (214,177.) Apr. 24.

XII.—Applications

Commanditaire Vennootschap Dros & Geb. Tieleman Stoomzeep-Fabriek de Gekroonde Haan, and Tieleman. Production of transparent soap. 9871. Apr. 17.

Hemingway. Manufacture of soap. 9392. Apr. 14.

Zollinger. 9575. See II.

XIII.—Application

Ticka. Manufacture of liquid waterproof coating material. 9474. Apr. 14.

XIII.—Complete Specification Accepted

17,265 (1923). Snape and Mohlman. Varnish. (214,134.) Apr. 24.

XIV.—Application

Naugatuck Chemical Co. Process for treating rubber etc. 9554. Apr. 15. (U.S. 25.6.23.)

XIV. Complete Specification Accepted

15,915 (1923). Marks. Manufacture of hard rubber compositions. (214,124.) Apr. 24.

XV.—Application

Ellenberger und Schrecker. Production of gelatin and glue from chrome leather etc. 9562. Apr. 15. (Ger. 28.1.24.)

XV.—Complete Specification Accepted

2090 (1923). Scholz. See V.

XVI.—Complete Specification Accepted

28,464 (1923). Soc. Chim. de la Grande Paroisse. Manufacture of fertilisers. (210,399.) Apr. 24.

XVII.—Application

Steffen Continuous washing of tricalcium saccharate. 9587. Apr. 15.

XVIII.—Applications

Bexon and Church. Aerating etc. wort in brewing etc. 9853. Apr. 17.

Distillers Co., Ltd., and Meyer. Dehydrating alcohol. 9704. Apr. 16.

Hauser und Sobotka Akt.-Ges., and Stern. Process for production of preparations of diastases etc. 9717. Apr. 16.

XVIII.—Complete Specifications Accepted

1023–1025 (1923) Marks See XX.

XIX.—Applications

Howles and McDougall Insecticides. 9576. Apr. 15.

Whale. Softening water 9665. Apr. 16.

Williams. Preserving fruit and vegetables. 9785. Apr. 17.

XIX.—Complete Specifications Accepted

14,244 (1921). Soc. Chim. Usines du Rhône. Flavouring food with vanillin. (175,589.) Apr. 24.

586 (1923). Marston. Treatment of skimmed milk, soured milk, or buttermilk to separate calcium caseinate or casein. (213,962.) Jan. 8.

XX.—Applications

Cassella und Co., Ges., L. Manufacture of arsenic compounds of the aromatic series. 9590. Apr. 15. (Ger., 17.4.23.)

Distillers Co., Ltd., and Meyer. 9704. See XVIII.

XX.—Complete Specifications Accepted

1023–1025 (1923). Marks (U.S. Industrial Alcohol Co.). Process and apparatus for obtaining alcohols free from water. (213,984–6.) Apr. 24.

1124 (1923). Howards and Sons, Ltd., and Blagden. Making synthetic menthol. (213,991.) Apr. 24.

XXI.—Applications

Dufay. Colour photography. 9727. Apr. 16. (Fr. 11.6.23.)

Union Photographique Industrielle. 9699. See V.

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific number:—*Australia*: Leather (446); Silks (447); Surgical and dental requisites, glassware, scientific instruments, perfumery and oils (448); Drugs (449); Steel (13,520 and 13,521/E.D./E.C./2); *British India*: Tin sheets (Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E. 1); *Canada*: Steel (13,477/E.D./E.C./2): *Chile*: Steel (9649/F.L./E.C./2); *Germany*: Silk (451); *Rumania*: Chemical goods, glassware (457); *Santiago de Cuba*: Leather (469); *South Africa*: Iron, steel, brass (13,539/E.D./E.C.); *United States*: Hardware (460): Pharmaceutical goods, hardware (462); *Uruguay*: Oil (9659/F.L./C.C./2).

Foreign Company News

A company is being formed in Alsace with the help of the Salines Domaniales de l'Est for the manufacture of artificial silk.

JOURNAL of THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 43 NEW SERIES | LONDON, MAY 9, 1924 | No. 19

EDITORIAL

THE deputation from the Federal Council to the President of the Board of Trade appears to have been an interesting occasion. The dyestuff industry is of such vital importance to chemistry and its difficulties have been, and are yet, so acute that our columns have on many occasions been occupied by a consideration of the problem. Mr Sidney Webb spoke of the purpose of the Government and the process of attaining the object in view. It would seem that the general purpose of the Government is to enable chemistry to be studied and practised in this country fully and freely and to maintain a dyestuff industry, so far as it is the business of a Government to maintain any particular industry, in such a state as will conduce to our national prosperity and suffice for the needs of British chemistry. Chemists are already familiar with this aspect of the problem and will be pleased to know that the Board of Trade is fully alive to the importance of the subject. It is when we come to discuss the process that the difficulties arise; the Government, though a large shareholder in the British Dyestuffs Corporation, is not in control of the company, and there are obvious reasons why the President of the Board of Trade should not attempt to act as if he were in control. The task of putting that company into proper order is a considerable one, the responsibility is great, the reward in case of success will be inadequate, the blame in the case of failure will be heavy. In these circumstances we can easily believe that Mr. Sidney Webb might feel some diffidence in attempting to determine the details of a policy on behalf of the Government which other shareholders might prevent him from enforcing.

* * *

If it is practically impossible for the Government to take charge of the situation, it is even more difficult for the Federal Council to make detailed suggestions. The Federal Council has no accurate knowledge of the negotiations said to be in progress and cannot have such knowledge; even if it had the knowledge there are so many factors to be considered that it would be futile for the Federal Council to suggest to the directors of the British Dyestuffs Corporation what steps should be taken to safeguard the shareholders' interests. And yet, by the irony of fate, the whole future of British Chemistry is at stake, and the people who have the greatest power in the matter and the whole responsibility are the company's directors whose business is before anything else to earn dividends for their shareholders, the majority of whom are not chemists and care nothing for chemistry. The Federal Council has probably performed a useful service in putting the chemists' point of view before the Board of Trade, but how anomalous is the situation! It is perhaps better than it was, and certainly the members of the deputation were to some extent reassured by Mr. Sidney Webb; but it is rather singular that the future of British chemistry should at the moment be in the hands of half a dozen men, only one of whom is a chemist, and he has so recently joined the board that he can so far have only just begun to realise the financial and other difficulties which beset the company. If half-a-dozen of the shrewdest of our chemists knew the whole details it might be possible to contrive some scheme which would satisfy both shareholders and chemists, but the details cannot be disclosed to a large body of chemists. That no solution can be found we do not in the least believe; we feel convinced that a satisfactory solution can be found and we hope that it will. Perhaps before it is too late it might be worth while to sit down quietly and consider whether the future of some other vital factor of modern civilisation is dependent upon some limited company over whom neither Government nor anyone else can exercise control and to whom advice must be tendered submissively and cautiously because the lack of accurate knowledge renders boldness out of the question.

* * *

We think that the Federal Council values very highly the invitation by Mr. Sidney Webb to communicate with His Majesty's Government, through the Board of Trade, on the dyestuffs question and are other chemical topics. Many problems of interest and importance arise from time to time, and the Federal Council is not only willing, but anxious to do all in its power to assist this or any future Government to understand and to solve these problems. The Federal Council's most essential function is to speak for chemistry as a whole, theoretical, academic and industrial, and its members are always at the service of the State and of the science they are privileged to represent, and glad to devote their time and energy for the benefit of

the community. Politicians necessarily tend to be either individualistic or socialistic in their outlook. Chemists are in most respects essentially individualistic, but in the organisation of chemistry and in the unselfish way in which chemical knowledge and skill are made available for the community, they show a democratic spirit which deserves commendation from the most rigid and austere of the Socialists. A great opportunity for chemists to show their devotion to the community of chemists is now being developed in connexion with Chemistry House, and this scheme will afford abundant scope for both individual effort and social advancement. We shall return to this particular topic at a later date.

* * *

Those who were present at the meeting of the London Section on Monday evening must have listened with a great deal of interest to the accounts that were given of the use of bauxite as a refining agent. It is, indeed, fascinating to attempt to account for the way in which bauxite can remove both colour and sulphur compounds from petroleum products with ease and regularity, without any loss other than that due to mechanical disintegration. The preparation required consists solely in roasting the mineral to remove the moisture and in grading it to a specified fineness. Material that has lost its activity through use can be recovered with efficiency undiminished simply by steaming and roasting again. On considering the troubles that arise in the refining of petroleum by purely chemical means, the importance of such a simple and reliable method can readily be understood. Bauxite is by no means a mineral new to science, as it was first described by Berthier in 1821, and named " beauxite " by Dufrénoy in 1847 and " bauxite " by St. Clair Deville in 1861. The name is derived—and the derivation should decide the controversy that arose some years ago regarding the correct pronunciation of " bauxite " —from Les Baux or Beaux, a locality near Arles in the South of France, where the mineral was first found. Deville, of course, originated the well-known process for producing pure alumina from bauxite for the manufacture of aluminium. Indeed, a great many of the names associated with the development of the aluminium industry appear to be foreign, but this country can claim Faraday as the first to isolate the metal, and now we owe the development of bauxite as a refining agent to British science. One wonders whether this new use for bauxite will in any way reduce the supplies required for other purposes. Cobalt, for instance, was found to possess many advantages as a material for electroplating, but its use for this purpose became economically impossible, owing to the great development of high speed alloys of which it is a constituent. Such competition is unlikely to affect bauxite, however, as we were told that there is no relation between its chemical constitution and its efficiency as a refining agent; indeed, the development of this new application should prove a stimulus to its production within the Empire, as material unsuitable for the production of alumina may prove highly efficient as a refining agent.

SOME SCIENTIFIC ASPECTS OF PUERING AND BATING *

By C. E. PICKARD, A.I.C.

This paper is an attempt to co-ordinate numerous scattered publications on the problems of puering and bating, rather than to present an additional contribution of practical research. Puering and bating, though differing practically in many ways, are identical in theory, and most of the following paper therefore applies to both processes.

The term bating, applied to the softening of skins before tanning, is generally understood to be derived from the French " abattre "—to knock off, *e.g.*, to bate a jot of one's pretentions. Puering has been stated to be derived from the French verb " puer " —to stink, and the smell of a fermenting puer liquor certainly suggests that some relationship may exist between the two words. It seems more probable however, that the English word " puer " is a form of " pure," from the French verb " épurer " —to cleanse. Puering is in fact largely a cleansing process, in which hair roots, sweat glands, pigments, etc. (collectively known as " scud ") are removed; and it is only in recent times that the more specific chemical reactions such as the breaking down of elastin and " interfibrillary " substances have been appreciated.

The bating process appears to have been confined originally to the treatment of the heavier classes of skins with fermenting infusions of hen or pigeon manures, while for a similar process applied to the lighter skins (goat, sheep, etc.) and in which dog manure was used, the term puering was allotted.

The scientific achievements in the study of the puering or bating process, however, and the consequent introduction of efficient enzyme bates, which are used on practically all classes of skins, have so confused the two words, that the " bate " seems likely to live by its association with the manufactured enzyme bates, leaving the " puer " and its unpleasant associations to become extinct.

The Action of the Bate

The study of the bate was undertaken successfully first by J. T. Wood, of Nottingham, who summarised the results of his researches as follows :—" The action of the dog dung bate is due to the action of enzymes in combination with organic compounds, amines, and salts of ammonia. The character of the principle enzyme in the dung is a proteolytic one, and resembles the trypsin contained in the pancreatic juice. Photomicrographs illustrating bating tests by J. T. Wood and showing elastin are given on the opposite page; the sections (×92) are 20 μ thick and are stained by the Weigert method.

These conclusions have not only been verified by subsequent researches, but provide the basis for the manufacture of the dog dung substitutes—Pancreol bate and Oropon—whose successful use confirms the laboratory findings of Wood, and provides incidentally a standard material for the elucidation of related problems.

* Read before the Nottingham Section on March 26.

The Criterion of Bating

There still exists however, a good deal of uncertainty as to what is the criterion of a well-bated skin, and the casual reader of current literature or patents on the subject cannot but be perplexed with the tangle of theories and new evidence which is constantly brought forward.

Wood's conclusions simply state to what bodies the action of the bate is due. The criterion of bating is a related but distinct study. To the practical bating man, the skins are bated when they have reached the right "feel," and by long experience and a kind of instinct, the correct condition of the skins can be judged. But it is of interest to go rather deeper into the question, for though bating was judged by "feel" and by the qualities of the finished leather long before it became a subject for scientific investigation, and will probably be judged

A.—Calf-skin section, before bating

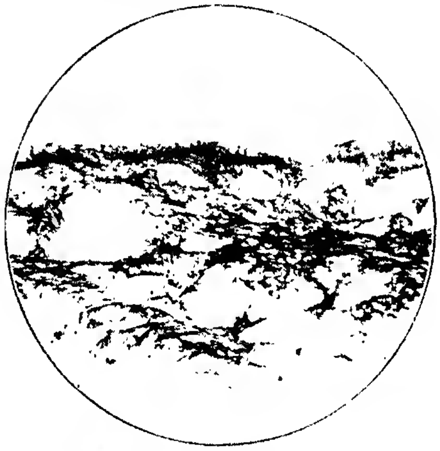
by those standards long after the whole process has been expressed in formulæ, it is always of value to be able to express in terms of definite chemical and physical change, the real mechanism of the bating process.

Systematic experiment has, in fact, aimed at distinguishing what is essential from what is unnecessary or harmful in the bating, so that having found the precise changes which must take place in the constituents of the skin, we may judge how these changes may be best accomplished.

Principles of Research

Before reviewing the work of our chief investigators, I will indicate briefly the principles which have been employed in researches of this kind. The changes which occur are exceedingly complex, involving both chemical reactions and those of organised and unorganised ferments, and it is a matter of no little difficulty to say what proportion of the observed effect should be ascribed to each of these agencies.

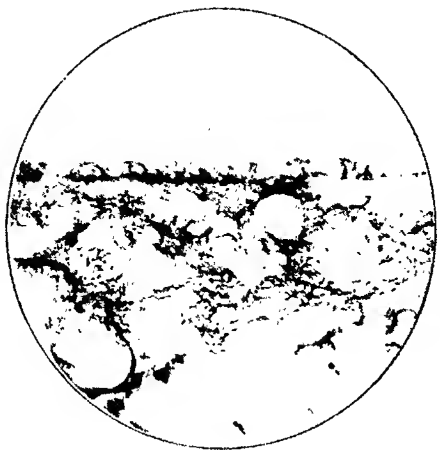
A method based on the biochemical analysis of skins before and after bating was carried out by Rosenthal,[1] who was able to conclude that elastin is digested in bating. This method is, however,



B.—Calf-skin section, bated with Pancreol 5A for 2 hrs.

limited by our incomplete knowledge of the chemistry of skin substances. The second method, by which much information of value has been obtained, is histological, which treats of the minute structure of the tissues and organs of animal bodies.

Every part or organ of the body, when separated into minute fragments, or when examined in thin



C.—Calf-skin section, bated with Pancreol 5A for 20 hrs.

sections under the microscope, is found to consist of certain tissues or textures, which differ in their arrangement in different organs, but each of which exhibits characteristic structural features. By these features, it is possible to recognise a number of the constituents of the skin[2]. The method of microscopic

identification has become very specialised, with a highly developed technique, and by the aid of selective stains[3] it is possible to observe clearly many of the structural changes to which the falling of the skin is due.

An interesting attempt to give an actual mechanical or numerical value to the effect on the skin of the puering and deliming processes is that of Wood, Sand and Law,[4] for details of which the original papers must be consulted.

There are also useful mines of information in estimating electrometrically the hydrogen-ion concentrations[5] of bating solutions and skin substances, but the results provide interesting data related rather to the physical control of bating liquors than to the structural nature of the skin.

Researches on the Effects of Bating

Turning now to the more recent reports on bating, it will have been gathered that the results of bating reach much further than the mere removal of lime[6], and involve the formation of products of enzyme action[7].

In a series of interesting contributions to the *Journal of the Society of Leather Trades Chemists*, on the "Physiology of the Skin," A. Seymour-Jones has published in detail the results of his investigations on the structure of animal skins, and the changes which take place in them during their conversion into leather. He demonstrates the actual effect of bating as compared with mere deliming, by the carrying out of experiments on sheep grains. One portion of the sheep grain split was bated with Pancreol, and one half delimed only with acetic acid, both being afterwards tanned with sumac and dried out. The author examined the leather and reported as follows:—

1. Pancreol-treated Grain

Quality. A fine example of what a skiver should be for sound leather.

Colour.—Pale cream.

Texture.—Mellow, with the soft stretching quality desired.

Under the Microscope

By transmitted light. The hairholes appear clean and clear in every instance. There is no cementing effect in any single instance. The separation of the membrane follicle walls is complete. The papillary membrane is clean, clear and intact, with evidence of separation among the fibres constituting the membrane, clearly showing that something has been digested away. The transmitted light is a bright yellow. By *reflected light* a distinct yellow colour has been shown.

After this leather had been wet back and set out, an examination

By transmitted light showed: The hairholes exhibit considerable enlargement; the papillary areas show long flat-shaped ridges; at the end of each the membrane follicle appears. The whole slide gives the impression of extensibility and cleanliness of structure. The transmitted light is a light canary colour.

Under reflected light the leather showed a light canary colour and an almost translucent sheen, giving the impression of mellowness.

2. The Delimed Grain

was now examined and showed:—

Quality.—The ideal qualities exhibited by the Pancreoled grain were missing.

Colour.—Of a brownish hue.

Texture.—Somewhat harsh, the grain being tucked in small nodules.

Under the microscope.—The leather showed by *transmitted light*: No clear hairholes: each one appears to be glued up. The holes are smaller than in the Pancreoled grain. The papillary areas are pinched up by contraction into ridges resembling sharp cut rugged mountain tops with sealed hairholes on their peaks. The slopes are saucer-shaped, again illustrating contracting influences at work. On the whole surface the view is as though the grain membrane had dried without being properly tanned. It looks horny. The *transmitted light* is a very dark orange colour. By *reflected light* the colour is a peculiar elephant grey.

After being wet back and set out, an examination showed:—

By transmitted light.—The hairholes are opened more, but all are, more or less, blocked by the basal part of the membrane follicle. The glueing effect is present, though in a lesser degree than before setting out. The papillary membrane is less rugged in appearance, yet the horny character of the membrane remains present. The *transmitted light* is an orange colour. By *reflected light* the leather showed a light grey shade of colour, and a sheen giving a horny appearance to the membrane.

The author states that: The impression created by comparing the foregoing pieces is that the contracting influence is due to undigested elastin, which unless digested, does not tan similarly or even comparably to collagen.

For detailed accounts of elastin, collagen and other skin substances, the reader is referred to "Principles of Leather Manufacture," by H. R. Procter, and to the following papers: "The Chemistry of the Skin. by A. Seymour-Jones (*J.A.L.C.A.*, 1916, Vol. XI, p. 41); "Biochemical Studies of Skin," by G. J. Rosenthal (*J.A.L.C.A.*, 1916, Vol. XI, p. 463), and "The Chemical Constituents of Skin," by A. Seymour-Jones (*J.S.L.T.C.*, 1922, Vol. VI, p. 261). To present a survey of skin substances, regarded as far as may be possible as chemical individuals, is beyond the scope of the present paper.

In "The Mechanism of Bating[8]," J. A. Wilson concludes that bating consists of two distinct parts. (*a*) Reducing the skins to a condition of minimum swelling; (*b*) digesting the elastin fibres present in the outer layers of the skin.

In "The Removal of Elastin During Bating[9]," R. H. Marriott criticises the findings of Wilson, and describes experiments which show that whilst elastin is digested by an enzyme bate, the removal is not a fundamental of the process.

In "The Properties and Action of Enzymes in Relation to Leather Manufacture[10]", J. T. Wood

states: "Although the elastin is completely removed from the skin bated by trypsin for a sufficiently long time, about 24 hours, in practice the bating is not continued to this point, but is carried on only for about 2—6 hours. The elastin is only partly removed in this time, but the skins made good leather. The writer believes that it is not necessary or even desirable for the whole of the elastin to be removed or dissolved in order to let the skin down, but that it is sufficient for the elastin fibres to be broken up or weakened, in order that the desired suppleness may be obtained."

In "The Hydrolysis of Collagen by Trypsin[11]" F. L. Seymour-Jones gives an account of the action of trypsin on the collagen constituent of the skin, and showed very definite digestion (after a preliminary passive period of 24 hours) of the collagen by the trypsin. That none, or practically none, of the collagen is removed in commercial bating is due to the fact that no concentrations of trypsin as were used in these experiments are ever likely to be present in ordinary bate liquors.

In a "Note on the Hydrolysis of Collagen by Trypsin[12]," R. H. Marriott criticises a number of the features of the dissertation by F. L. Seymour-Jones. The paper contains much valuable information.

In "The Action of Trypsin on Collagen[12]," Stiasny and Ackermann conclude that the effect of trypsin on collagen depends essentially on the preliminary state of the latter, notably on its degree of swelling and on other conditions of the experiment. The misconceptions on this fact explain the contradictory information which is found in the literature dealing with the subject.

I shall now refer to "Some Observations on the Histology of Bated Skins[14]," by the Rohm and Haas Co., Inc., Philadelphia. The original papers were illustrated by some excellent photo-micrographs, obtained in collaboration with Dr. Gies, of Columbia University. The experiments carried out and the histological results are summarised as follows:—

(a) Goatskins were bated, in parallel experiments, (1) with a natural dog-manure bate, and (2) with a manufactured enzyme (or "artificial") bate. Clippings of the skins were prepared for histological examination, and the bulk of the skins subsequently finished into leather.

Results.—The histological examination revealed that the elastin was by no means completely removed, either in the case of the dog-manure bate or the artificial bate. All the skins when finished gave normally good leather in every respect.

(b) Calf skins were bated in parallel experiments, (1) using an infusion of chicken manure, and (2) using a manufactured enzyme bate. It was considered that calf skins and goat skins present more or less the two extremes of required enzyme action, at least so far as skins for shoe leather are concerned.

Results.—The amount of elastin still present after bating was considerable, and did not vary greatly between the enzyme bate and the chicken manure series.

(c) Goat skins were bated, in parallel experiments, with the object of determining whether there is any difference between a dung bate employing bacterial enzymes and an artificial bate using pancreatic enzymes, but with different types of delimer.

Results.—In every way the deliming was complete. The swelling completely disappeared, and the skins were absolutely normal in their fallen or flaccid condition. The finger-print test was normal, and the porosity for air also, and no difference whatever was observed in this respect between artificial and dung bates.

The papers conclude: "It remains to be seen if there is any action going on, due to the presence of enzymes, that has not yet been made visible under the microscope. I imagine that the substance, usually referred to as 'interfibrillary substance,' is distributed as an unformed jelly or viscous liquid in the fibres of the skin, and subject to change in every step of the manufacturing process in the beamhouse. . . ."

". . . From the point of view of the practical tanner, there seems to be little doubt that the removal of such interfibrillary substance, which, along with hair-roots, sweat glands, etc., is generally described as 'scud'[15], does constitute one of the most important functions of the bating process. The phenomenon of the scud flowing out from the skin has not received so much attention as we should wish, and as seems to be indicated by the very necessity of the operations in the actual manufacture of leather. As an example may be taken the bating of lambskins in the manufacture of glove leather. If an attempt is made to scud these before bating, the scud adheres to the knife in the form of a substance of cheese-like consistency, whereas when scudding is conducted after bating, the scud flows freely from the skin, in a consistency only little greater than that of water."

"From the histological standpoint, I imagine that the scientific explanation of the bating operation, and of the scud, would present quite a few difficulties, since to my knowledge no selective stain has been found for the probably very heterogeneous mixture constituting the cementing or interfibrillary substance."

A. Seymour-Jones[16] speaks of the fibre bundles as being united by a soft filamentous substance of considerable tenacity and elasticity, known as "areolar tissue." Such tissues surround many organs of the body.

Schafer[17] says that Mall looks upon the intercellular or ground substance as living substance (exoplasm), and as bringing all the cells of the tissues into continuity. He regards the whole structure, cells and ground substance together, as constituting a continuum, the fibres being laid down or formed by chemical transformation in the exoplasm.

The Remaining Problem

The principal remaining problem now is what happens to this interfibrillary substance. Chemically, the matter if not simple, because both collagen and hyaline, when overlimed, are chemically changed, so that they are capable of being attacked by trypsin.

Some information might be got from the composition of the scud[18]. An analysis of a scud from English sheep grains showed only 0·164 per cent. of nitrogen, equivalent to about 1 per cent. of skin substance. The fat content was 7·19 g. per litre.

Wood also found that a sample of scud taken from machines which had been scudding sheepgrains out of puer, contained 24·62 g per litre of total solids :—

Inorganic	4·01
Free fat	7·95
Organic matter (not fat)	12·66

The last item, of course, contained the organic matter of the dung, in addition to the interfibrillary substances.

Eberle and Krall[19] analysed the fatty matter which adhered to men's knives (after the goods had been puered) in scudding lamb skins for gloving work. They obtained the following results :—

	%
Water	29·7
Fat (largely wool fat)	42·0
Fatty acids combined with lime	6·6
Albuminous matter soluble in water	3·8
Hair and insoluble albuminous bodies	14·4
Ash (containing 57% CaO)	3·5

Attempts have also been made to estimate the cementing substances by analyses of puers before and after the skins have been put through Here the results are influenced by the amount of nitrogenous matter brought into solution from the puer itself, while if an artificial bate is used, a considerable correction is necessary for the products of enzyme autolysis of glandular matter in the bate, whose solubilities are partly dependent upon the nature and relative concentrations of neutralised and free deliming agents.

With regard to histological examination, it has been suggested by Jerome Alexander[20] that the use of the ultra-microscope and darkened field might reveal features of the interfibrillary and other substances which are invisible in the illuminated field of the ordinary high-power microscope. The same authority also criticises the use of stains and alcohol in the preparation of skin sections, since the structure of the colloidal substances may be changed by treatment with such active reagents.

Procter[21] states that the cement substance seems to be removed by liming. If this is so, then there cannot be any effect on it in the bating.

It may at least be said definitely that the skin substances which are dissolved in a puer or bate, are hydrolysed almost as completely as gelatin is when the latter is boiled with dilute sulphuric acid.

Future Progress

Instead of proceeding finally to summarise the present state of knowledge of the science of bating, which I trust has been conveyed in this paper, I am tempted to make a few observations to illustrate the futility of generalising on a subject so involved. Early in the paper, I referred to "Enzymes," which are conveniently defined as organic "catalysts." Both the words however, explain nothing, and merely serve opportunely to cover an obscure idea which is not fully understood. In passing back from the word to the idea, it becomes easy to believe that "the subjective abstraction has an objective existence," or that because there is a word, something real must lie behind it.[22]

The same might also be applied to skin substances, many of which cannot strictly be regarded as distinct chemical entities, but as related forms of protein matter, differing slightly in elementary composition, each differently modified by events in the history of the skin, its source, its post-mortem changes, and its treatment in the beamhouse, and which exist together in a natural and elaborate structure which nerve matter, hair roots, bacteria, and the factors of life itself have combined to build.

But far be it from me, in emphasising the incompleteness of our knowledge, and in hinting that we are only on the fringe of the cause and effect of bating, to admit that the phenomena are beyond us. "Nature presents to our senses a panorama of phenomena co-mingled in endless variety, so that we are sometimes overwhelmed and dazed by the apparent complexity of empirical knowledge. It is the work for the intellect to educe the elements of sameness amidst diversity, and to see differences amidst apparent identity."

By such means did the old-time puerman, aided by empirical knowledge and instinct, regulate his puer liquors and prepare his skins for leather; by such means has it been possible to eliminate much of the uncertainty of the puering or bating process by the introduction of manufactured and standardised enzyme bates; and by such means, aided by logically conceived experiment, will the scientific aspects of the problem be correlated and finally understood

A NEW METHOD FOR EMPTYING CARBOYS.

By J. ADAM WATSON, A.C.G.I., F.I.C.

As there are many occasions when it is necessary to remove a definite weighed quantity of liquid from a carboy, and in view of the risks attending the obvious method of pouring when the liquid is either corrosive or gives off dangerous fumes, the following method is suggested in the hope that it may be of use to any who have been faced with the same difficulties as the author.

Having to handle both concentrated sulphuric and nitric acids in quantities which though considerable did not permit of employing large storage tanks, the possible risks were continually brought to our notice. Carboys are on the whole rather treacherous things; when full their weight renders them liable to slip as it is only possible for two persons to co-operate efficiently in their handling; further, when, in weighing a quantity of acid, it is desired to stop pouring suddenly, there is great liability for the liquid to splash out of the mouth. All these considerations led us to try to devise some safe and simple way of handling these containers.

The most obvious method of inserting two tubes into the carboy through an air-tight bung and blowing air through one tube into the carboy is difficult of application owing to the varying size and condition of the carboy necks. Also, it is subject to the grave risk of the carboy bursting under the pressure. Eventually an adaptation of this method was evolved which, as far as we know, has not been used.

The carboy is placed in a box provided with an air-tight door and a pipe passes through the box into the carboy and delivers into a tray standing on the platform of a weighbridge. Air is blown into the box and the liquid is thereby forced out of the carboy up the pipe to the tray, where it is collected and weighed. The box is placed at a convenient height above the ground, so that the carboy may be readily placed inside, after which the door is closed. The pipe which is to deliver the liquid passes through a packing-gland in the top of the box so that it may be drawn up out of the way when it is desired to change the carboy. The packing-gland permits this movement of the pipe without impairing the air-tight properties of the box. By connecting this pipe by means of a union with the remainder of the pipe line to the tray the whole system is made simple and is easily worked. An air exhaust is also fitted to the box in order quickly to reduce the pressure inside to that of the atmosphere. The tray in which the acid to be weighed is collected is fitted with a short outlet pipe which delivers into a funnel large enough to cope with the flow of liquid from the tray and this funnel in turn is connected by a pipe with the tank in which the acid is to be mixed. While the tray is being filled the outlet is closed by a plug provided with a long handle so that it may be readily removed. The whole system is set up in such a way that the end of the delivery pipe from the carboy is at a higher level than the liquid in the carboy, thereby preventing any syphoning action while the pipe line is laid, so that there is a fairly steep slope both to the carboy and to the tray. As both sulphuric and nitric acid have to be dealt with, the sliding pipe is made of aluminium and the remainder of the pipe line of iron piping. The tray is of wood lined with thick lead and the plug is of lead fitting into a lead seating.

The advantages of this system are fairly obvious. In the first place, as there is no difference of pressure between the inside and the outside of the carboy, there is no liability to bursting. It is a simple matter to place the carboy in position, and all danger of splashing may be overcome by tying a piece of stout paper over the mouth after the removal of the bung. This paper will offer no obstacle to the insertion of the sliding pipe, but will prevent any liquid issuing from the carboy while it is being moved. By using the air exhaust in the box the flow of liquid from the pipe can be stopped instantly so that it is easy to weigh a definite quantity by the use of the weighbridge. Although there is still a considerable amount of fuming when handling strong nitric acid, yet, by this system, there is no necessity for the workmen to come into the region of the fumes. This system has been worked for about two years without any trouble and with considerably less inconvenience than attended the old method of emptying the carboys by hand.

THE ADVANTAGES OF MECHANICALLY SLAKED LIME

(From a Correspondent)

It is very remarkable that even in the chemical industries a large proportion of the lime used is still of the hand-slaked variety, whilst small users of lime, not only chemical works in general, but builders for example, have not yet realised the advantage of mechanically-slaked lime. Unquestionably in this respect we are behind the Continent, where the sale of pure dry slaked lime in bags is a flourishing industry and the material finds an astonishing variety of uses. From a purely chemical point of view, mechanically-slaked lime has the great advantage that it is a pure product, practically 100 per cent. calcium hydrate, containing no free lime (CaO) and no unslakeable material, whilst it is in the form of such an excessively fine and uniform powder that it is almost semi-liquid in mechanical properties and possesses pronounced lubricating qualities. Further it can be supplied without difficulty either entirely free from moisture, or with any pre-determined and definite amount, such as the 1 per cent. required, for example, in chlorine absorption and the manufacture of bleaching powder.

The machines used for slaking lime are of different types, but one general principle largely employed is to slake the lumps of quicklime with jets of water in a revolving screen chamber enclosed in a large outer casing. The lime as it is slaked falls to a dust of dry hydrate which passes through the perforations into the outer chamber whilst all stones and unslakeable material are left behind. The large

volume of steam given off, representing about 5 per cent. of the total weight of the lime, is caught in a jet condenser, and the water, heated nearly to boiling point, is used for slaking through the jets in the revolving screen. The slaked lime dust is then conveyed along in the inner chamber, being thoroughly agitated and mixed in the process, with the result that no trace of free oxide is left in the product, which is discharged at over 200° F., in an absolutely uniform and excessively fine powder of almost chemically pure hydrate $Ca(OH)_2$. Extra water can, of course, be added if desired, so as to give any desired moisture content to the finished product. From the point of view of the chemical or other works where large quantities of lime have to be slaked the process is almost a revolution in comparison with the laborious, objectionable, expensive, and clumsy method of slaking lime by hand, spreading it out over a large area of floor, and obtaining a product which contains lumps, all the stones and other unslakeable products, and generally an irregular content of free unslaked lime as well.

The advantages are equally important for users of lime, who obtain a pure and definite product which can be mixed with water exactly as required without any waste and which will keep indefinitely and is packed in bags. In the building trade, for example, this would save at least 50 per cent. of the lime used as compared with the present antiquated method of digging a hole at great expense and slaking lime in it, the greater part of the lime being not only never used, but also always exposed in a wet condition to the air, and absorbing carbon dioxide, for example.

The advantages of mechanically slaked hydrated lime are very apparent in connexion with water softening by the lime-soda process. The constancy of composition and freedom from impurities together with the mechanical condition of the product are of the utmost importance in this process and lead to regularity and ease of control.

Another very valuable use of mechanically-slaked lime which is now beginning to attract attention in Great Britain is in concrete mixing. If slaked lime is added to the extent of about 8--16 per cent. of the weight of the cement, the advantages in the finished concrete are very pronounced. Thus, for example, the plasticity of the mass is increased, so that less water can be used for mixing, giving therefore reduced segregation and less tendency to cracking, whilst the resulting concrete is much more dense and nonporous, and the waterproof qualities are increased to a very remarkable extent. These results are obtained because mechanically-slaked lime is in the form of very fine particles which act as void fillers, and because lime has more lubricating action than other materials of the same class

Prof. M. T. Bogert, professor of organic chemistry at Columbia University, has been elected chairman of the U.S. National Research Council committee on chemical research on medicinal substances.

DEPUTATION FROM THE FEDERAL COUNCIL TO THE BOARD OF TRADE

Mr. Sidney Webb, the President of the Board of Trade, received on May the 6th a small deputation from the Federal Council for Pure and Applied Chemistry to discuss the position of the Dyestuffs Industry; Sir Sydney Chapman, Mr. Percy Ashley and Major Church, M.P., were also present. Sir William Pope introduced the deputation, which included Prof. W. P. Wynne, the President of the Chemical Society; Prof. H. E. Armstrong, a past President of the Chemical Society; Prof. J. F. Thorpe, Honorary Treasurer of the Chemical Society; Mr. H. E. Coley, Chairman of the Chemical Industry Club; and Dr. S. Miall, Honorary Secretary of the Federal Council; and explained that the Federal Council consisted of representatives from the Chemical Society, the Society of Chemical Industry, the Association of British Chemical Manufacturers and all the other organisations connected with English chemistry. He urged that the dyestuff industry was essential to the progress of organic chemistry, including pharmaceutical and many other branches; that the progress of research in organic chemistry was inseparable from research in the dyestuff industry and that no steps should be taken which would allow the control of advance to revert to German hands. he pleaded that any arrangements made between the British Dyestuffs Corporation and the German Interessen-Gemeinschaft should respect the original intention of making the dyestuffs industry here free from German influence or domination. Prof. W. P. Wynne referred to the great development of chemical inquiry which had taken place in this country, especially in organic chemistry, during the last few years, and stated that if German discoveries in dyestuffs were to be relied upon for the British dyestuffs industry an avenue would be closed to a number of highly trained and efficient chemists. Prof. H. E. Armstrong said that whereas formerly it was necessary for a chemist to receive training in research in Germany, it was now possible for him to acquire as good or even better training in this country; that it was essential to attract into chemistry men of ability who could advance a science which was of great importance to every manufacturing industry, to agriculture and medicine, and that every possible encouragement should be given to the promotion of chemistry here. He discussed the serious effect on the natural indigo industry of India caused by the cessation of research in this industry.

Mr. Sidney Webb in replying stated that the matter was one in which politics played no part. All were agreed as to the purpose; it was the process of carrying this out which was difficult. The present Government, and indeed all Governments, recognised the necessity of promoting scientific research and supplying opportunities and freedom for carrying it on. He was convinced that the research work in the dyestuff industry should be done here by British trained chemists, but the method of securing this was not easy. As regards the proposed agreement he pointed out that the Government was not a party to the negotiations, but he was sure that no

agreement would be concluded which was not consistent with the original purpose of the British Dyestuffs Corporation. He agreed that there could be no monopoly in research in this industry and he realised that the dyestuffs industry was essential to the progress of chemistry as a whole. He hoped that what he said would to some extent reassure the deputation and that the Federal Council would continue to communicate with the Board of Trade on this or any other chemical topic.

Sir William Pope thanked the President of the Board of Trade for receiving the deputation and for his sympathy with their views.

May 13. INSTITUTION OF PETROLEUM TECHNOLOGISTS, at the Royal Society of Arts, John Street, Adelphi, W.C. 2, at 5.30 p.m. "The Geology and Oil Measures of South-East Persia," by R. K. Richardson, A.R.C.Sc., M.Inst.P.T.

May 14 and 21. BRITISH EMPIRE EXHIBITION. Conferences on "Heredity as the Basis of National and Industrial Efficiency.

May 15. CHEMICAL SOCIETY. Ordinary Scientific Meeting at Burlington House, Piccadilly, W. 1, at 8 p.m. "The Bromo-derivatives of 1-Methylglyoxaline and the Constitution of 'Chloroxalmethylin,'" by I. E. Balaban and F. L. Pyman. "Synthesis of Amygdalin," by R. Campbell and W. N. Haworth, and "Reactivity and Radiation. The Photochemical Union of Hydrogen and Sulphur," by R. G. W. Norrish and E. K. Rideal.

May 21. ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C. 2, at 8 p.m. (Trueman Wood Lecture) "The Outlook in Chemistry," by Sir W. J. Pope, K.B.E., D.Sc., F.R.S.

Members of the Society of Chemical Industry are invited to attend the meeting of the Organic Industries Group of the Société de Chimie Industrielle, to be held on May 13, in the Rooms of the Société Française de Photographie, 51, Rue de Clichy, Paris, when the following papers will be read:—(1) "The Synthesis of '309' and the changes brought about in the therapeutic action of the derivatives of this family by chemical modifications" (with kinematograph illustrations), by Monsieur E. Fourneau, and (2) "The Thickening of Paint," by Monsieur Ch. Coffignier

SOCIETY OF CHEMICAL INDUSTRY

ANNUAL GENERAL MEETING, 1924

PATRON: H.M. THE KING

In accordance with the provisions of by-law 68 notice is hereby given that the Annual General Meeting of the Society of Chemical Industry will be held in the Arts Theatre, The University, Liverpool, on Wednesday, July 9, 1924, at 11 a.m.

The following is a Preliminary Programme of the meetings to be held in Liverpool on July 9-12 inclusive.

WEDNESDAY, JULY 9.—*Morning*: Council Meeting. Annual General Meeting in the Arts Theatre, the University. Presidential Address by E. Frankland Armstrong, D.Sc., F.R.S.; *Afternoon*: Business Session in the University. Visit to White Star Liner "Cedric," and tea on board by invitation of the White Star Line. *Evening*: Reception and Dance at the Town Hall by invitation of the Right Hon. The Lord Mayor of Liverpool (Arnold Rushton, Esq.).

THURSDAY, JULY 10.—*Morning*: Messel Memorial Lecture by the Right Hon. Viscount Leverhulme, in the Arts Theatre, the University, and presentation to the Lecturer of the Society's Messel Medal for 1924. Visit to the works of Messrs. Joseph Crosfield & Sons, Ltd., Warrington. Luncheon by invitation of the Directors. *Afternoon*: Inspection of the Works. *Evening*. Annual Dinner of the Society at the Midland Adelphi Hotel.

FRIDAY, JULY 11. *Morning*: Business Session in the University. Luncheon at the Midland Adelphi Hotel, by invitation of the Chairman and Directors of the United Alkali Co., Ltd. Visit to a Works of the United Alkali Co., Ltd. *Evening*: Dinner at Lady Lever Art Gallery by invitation of the Chairman and Directors of Messrs. Lever Brothers, Ltd.

SATURDAY, JULY 12.—Visit to Lake Vyrnwy. Inspection of Liverpool Corporation Water Works.

A detailed programme will be sent later to every member of the Society.

Members are asked meantime to note that the railway companies in Great Britain (except the Metropolitan and London Electric Railway Companies) have agreed to issue tickets at the ordinary single fare and one-third for the double journey to passengers travelling to attend the meeting. The tickets will be available from July 8 to 14.

DEATHS

Evans, Lincoln W. (elected 1923), of the South Eastern Agricultural College, Wye, Kent. Lecturer in Chemistry. On March 6, 1924.

Gall, John B. (elected 1905), of 49, Glenlyon Road, Eltham Park, London, S.E. Chemist. On March 27, 1924.

Houlehan, Dr. Arthur E. (elected 1919), of Messrs. E. I. du Pont de Nemours and Co., Wilmington, Del., U.S.A. Associate Director of the Jackson Laboratory. On March 11, 1924.

McAlley, James (elected 1916), of 193, Broomloan Road, Govan, Glasgow. General Manager. On February 27, 1924.

Tucker, Alex. E. (elected 1894), of 59, Cambridge Street, Birmingham. Metallurgical Chemist. On March 28, 1924.

MANCHESTER SECTION

Dr. H. Levinstein presided over the meeting held on May 2 at the Textile Institute.

A resolution of condolence with the family of the late Dr. G. H. Bailey, Senior Demonstrator in Chemistry in the University of Manchester, was passed.

"A Note on the Detection of Persulphate in Flour and a recent Bleaching Agent for Flour," was then read by Mr. J. Miller, F.I.C.

Mr. Miller stated that the usual reagent for detecting per-salts in flour was a solution of benzidine in alcohol. His suggestion was, however, to use an aqueous solution of potassium iodide. A recently manufactured bleaching reagent for flour, sold under the name of "Novadelox B," consisted of a mixture of benzoyl peroxide and acid calcium phosphate. Benzoyl peroxide was an oxidising agent and a powerful antiseptic, but its use internally had been discontinued owing to its poisonous action on the blood. The general properties of benzoyl peroxide were reviewed, and the detection of benzoyl peroxide in flour was described as follows:—The flour is mixed into a paste with a solution of potassium iodide, and heated on a boiling water-bath. The presence of benzoyl peroxide is indicated by the appearance of dark spots. This test will indicate the presence of half an ounce of the salt in a sack of flour (280 lb.). Slides were shown illustrating the potassium iodide test for persulphates, and there were also exhibited pastes of flour containing benzoyl peroxide in the proportion of half an ounce per sack of flour (280 lb.) or an actual proportion of 1 in 9000.

In his paper "On Insulin," Dr. A. Renshaw, D.P.H., stated that the history of research on diabetes showed how very near several investigators had been to obtaining an active pancreatic extract resembling insulin. Even the method of ligaturing the pancreatic duct used by Banting, to produce atrophy of all except the Islets of Langerhans, had previously been used by other workers in an endeavour to obtain the secretion of the Islets of Langerhans. Zuelzer had nearly approached Banting's discovery in 1908, and this semi-failure showed the importance of not giving up a piece of research work until the truth was finally established. Once Banting and his co-workers had demonstrated that such an extract could be obtained, the finer methods of blood analysis now available allowed them to overcome the pitfalls into which other workers had fallen, and to show that the extract was potent in reducing the sugar content of blood. The next step consisted in translating these facts, by clinical application, into a recognised method of treatment. After this, the subsequent difficulty of manufacture of insulin on the large scale had to be faced. The generosity of Banting and his co-workers in presenting the patent rights in this country to the Medical Research Council could not be overrated. The Council had assisted chemical firms in their endeavours to produce insulin on the large scale. The manufacturing methods employed were then dealt with in detail. As much as 10 million units of insulin per week could now be produced by one firm alone, or sufficient for approximately 7000 persons.

Another feature was the manner in which the cost had been reduced to bring the product within the reach of the poor man. After seeing the ingenious methods in use by one large manufacturer of insulin, it would come as no surprise if the cost was still further reduced. Insulin, however, was not a cure for diabetes. It was rather like an artificial limb which enabled a man to walk after one leg had been lost. It had to be used as long as life lasted, and it required a great deal of care on the part of the patient who uses it.

It was with no sense of disrespect for the very fine achievement of Banting when he stated that the prevention of diabetes was better than a cure. In this respect he would like to repeat even more firmly an obeservation made two years ago, *e.g.*, that the cause of diabetes was bacterial in origin, and that its onset could be assigned to the activities of the *B. Amyloclasticus Intestinalis* described two years ago by Mr. Fairbrother and himself. Reasons were given to show how the ferment arising from this organism could disturb the function of glycogen formation; and how such disturbance was translated into terms of an increased secretion from the Islets of Langerhans followed by exhaustion of the cells. In other words, the disturbed metabolism met with in diabetes had its origin in the bacterial fermentation present in the intestines. Such an action must be specific in its neutralisation of the secretion from the Islets of Langerhans. There were very few bacteria which could act upon glycogen, which was the chief substance concerned in diabetes. The ferment arising from the bacillus mentioned could, however, act upon this substance, and it appeared probable that there was some stereochemical relationship between the antiferments or antitoxins produced against this bacillus and the insulin or ferment produced by the Islets of Langerhans. The ferment produced by the latter assisted in building up glycogen from glucose; the ferment produced by the bacillus broke down glycogen. Furthermore, it had been shown that the liver cells most concerned in the storage of glycogen from glucose could absorb the bacillary ferment.

From a consideration of these facts it appeared that the prevention of diabetes offered the main hope. Once the pancreatic islets had been exhausted, insulin appeared the only treatment along passive lines. A few early cases might be improved if the absorption of bacillary ferment could be checked. The organism occurred amongst bad potatoes, and Prof. Fowler had recently described a similar organism occurring in bad rice. The significance of this fact in relation to the higher percentage of diabetes amongst the Hindus could not be over-rated. A similar organism occurred in fermenting maize, producing an alcohol. Possibly this fermented-maize drink was responsible for the presence of diabetes in a non-civilised race like the North American Indians. This bacillus had been found in approximately three out of every four cases of diabetes examined by him.

SHAWINIGAN FALLS SECTION

A meeting was held at the Cascade Inn on March 31. Dr. Skirrow, presiding in the absence of the chairman, introduced Mr. H. Freeman, who gave an address on "A Few Problems for Industrial Research in Canada." Discussing the ever-present fuel problem, he pointed out that although the extreme west and east of Canada are well supplied with coal, the great industrial regions of Quebec and Ontario are dependent on American supplies. Large fields of lignite occur in the prairie provinces, but are practically undeveloped because the lignite, in order to become a satisfactory fuel, must be dried, carbonised, and briquetted. No really satisfactory binder for briquetting had yet been found, but the material of the required cheapness and physical properties seems to lie in the bituminous sands of the Alberta river valleys, awaiting only some well-organised industrial research to apply it to what may well become a great industry. Turning to the metallurgical industry, the speaker pointed out the essential differences between Canadian and American deposits of gold, silver, copper, lead and zinc. Whilst the latter have usually been concentrated by Nature and are leachable, the former exist as sulphides and contain large quantities of materials which must be removed. Roasting and smelting processes are expensive, and the enormous quantities of iron are usually wasted. More iron than is used on the West Coast is mined in British Columbia in the form of copper ores carrying iron and thrown on the dump. Research on electrolytic and other methods of separation could probably make this iron available for use, and at the same time cheapen the production of copper.

In connexion with the old problem of sulphite waste liquor, well-known wherever there is a paper mill, mention was made of the possibility of recovering wood oils by evaporation and distillation of the waste liquor, and the use of these oils for preserving timber and in the oil-flotation process for concentrating low grade ores. As to the odoriferous soda-pulp process, aside from the problem of making its smell less overpowering, there is that of supplying the large quantities of sodium sulphate required in producing the smell. Excellent natural deposits of Glauber's salts occur in Saskatchewan, and need only a little engineering to work out satisfactory methods of evaporation and handling to supply the Canadian Kraft mills, which now import $1,500,000 worth annually. In closing, the author pleaded for greater encouragement, either by private enterprise or by the Government, to the chemist and engineer in these and other problems so important to national prosperity.

A lively discussion followed, and after a vote of thanks to the speaker the meeting adjourned.

R. M. Howe, Vice-President of the American Ceramic Society, and at one time engaged on research on refractories as senior industrial fellow in the Mellon Institute of Industrial Research, has died at the early age of 30.

CHEMICAL SOCIETY

Presiding at an ordinary scientific meeting held on Thursday, May 1, at 8 p.m., Prof. W. P. Wynne reminded Fellows that the Faraday lecture would be delivered by Prof. R. A. Millikan at the Royal Institution on Thursday, June 12, at 5.30 p.m., instead of June 26 at 8.30 p.m. as previously announced; admission would be by ticket obtainable from the Assistant Secretary. Other announcements were to the effect that applications for grants from the Research Fund must be received by June 2, and that in the interests of economy the list of Fellows would not be printed this year.

Mr. H. T. S. Britton read the following two papers:—

The electrometric titration of chromic acid using (a) *the hydrogen electrode, and* (b) *the oxygen electrode.*

Chromic acid has been titrated electrometrically with sodium hydroxide by means of the hydrogen electrode and also the oxygen electrode. Some of the essential points to be observed in the preparation of hydrogen electrodes for use in presence of chromic acid, chromates and nitrates have been recorded. Evidence has been adduced to show that chromic acid dissociated as a normal dibasic acid. The dissociation $H_2CrO_4 \rightleftharpoons H^{\cdot} + HCrO_4'$ is almost complete in dilute solution, whereas the dissociation of the hydrochromate ion, thus $HCrO_4' \rightleftharpoons H^{\cdot} + CrO_4''$, is extremely small. The second dissociation constant is $4 \cdot 4 \times 10^{-7}$ at 18° C. The use of the oxygen electrode as an indicator of both hydrogen-ion concentrations and end-points has been demonstrated by comparison with the hydrogen electrode. It has been shown that the dibasicity of chromic acid, as H_2CrO_4, accounts for some of the reactions of chromic acid and its salts.

Chromates of thorium and the rare earths. Part II. The chromates of lanthanum, praseodymium, neodymium, and samarium.

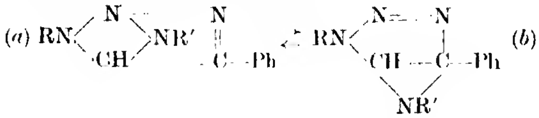
Lanthanum, praseodymium, neodymium and samarium form an isomorphous, yellow, difficultly soluble series of chromates of the general formula $M'''_2(CrO_4)_3, 8H_2O$. The variation in their solubilities shows their importance in processes of fractional precipitation with potassium chromate. The tendency to form sparingly soluble double chromates is marked in the cases of lanthanum, praseodymium and samarium. Lanthanum forms the salt $K_2CrO_4.La_2(CrO_4)_3,6H_2O$. The addition of potassium chromate to aqueous salt solutions causes the precipitation in the case of (*a*) lanthanum, of the simple chromate, if the excess of precipitant is small; (*b*) praseodymium, of the simple chromate; (*c*) neodymium, of a mixture of simple and basic chromate, (*d*) samarium, of an indefinite basic precipitate.

Investigations (with Miss H. W. Carnelley) were described by Mr. P. K. Dutt:—

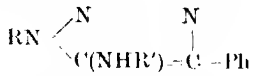
*Imino-dihydro-*1 : 2 : 3*-triazole. Part II. Intra-annular migration of the dyad type and intra-nuclear tautomerism without migration.*

The reaction between 1 : 4-diphenyl-5-chloro-1 : 2 : 3-

triazole and *p*-toluidine on the one hand and that between 1-*p*-tolyl-4-phenyl-5-chloro-1 : 2:3-triazole and aniline on the other lead to the formation of the same two products, *a* and *b*, which are tautomeric and have the general formulæ,

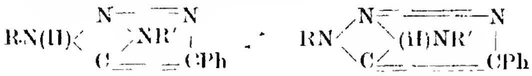


In alcoholic hydrochloric acid either of these tautomerises into another form, such as



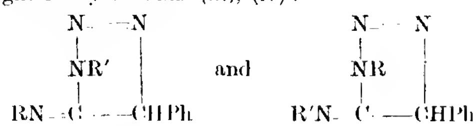
which yields N-nitroso and acetyl derivatives.

Prof C. K. Ingold thought that the work was capable of interesting extensions to other heterocyclic nuclei, but doubted whether the interpretation offered had been fully proved. It was to be expected from analogy with Diels's addition reaction that (i) and (ii) would be *directly* interconvertible (a form of ring-chain tautomerism), so that it was unnecessary to postulate an intermediate four-membered ring :



(i) (ii)

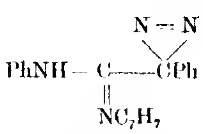
Further, the isomerides with the properties of anils might really be anils (iii), (iv) :—



(iii) (iv)

and not the dicyclic bodies supposed. The difference in their ease of substitution might be due to the blocking up, in one of the isomerides, of the para-position of the benzene ring involved (R = phenyl, R′ = *p*-tolyl) The reactions iii⇌i and iv⇌ii were of a well-known type, so that it appeared possible to interpret all the results on comparatively simple and well-recognised lines.

Replying, Mr. Dutt remarked that a mechanism leading to the formation of an intermediate phase such as



could not be supported, since the well-known reaction, whereby a substance of the type  when treated with sodium ethoxide is converted into $EtO\cdot CH_2\cdot CO_2Et$ with evolution of nitrogen, did not take place. Further, the substances (*a*) and (*b*) did not yield nitrosoamines with nitrous acid in acetic acid, and therefore could not have the suggested alternative structure.

Prof. D. R. Boyd discussed experiments (with Mr. F. J. Smith) on :—

The formation of triphenylmethylphosphinic acid from triphenylmethoxyphosphorus dichloride.

The acid obtained from triphenylmethoxyphosphorus dichloride by the action of alcoholic potash (Boyd and Chignell, *T.*, 1923, 123, 813) has been investigated further. It is shown to be a phosphinic acid, with the formula $(C_6H_5)_3C\cdot PO(OH)_2$; and not a phosphorus acid ester of triphenyl-carbinol, as originally supposed.

During the hydrolysis of the phosphorus chloride, therefore, a molecular rearrangement must occur, analogous to the change which di-ethyl sulphite undergoes under the influence of aqueous potash :

iii

$$(C_6H_5)_3C\cdot O\cdot PCl_2 + 3KOH + C_2H_5\cdot OH$$

v

$$= (C_6H_5)_3C\cdot P{\overset{\nearrow O}{\underset{\searrow OK}{—}}}OC_2H_5 + 2KCl + 2H_2O$$

iv vi

$$O=S{<}^{OC_2H_5}_{OC_2H_5} + KOH = {}^{O}_{O}{>}S{<}^{C_2H_5}_{OK} + C_2H_5\cdot OH$$

Triphenylmethylphosphinic acid is also obtained, in small quantity, when the mixture of products formed by the action of phosphorus trichloride on triphenyl-carbinol is treated with water.

ACADÉMIE DES SCIENCES

On March 31, Monsieur Termier spoke on the changes undergone by the diamond at high temperatures. These changes, as shown by Friedel, affect the zones of birefringence. Monsieur Bogitch discussed the formation of the solid masses which sometimes clog crucibles, explained by a change of composition affecting the fusibility. According to Monsieur Audibert, explosives decompose in two stages, and the conditions of this decomposition suggest application in "fiery" mines in taking measures to ensure safety. Monsieur Lebeau described an electrical vacuum furnace with a device for measuring temperatures accurately, and consisting of tungsten heated by an electrical current of several hundred ampères, and surrounded by a cover of fused silica bathed in water so as to prevent heating. Monsieur Lebeau, who is an old pupil of Moissan, has obtained, in this way, temperatures up to 2400° C. In a paper by Monsieur E. André it appears that phocenic acid extracted from whale fat, and first isolated by Chevreul, is identical with the valerianic acid derived from the root of valerian.

On April 7, Monsieur L. Gentil discussed the magnetic anomalies observed by Lazarev in the Koursk district of Russia, and stated that these had been found of less intensity to the south of the band previously described. The conclusion drawn, that the anomalies showed the presence of deposits of magnetic iron, had been partly verified by borings. A note by Monsieur A. Mayer on the oxidation of the plant cell in relation to the moisture content of the protoplasm, was communicated by Monsieur Molliard, and Monsieur D'Arsonval communicated a note by MM. Ménard and Foubert, on the curative action of ultra-violet rays on certain diseases. Prof. Le Chatelier then presented a paper by Monsieur Audibert on the decomposition of nitroglycerin and the Abbé Sanderans described a process which he has originated for making mixed organic oxides containing alcohol and benzyl groups.

EVOLUTION IN CHEMICAL INDUSTRY

At University College, Nottingham, on March 29, the third Sir Jesse Boot Foundation Lecture, entitled, Evolution in Chemical Industry -Aniline Dyes," was delivered by Mr. H. Lambourne, B.A., B.Sc., F.I.C., in the absence, through indisposition, of Prof. S. F. Kipping, D.Sc., F.R.S.

The lecturer first dealt briefly with the natural colouring matters, some of which; *e.g.*, Tyrian purple, madder purple and indigo, were of hoary antiquity. The four main products obtained by the distillation of coal tar, namely, benzene, toluene, naphthalene and anthracene were then discussed. Some account of the life and work of the founder of the coal-tar industry—Sir William Perkin—was given, and the rapid development of the industry from 1856. Thus, aniline (from benzene) and toluidines (from toluene) produced the Rosanilines (Verguin 1859); the Azo dyestuffs (Griess, 1860) were obtained from aniline and similar basic substances; the phenols (from benzene) and phthalic anhydride (from naphthalene) gave rise to the Phthaleins (Baeyer, 1871); anthraquinone (from anthracene) was converted into alizarin (Perkin, 1869, Caro, Graebe and Liebermann, 1869); anthranilic acid (from naphthalene) with chloracetic acid gave rise to indigo (Heumann, 1890, 1897).

Numerous experiments were performed, and a number of slides shown, which illustrated the subject as outlined above.

In conclusion, two contributory factors were given as to why Germany had so largely captured this industry which had its origin in England, and its early development in England and France. The first was the co-operation which existed in Germany between industry and the universities and colleges; the second was the fact that all the German industrial concerns were scientifically controlled, and not directed by business men who occasionally perhaps referred to scientific experts.

Reference was also made of newspaper misrepresentation of scientific matters; which prevented the public from understanding and appreciating the importance of chemistry and chemists to national prosperity.

CORRESPONDENCE

INTERNATIONAL LANGUAGE FOR SCIENTISTS

Sir,—As the original remarker, allow me to express first the pleasure I have in Professor Patterson's partial approbation of the idea and, secondly, why I do not agree with his modification.

Unfortunately, I must confess that I am neither a Latin scholar nor an Esperantist, so, on the actual detailed claims of the rivals, I am not qualified to offer an opinion. However, I am quite alive to the historical value of Latin and I am thoroughly aware of what I want for my purpose in industrial science.

There is one instance where Latin escaped the slaughter of the Renaissance—I mean in Medicine. Here, Latin is used in many countries, so it should be a living example of an international language, but, when I was sick, my medical adviser left me a prescription with the directions thereon:—"Coch. Mag. in aq t.i.d. pc." The dispenser had no trouble in labelling the bottle "A tablespoonful in water, three times daily after food," but could a French or German dispenser have done it. I do not think so, besides, is not the historical beauty somewhat faded in the generality of medical Latin?

Again, when I read old Beckman's "History of Invention" or any History of Agriculture, I always find that Latin names were very lax. For example Magnesia, Manganese, Magnet (Fe_3O_4) are all derived from the same source.

Then probably 99 per cent. of the phenomena or "sense impressions" we desire to express have no true Latin equivalent. The words require to be invented and put into the old frame.

My conception is that science requires a new tool, a language capable of expressing any idea with the utmost clarity, and, at the same time, to express or show minute differences—a language, in fact, which will bear the same relation to other languages that the calculus bears to euclidian geometry.

Most of the roots are ready made, and in international use, as, ion, sol, names of elements, plants, bones, stars, etc.: all that is required is a simple extensible framework, wherein irregularities are impossible. This would be an enormous boon to coming generations, and, as we have burned their coal, ruined their physique, and, in general, played the mischief with their inheritance—we do owe posterity something.

The advantages are apparent—scientific books, papers, patent specifications and lectures would be given in one language. There would be no trouble, say, if a Chinese scientist came to Europe. He could lecture in every country and the audience would grasp his finest meanings. The language bar would be exterminated and, with it all, the petty jealousies concomitant therewith.

The one thought is time. It takes an effort to start a thing which will take twenty or more years to be of service, but it often takes three generations to build a business for private gain, so surely we have enough initiative and staying power combined with the organising ability and altruistic sentiment required to carry out a scheme like this, if it is worth

doing. At present, we must admit that "The intelligentsia has failed." Failed dismally in Germany, Russia and France. We are laughed at both by the capitalist and the worker. We are dreamers and visionaries who cannot translate our words into deeds. Scientists ought to lead the world's forces. They ought to direct all progress, but they do not even follow the leaders. They sit still and complain of neglect.

In résumé, I think a new language "made to order" is better for our purpose than Latin, as it is a machine we want, easily learned, quickly written and free from difficult sounds, capable of expressing new conceptions and fine shades of meaning.

I think the scheme would be of great service in the future, as it would have considerable effect on international relations, simplify scientific training, and cause a greater circulation of scientific ideas.

The scheme is altruistic and any effort expended on it would be for the benefit of our successors, rather than for our own good.—I am, Sir, etc.,

CAREY LAW

April 21, 1924

A REPLY TO PROF. PATTERSON'S SUGGESTION TO USE LATIN AS AN INTERNATIONAL LANGUAGE FOR SCIENTIFIC LITERATURE

Sir,—In the preface to his classic on Bridge Construction, Jeremiah Head explains that he calls his work "De Pontibus" because, having reached his 58th year, and having spent the better part of his early life in learning Latin, he feared that he might die without ever being able to make any use ot the study of many years. Now, when I read Professor Patterson's letter suggesting that Latin might be used as the International Language among scientists I, like Jeremiah Head, said to myself, "here is an opportunity of making some use of my early life's work," which, also, was an endeavour to learn Latin. But on looking at the matter more dispassionately, does it not appear that by taking this attitude Prof. Patterson and I would be rather imitating the fox that lost his tail? We, like a good many others, have doubtless wasted the bulk of our youth in learning Latin, and consequently have suffered more or less all our lives through having, perforce, neglected the study of useful subjects; but this is really no excuse for advocating that future generations should be submitted to a similar handicap.

As regards an international language for scientific literature, is it not obvious that any nation can make their language international by making their scientific literature indispensable? Is it not also an extremely humiliating fact that although the greater part of the civilised world, and almost the whole of the scientific world, speaks and writes English, nevertheless it is not possible for a chemist to arrive at the forefront of his profession without an intimate knowledge of German? The reason for this is not far to seek. Plainly, we have no works of reference that can compare with Beilstein[1], Gmelin-Kraut[2], Stelzner[3], and, to a lesser extent, the Zentralblatt; and now that all these works are being perpetuated under the auspices of the German Chemical Society, the pitch of completeness to which they are being brought makes them the most important part of any scientific library.

On reviewing these facts, therefore, does it not appear that English would automatically become the international language for scientific literature, if only the English-speaking nations could bring themselves to produce literature of a standard of perfection and utility equal to that now produced by the Germans?

The problem remains how this could be achieved, but surely our Chemical Society could do what the German Chemical Society has done?

1. Our abstracts are unquestionably very much better than they used to be, and if they could be drafted more with a view to enabling one to work from them without having to refer to the original papers, it would be quite possible without much modification to at least equal those appearing in the Zentralblatt.

2. If these abstracts were accompanied by a really full and exhaustive index (the entries for which should be supplied by the abstractors), it would be quite practicable without much additional work for that index to supply all the information for which we now have to turn to Stelzner in respect of Organic work and for which there is at present no exhaustive record in respect of Inorganic, thus placing us, in this latter respect, ahead of our German compeers.

3. With reference to Friedlander,[4] which deals with Organic patent literature almost entirely, the want for this could, I think, readily be met by modelling the abstracts of patents which appear in this *Journal*, so that they should always contain sufficient of the essence of the patent to enable the operations therein described to be carried out without reference to the original; this, in nearly every case, would be met by the inclusion, in full, of one of the examples described.

4. With regard to a complete text-book giving a summary of the world's knowledge in respect of every Organic compound which has ever been analysed, it is difficult to see how anything other than a translation of Beilstein would meet this case, and the same applies—in a lesser degree—to Gmelin-Kraut for the Inorganic side of the science.

It will doubtless be pleaded that the question of funds is the stumbling-block in such herculean undertakings, but might not this be met by eliminating the over-lapping which at present exists between the English and American Chemical Societies, both of which issue a series of abstracts of the same papers in the same language? If these Societies were to come to some arrangement similar to that which has already been come to between this *Journal* and that of the Chemical Society (London), in respect of pure and applied science whereby we, for the sake of argument, abstracted all the Organic work and the Americans abstracted all the Inorganic, then the saving thus arrived at should enable each Society to issue abstracts and indexes on these two

[1] Beilstein, Handbuch der Organische Chemie.
[2] Gmelin-Kraut, Handbuch der Anorganische Chemie.
[3] Stelzner, Literatur-Register der Organische Chemie.
[4] Friedlander, Fortschritte der Teerfarbenfabrikation.

subjects equal to, if not superior to, anything produced by the German Chemical Society (*i.e.*, the Zentralblatt and Stelzner), whilst with judicious and economical organisation it should be possible to produce an English "Beilstein" by, say, the Chemical Society, London, and an English (American) "Gmelin-Kraut," say, by the American Society.

With literature of this degree of perfection in a language spoken by more than half of the civilised world could there be any question but that English would become the International Scientific Language?

I am, Sir, etc., O. SILBERRAD

Buckhurst Hill, Essex

April 23, 1924

PUBLIC OPINION OF SCIENCE

Sir,—On several occasions recently you have remarked upon the time spent by chemists (and other scientists) in attending committee meetings, and in reading papers to one another, and on their lack of interest in outside affairs; also on the slight recognition accorded to science and to men of science, in the political and commercial worlds, and by the public generally. The one set of circumstances appears to be correlative to the other, on the surface at least.

With your permission I would like to touch upon one aspect only of this question. The majority of the general public gather most of their information and a great part of their opinions from the newspapers. They do not read books, except, perhaps, light fiction. The newspaper editor, therefore, seeks to publish what he believes his readers would like, and to a lesser degree what he would like his readers to believe. Every important newspaper in addition to the ordinary sub-editor has its own "foreign" editor, its "city" editor and its "sports" editor, with special writers on law, literature, drama, motoring, chess and even bridge. But who ever heard of a newspaper having a special writer or contributor on science?

Scientific matters, inventions and discoveries are handed over to the junior reporter apparently to be "written up," and a fine hash he often makes of them If one were to tell one of the bright young men who serve Reuter's or Harmsworth's that Charlie Chaplin had been engaged as full back for Aston Villa, or that Georges Carpentier had entered for the bantam-weight championship he would, not unnaturally, think his informant an escaped lunatic; also, he *might* look askance if he were told that G. B. S. had been "hung," artistically, of course, at the Royal Academy, or that Wells (H. G., not the Bombardier) had written a one act farce. But tell him that Prof. Humperdunck, of Berlin, has discovered how to produce petrol from sea-water, and the glad tidings will be cabled all over the world forthwith. On any question of sport, politics, commerce and so forth, the reporter goes to seek authentic information from what we may call headquarters, but it is not worth while in the case of science, and probably the reporter has no idea where scientific "headquarters" are.

Within the last few months it has been cabled out to South Africa that a German professor (it is always a German or an American who can do these wonders) had found out how to make coal out of paving-stones, and that another G. P. had discovered how to turn blue asbestos into white. Early this year someone calling himself Hendrik van der Walt "spoofed" all the Dutch newspapers in the Transvaal by informing them that the Johannesburg Chamber of Mines had planted *thousands of acres of macaroni* in the Northern Transvaal, and that *the crop was already sprouting*. This tit-bit might have been too steep (as the Americans say) for English newspapers, but one never knows.

The Chamber of Mines has not yet tried to grow macaroni, but it has founded a news bureau, a publicity department, from which reliable information (as reliable that is as the mining magnates see fit) is broadcasted by printed circulars to all the newspapers in the Union, and it is astonishing how many of these journals make use of the ready-made articles thus supplied. They are written in a popular and interesting style, and save a lot of time and trouble to the country editor, who is often leader-writer, reporter, proof-reader and business manager rolled into one. Among all the scientific bodies in Britain, could not some similar bureau of information be organised to disseminate reliable news of scientific progress, and thus serve to educate public opinion and stimulate public interest. Quite a number of private manufacturers issue periodical circulars broadcast (some very attractively got up) for their own selfish ends; the proposed scientific publicity bureau should have far more material to choose from, and its objects would be to a large extent altruistic.

Prieska, South Africa

AN INTERNATIONAL LANGUAGE FOR CHEMISTRY

Sir,—In his article in *Chemistry and Industry*, of April 11, Prof. Patterson has very ably set out the case for Latin as the chemist's international language. He has, however, treated Esperanto more slightingly than it deserves. The problem of an international auxiliary language has been considered by a committee of the British Association, which reported in 1921 that an invented language such as Esperanto gave the most satisfactory solution. It was unanimous in its conclusion that the advantages of Latin were outweighed by its disadvantages. The introduction of Latin would necessitate its supplementation by a considerable number of new words (a glance at the Pharmacopœia is interesting in this connexion), whereas, in Esperanto, a very full vocabulary exists at the present time ready to the hand of the scientist. It was suggested that Latin was relatively difficult to the average man; Esperanto, on the other hand, being so simple that "three weeks of intensive study under a good instructor would enable a class of teachers to master the essentials and acquire a fluency which is seldom gained in French or German after twelve months' study abroad." It appears reasonable to suppose that by use of such a language valuable results might be obtained in

considerably less than the twenty years suggested by Prof. Patterson. Esperanto has received support from such bodies as the League of Nations, the French Académie des Sciences, and various Chambers of Commerce. The International Pharmaceutical Federation is now considering the adoption of Esperanto nomenclature. The utilisation of this language in the service of chemistry seems worthy of serious consideration.—I am, Sir, etc.,

QUALIFIED AND UNQUALIFIED CHEMISTS

Sir,—The first paragraph of Mr. Bonsfield's letter may have a certain amount of force in answering the arguments of those who hold no recognised qualifications, but his whole letter ignores one important point. Why should the fact of passing the examination of a society—or in many cases admission without examination—count for more than a university degree. The universities of this country have a record and history behind them beside which the Institute with less than fifty years of life appears very young. Probably it is suffering from the inexperience of youth.

If the Institute intends to make itself the arbiter as to who shall and who shall not be called chemists it must really embrace all who by experience, training and/or position are considered chemists. If it does not, the employers of labour will not recognise the Institute's classification any more than they do now.

I suggest that in addition to the present qualifications the following might be added to meet the cases brought forward in the *Journal* :—

A.I.C. should be conferred upon those

1. Possessing B.Sc. (Pass), provided the applicant has been engaged in industry as a chemist for (say) five years
2. Possessing any degree above B.Sc. if taken in chemistry.
3. Possessing no degree, but having been engaged in industry for (say) ten years and receiving a salary above, say, £400 a year.

A man's value in industrial chemistry is surely his value to his employer, and by fixing a salary limit for unqualified men (which sum need not be published) a satisfactory line of demarcation may be found.

One word more; by insisting on passing B.Sc. with honours in chemistry the Institute proclaims that an industrial chemist should have a knowledge of chemistry and little else. Personally I have found physics and mathematics of more value than chemistry. All industries are not alike. In a case such as dyeing no doubt the Institute is right. It is from my own experience that I have suggested the first of the above new qualifications.

Regarding the suggestion to call ourselves chemors, may I make one? Why not refer to pharmacists as chemists as is done at present and denote ourselves by the more ancient spelling "chymists"?—I am, Sir, etc.,

FUEL TECHNOLOGIST

ATOMIC STRUCTURE

Sir,—I regret that owing to a clerical error in my letter to you in the issue of April 25 the word "not" has crept into the sentence relating to a suggested third quantum number for electron orbits in atoms. The third quantum numbers referred to *are identical.* with Bohr's third quantum numbers, and consequently also identical with Sommerfeld's "ground quantum numbers" derived from consideration of X-ray spectra.—I am, Sir, etc.,

GOVERNMENT SURPLUS STOCKS

Sir,—On the 1st of April considerable publicity was given in the Press to a function which marked the termination of the late Disposal and Liquidation Commission. Since that date references to that event have been made, and it would appear that an erroneous impression has been created in the minds of the public generally, in that they have concluded that the whole of the Government Surplus Stocks have been liquidated.

There is, in fact, a large and valuable stock of machinery etc. remaining for disposal, for the sale of which we were by special contract in June last appointed agents to the Government. Whilst we have already realised a large proportion of that stock, we have yet millions of pounds worth of extremely useful stores of almost every description still to be sold on behalf of the Government.

In the interests of the public it is most desirable that these facts be brought to their notice, since the revenue obtained from the sale of these surplus stores is a contribution to the National Exchequer.—We are, Sir, &c.,

L'UNION INTERNATIONALE

Sir,—As members of the Society of Chemical Industry our principal article of Faith is the interchange of scientific and technical knowledge, as is testified by all our activities. Your editorial reference to the harmfulness of nursing our wrath to keep it warm pleases me. In Bernard Shaw's recent play "St. Joan," one of the characters aptly remarks that the courage of Faith will always outlast the courage of Wrath, and I am glad that this truth is borne out in the change in tone of your comments on the question of inviting Germans to the Union Internationale. Dr. Fritsche's letter shows that he, too, is ceasing to nurse his wrath.

The Council of the Society of Chemical Industry has never run the Society on a political basis, but

has served its members by promoting the interchange of scientific knowledge, and in spite of every political upheaval our *Journal* has continued to give equal publicity to all foreign contributions to our science.

Once the question of Reparations is settled there can be no reason except the nursing of our wrath for withholding a frank invitation to our German and Austrian chemical colleagues to take part in the International Conferences.

Most of those who believe in the ultimate triumph of intellect also believe that warfare amongst civilised communities will some day entirely cease. It is clear to them that otherwise civilisation will prove self-destructive, and intellect will fail to dominate.

By promoting common intellectual interest in science we are doing our best to hasten the day of Peace Further, a clear vision of the just history of the cause and conduct of the War is more likely to result from our coming together to discuss intellectual and scientific topics with, than by our remaining aloof from, our German neighbours.—I am, Sir, etc.,

FRANCIS H. CARR

Hampstead

A CORRECTION

In the letter on "Legislation in Relation to Chemical Industry," published in the issue of May 2, on p. 466, col. 2, 25th line from the bottom, in place of "(R)" substitute "(Mr. Kenneth Swan)," the remaining references (P) and (R) to be unchanged.

PERSONAL AND OTHER ITEMS

Royal Visit to the Chemical Hall at Wembley

On May 2, their Majesties the King and Queen, accompanied by the Duke and Duchess of York, paid an informal visit to the Exhibition at Wembley. After visiting the Palace of Engineering they made a tour of the Palace of Industry, including the Chemical Hall The Royal Party was received at one of the entrances and conducted through the Hall by the General Manager of The Association of British Chemical Manufacturers. They spent some time in the Scientific Section where the interesting Exhibits by Sir John Russell representing Agriculture, and by Sir Robert Robertson showing Explosives were noted A copy of "Chemistry in the Twentieth Century" caught the attention of the King, who had previously accepted a specially-bound copy for his own library. Some ancient Egyptian dyed fabrics were also displayed and, as a companion exhibit, the original specimen of Mauve, the historic discovery of the late Sir William Perkin. The visitors were also interested in the display of ancient appliances for producing fire before the days of matches, shown in the cottage of Messrs. Bryant and May The crystals shown by Messrs. Peter Spence and Co, also were noticed as well as the puppets on the stand of Messrs. Yardley. Before leaving the King and Queen expressed to Mr. Woolcock their pleasure at what had been shown them.

We are glad to announce that his Royal Highness the Prince of Wales, President of the British Empire Exhibition, has been pleased to accept a copy of "Chemistry in the Twentieth Century," written by some of our most distinguished chemists to mark the opening of the Exhibition.

Applications are invited by the Salters' Institute of Industrial Chemistry for a limited number of Fellowships for post-graduate chemists who are desirous of adopting an industrial career. The Fellowships are of the annual value of £250 and fall vacant in October next. Applications should be received by the Director of the Institute, Salters' Hall, St. Swithin's Lane, London, E.C. 4, on or before June 30, 1924. Forms of application may be had from the Director, Prof. A. Smithells, F.R.S.

The sudden death, on April 17, of Mr. H. J. Bailey, O.B.E., F.I.C., one of H.M. Inspectors of Alkali Works, marks the passing of a prominent figure amongst South Wales chemists. His kindly qualities, conspicuous ability and tremendous enthusiasm had gained him a host of friends in this area, and chemical industry will suffer a very considerable loss on his decease. He was a very active member of the Committee of the South Wales Section of the Society of Chemical Industry. He will also be remembered by many as the writer of the section on Acids and Alkalis in the Reports on the Progress of Applied Chemistry for the last two years. His knowledge of many branches of industry, particularly of the tinplate trade, was very considerable, and his loss at the early age of 44 cannot but be deeply regretted.

The French Photographie Society has awarded its Janssen medal to Dr C. E. K. Mees and its Davanne medal to Mr. W. B. Ferguson for their contributions to the advancement of photography. According to the *British Journal of Photography*, from which the above information is quoted, this is the first time any medals of the French Photographic Society have been awarded to foreigners.

Mr. H. O'Neill, M.Met., has been appointed lecturer in metallurgy in the University of Manchester.

Prof. G. N. Lewis, professor of physical chemistry in the University of California, received the Willard Gibbs medal at the April meeting of the Chicago Section of the American Chemical Society.

R. G. VanName has been appointed associate professor of chemistry in Yale University, Conn.

Prof. Elihu Thomson, of Massachusetts, has accepted an invitation to deliver the 30th James Forest Lecture before the Institution of Civil Engineers; therefore the lecture, originally fixed for May 6, has been postponed until July 8. It is of interest to note that Prof. Thomson has been awarded the triennial Kelvin gold medal, for 1923, and formal presentation of the medal will be made during the Kelvin Centenary celebration in July.

The Appointment of Gas Examiners

In the unavoidable absence of the President of the Board of Trade, Mr. Alexander, Parliamentary Secretary, received a deputation from the Institutes of Chemistry and Physics at the Board of Trade

on May 1 in connexion with the qualifications of gas examiners appointed by local authorities for the purpose of protecting the interests of the public users of gas supplies. The deputation, introduced by Major Church, Parliamentary Private Secretary, consisted of Sir R. Gregory, Sir H. Jackson, Sir C. Parsons, Mr. E. M. Hawkins, Mr. G. Nevill Huntly, Prof. Eccles and the officers of the Institutes of Chemistry and Physics.

Sir Richard Gregory stated that the Gas Regulations Act, 1920, required the price of gas to bear a definite relation to the quality, and not only to the quantity of gas purchased; for this purpose the Act required the appointment of a competent and impartial person to be a gas examiner. It was necessary to emphasise the importance of defining the phrase "competent and impartial person," as the section of the Act which relates to the powers of the gas referees did not require them to define competency, and there was no reference in any part of the Act to such a definition. The result was that the practice of local authorities with regard to the appointment of gas examiners varied considerably. As a rule the authorities in the Metropolitan area and of large provincial cities secured for their gas examiners highly competent persons; but small local authorities, particularly in rural areas, regarded with some disfavour expenditure on this kind of service; the protection to the public from small local gas companies, often not too efficiently directed, was correspondingly reduced. He claimed that the gas examiner should be a person of similar standing to a public analyst, over whose appointment the Ministry of Health could exercise a veto, and suggested that the Board of Trade should secure this right under statutory powers. In his opinion, the higher the standing of the gas examiner and the stronger the corporate body to which he belonged, the more adequately were the public safeguarded.

Sir Herbert Jackson pointed out that the chief concern of the Institute of Chemistry, the Institute of Physics and similar professional bodies in matters of this kind was to safeguard the interests of the public. Properly qualified professional men had behind them the traditions and status of their institutions and were sensible of the grave responsibilities of their duties, and answerable to their professional institutions for their conduct.

Interesting examples were given by Mr. Hawkins and Mr. Huntly of the manner in which incompetent gas examiners might fail to detect irregularities by which the public might suffer loss.

Sir Charles Parsons pointed out that there were no simple fool-proof instruments for gas examination like those for the measurement of electrical units. Not until he was associated with Sir George Beilby at the Fuel Research Board did he realise how difficult was the task of carrying out the test with gas calorimeters; and it was only recently that he had been made acquainted with the fact that in some places incompetent people were being employed as gas examiners. Like the other speakers, he insisted that gas examiners should be persons of high professional qualifications and standing.

Mr. Marlow, Assistant Secretary of the Institute of Chemistry, in summing up, said that the case of the Institutes was that the word "competence" in the Act required definition. The point would be met if the Board secured the necessary statutory powers to issue orders defining "competence."

In reply Mr. Alexander said that the Board were most anxious to protect the public and that the representations of the deputation would receive the most careful consideration of the President and the officers of the Board. The changes in the method of appointment of gas examiners suggested by the deputation indicated the necessity for statutory powers being granted by Parliament. He was certainly not in the position to promise legislation this Session, as there were many important and overdue Bills on the stocks. He pointed out also that the Board must work in harmony with the local authorities, and that in the event of legislation being contemplated the local authorities would have to be consulted.

The deputation thanked Mr. Alexander for their reception.

International Congress of Refrigeration

So close is the mutual relationship of biochemistry and refrigeration that the fourth International Congress of Refrigeration, which is to be held in London from June 16 to 21, under the presidency of Sir Gordon H. Campbell, K.B.E., will discuss a number of specially contributed papers on the various phases of this subject.

The features of this Congress comprise a considerable number of trips, free to members, to refrigerating establishments and other sights, such as the National Physical Laboratory at Teddington, the Port of London Docks, Bristol, Southampton, Liverpool and Manchester, to which the railway companies are granting a free Congress trip, whilst the leading shipping companies are entertaining the members on vessels in dock. A large volume of Congress Proceedings will be supplied afterwards to members.

Particulars relating to membership may be obtained on application to Mr. J. Raymond, Hon Secretary General, Fourth International Congress of Refrigeration, Weavers' Hall, 22, Basinghall Street, London, E.C. 2.

BRITISH INDIA

Winter Oilseeds Crops, 1923-1924

According to the second forecast based on reports received from provinces which contain 98·7 per cent of the total area under rape and mustard, and 99·1 per cent. of the total linseed area of British India, the total area under rape and mustard is estimated at 3,496,000 acres. This is 5 per cent. below the area reported at the corresponding date of last year The total area under linseed is reported to be 2,761,000 acres, which is 10 per cent. above the area reported last year at the same period. The condition of the crops is, on the whole, reported to be fair.

FRANCE

Coke Ovens

In a recent communication to the Société des Ingenieurs Civils, Prof. Berthelot considered modern rules for the exploitation of coke ovens, discussing modern practice with regard to the dimensions of the ovens, the choice of the quality of gas for heating, the selection of refractory products, and concluded with an account of recent methods for quenching and handling metallurgical coke. It was suggested that the width of coke ovens should be reduced to roughly 40 cm. to make them more suitable for producing metallurgical coke of the best quality and to increase their carbonising power, and the height should be reduced to 3·5 m. provided devices were used to reduce as much as possible the rapidity with which the heating gas was burnt. Similarly the length of the ovens should be increased as much as possible up to 12 or 13 m., and modern methods for heating and handling, such as those of Piette or Coppée, should be used as far as circumstances permitted.

CANADA

Forest Research in Quebec

A sum of 25,000 dollars has been set aside by the Canadian Government for the furtherance of a scheme to establish a bureau of forest research in various parts of the province of Quebec. A paper school at Quebec, and one of the Government nurseries will probably be established, where methods of encouraging the growth of trees by both natural and artificial methods will be studied during the present season.
